ACADEMIC COMMITTEE OF THE ENCYCLOPEDIA

Mieczyslaw BACEWICZ- Polish Systems Society,
University of Technology, Wroclaw, Poland

Heiner BENKING, Berlin, Germany

Sören BRIER- Editor of "Cybernetics and Human
Knowing", Copenhagen, Denmark

Gerhard CHROUST- General Secretary of the
International Federation for Systems Research,
University of Linz, Austria

Daniel DUBOIS- President of CHAOS, Centre for
Hyperincursion and Anticipation in Ordered
Systems, Institute of Mathematics, University of
Liège, Belgium

John van GIGCH- Professor (Em.) of Management,
California State University, Sacramento, USA

Ranulph GLANVILLE- Cybernetics Research,
Southsea, United Kingdom

Ernesto GRÜN- President Asociación Argentina de
Cibernética y Sistemas, Buenos Aires, Argentina

Michael JACKSON- Editor of "Systems Research
and Behavioral Science", University of Hull and
Humberside, United Kingdom

Anthony JUDGE- General Secretary of the Union of
International Associations, Brussels, Belgium

Magdalena KALAJDIEVA- Institute for Control and
Systems Research, Bulgarian Academy of
Science, Sofia, Bulgaria

Gianfranco MINATI- President of the Associazione
Italiana per la Ricerca sui Sistemi, Milano, Italia

Matjaz MULEJ- President of the Slovenian Society
of Systems, University of Maribor, Slovenia

Nicolas PARITSIS- Vice President of the European
Union of Systems, Heraklion, Crete, Greece

Francisco PARRA LUNA- Facultad de Sociología,
Universidad Complutense, Madrid

Ricardo RODRIGUEZ ULLOA- President of the
Instituto Andino de Sistemas, Lima, Perú

Markus SCHWANINGER- Institute of Management,
University of Sankt Gallen, Switzerland

G.A. SWANSON- College of Business
Administration, Tennessee Technological
University, Cookeville, TN, USA

Eric SCHWARZ- Centre Interfacultaire d'Etudes
Systémiques, Université de Neuchâtel, Suisse

Robert TRAPPL- President of the Austrian Society
for Cybernetics and Systems, University of Vienna,
Austria

Stuart UMPLEBY- Center for Social and
Organizational Learning, George Washington
University, Washington, D.C., USA

Robert VALLÉE- Director of the World Organization
of Systems and Cybernetics, Université de Paris-
Nord, France

John WARFIELD, Director of the Institut for
Advanced Study in the Integrative Sciences,
Fairfax, Virginia, USA.

Introduction to the Second Edition

The challenge to reason

The first edition of this Encyclopedia has been well received and, I dare hope, useful to those who took interest in it.

During the seven years after its appearance, so many events happened worldwide, that this kind of work can now be seen in a quite different light.

I never believed that it would concern only scholars and, among them only those not affected by specialized tunnel vision.

It has not of course reached Jane and John Citizen, at least not yet.

Their world, our own world, has been however violently shaken and deeply troubled by new challenges as well as by insidious but pervasive doubts about basic beliefs and even perhaps about the very survival of our species in the near future.

As stated by Bertrand RUSSELL (quoted by Søren BRIER): "The whole problem with the world is that fools and fanatics are always so certain of themselves, but wiser people so full of doubts". This is still truer today than it was when Russell was observing the confuse and confusing spectacle of mankind, i.e. until his disappearance in 1970.

Meanwhile the challenge to reason is worsening day by day. It is not merely its negation by the "fools and fanatics". As Stafford BEER pointed out, it has even more to see with the ill-informed, sloppy and/or devious use of reason itself. Moreover such a fake rationality is frequently put at the service of ill-conceived (and in cases, abusive) designs, proposals and decisions. Just to take an example, let us ponder the massive Aral Sea disaster. ("see site <http://www.dfd.dlr.de/app/land/aralsee/>)

We are evermore victims of what Jean FOURASTIE called "the ignorance of ignorance" (much worse than simple ignorance, as it leads to insolence and imprudence). In a similar way we sink into the swamps of "underconceptualization" (John WARFIELD)

Personal musings on the systemic path

Now, how could Systems and Cybernetics be of any use about all this?

Of course, it could help to ward off the territories of ignorance and deepen the understanding of what happens, and why we are generally so helpless about it.

At least my own inquiry has brought me food for thought about a number of brand-hot present issues.

Only one example will do. I became in the recent years more and more interested in the so-called neural networks, as models for multi-

ple interactions among a great number of elements within a specific area of activity and in accordance with some rules of communication and action.

I quickly discovered that neural networks could help to transform analogies into models for very different kinds of situations. They better the understanding of insects societies, but also the propagation of epidemics (AIDS for example) using the complementary model of "small world". They better explain the progress of forest fires, or stock market crashes, or the swift diffusion of ideologies or fads, with the help of "memes". It makes clearer the changing world economy, or the workings of the world-wide electronic web.

It also changed the understanding of this editor about communication means and codes, be them pheromones, pathogens, money, electronic pulses or human languages.

Many other examples of this kind could be offered.

The conceptual toolkit in perspective

In short, systems and cybernetic models, when organized into a coherent language, become an exceptionally valuable methodological toolkit for the study of any complex issue.

By the way, let us not anymore sink into the morass of controversy about so-called "theory of systems", what it is or not, what it should be or not. The topic is of course interesting, but it should not detract us from practical purposes, nor make us appear as abstruse and inconsequential.

As the spanish philosopher Ortega y Gasset once said, let us go to the "matters" ("a las cosas", i.e. to the issues at hand)

It is nevertheless also important to understand that systems thinking (and acting) introduces a new approach to the "matters" and is arguably the most significant conceptual mutation in Western thought, at least since Renaissance.

I tackled this subject in my 1997, 1998, 2002 and 2003 papers, in order to make clearer my own mind (and hopefully my readers minds) about the deeper meaning of this new way to manage our ideas and behavior.

In this sense, I am struck by some significant aspects:

- Systems thinking operates a general mental and psychological re-orientation (or "re-polarization") that implies a kind of impulsive self-reference about one's own way of thinking. This leads to the conscience of a conceptual implicate order (more or less in the sense of David BOHM's cosmic implicate order) in which the more specific "explicate" models create from specialized or discipli-

nary viewpoints, can be connected and put into a general perspective.

This is at least the feeling I acquired after more than 45 years of reflexion on the subject.

- In a parallel way, the "world out there" (of Heinz von FÖRSTER) has been massively transformed during the last 150 years through the impact of a more and more extended use of energy. Thousand of small, and more or less isolated communities and tens of supposedly "independent" nation-states are being forcefully connected within a "one world" in the making (as clearly seen already by Wendell WILLKIE, unsuccessful US presidential candidate in 1940.)

This is at the same time a "creative destruction" process (Joseph SCHUMPETER) and the emergence of a hyper-complex whole system through "dissipative structuration" (Ilya PRIGOGINE). Both aspects reflect a powerful new structural dynamics.

- Caught in the throes of such a dramatic transformation, human societies seem to suffer a kind of overpowering social pathology and are probably starting to undergo a groping immunological process somehow similar to the biological acquisition of antibodies.

- In my opinion the appearance of systems and cybernetics thinking during the 2nd half of the last century is an important- and possibly even one of the decisive events in this self-protection process. In fact, it is obvious that the ongoing deep and general transformation of man and societies evokes and tends to produce new ways of thinking and acting. Similar processes have been observed worldwide all along the historical evolution of societies and their cultures.

The progress of systems thinking

A significant evolution during the 10 to 15 more recent years has been the nascent and/or growing interest in systems thinking in countries where it was practically unknown, or at least undeveloped.

In Europe for instance, very useful work has been produced in Belgium, the Czech Republic, Denmark, Finland, Greece, Poland, Russia, Slovenia and Switzerland, in addition to what is done since many years in Austria, France, Germany, Hungary, Italy, the Netherlands, Spain, Sweden and the United Kingdom.

Meanwhile Canada and the United States remain fully active.

Another very important development is presently taking place in China, Korea and Japan, where significant correspondances are discovered with the traditional oriental philosophies.

Latin America is also waking up. The oldest systems society, the argentinian, is now in good company with the active peruvian one and more informal groups in Brasil, Chile, Colombia, Mexico and Venezuela.

Signs of activity have also been registered in Australia, New Zealand and South Africa. In all these countries original work is produced and interest is growing.

In short, we seem to be on our way toward a worldwide awakening.

Now only Central and North Africa, the Middle East, Central Asia, India and Indonesia remain largely absent

The foregoing "stock taking" could indicate that we are slowly nearing the critical mass needed if systems and cybernetics were to be recognized as useful mental and practical tools.

The Road ahead

Of course, we still need to fulfil some basic conditions before reaching such a stage in our progress.

1) Concepts and models must be translated into specific methodologies for design and action in administration, business, ecological and social issues, and politics. What has already been achieved must be diffused much wider.

The United Nations and specially UNESCO would have to play an active role in such translation and diffusion of the results.

Unesco already made a good start with the edition of the small but substantial books on education by Edgar MORIN and the publication of the "Encyclopedia of Life Support Systems" (EOLSS), whose conceptual foundation is systemic.

The Union of International Associations (Brussels) possibly could still expand its valuable Encyclopedia of World Problems and Resources, which structural organization is also quite systemic.

2- All that has been gathered until now in systemics and cybernetics must be transmitted to the new generations, who will need it still much more than their predecessors.

If this is not done, they would lose critical years to rediscover an already existing knowledge, ready for use, and on which they could start creative work of their own.

3- The already disponible information should be ordered and made available in more easy and convenient ways.

The quite limited diffusion of the systemic and cybernetic journals (some of which have even perished) is completely insufficient.

Much more should be done, particularly by creating a general repository of all existing past and present material. And of course, the www. should be used in a much more extensive (but precise) way.

Moreover, notwithstanding the fact that english is now the "lingua franca" of communication, the information needs of non-english speakers or readers should be taken care of.

As conversation and creative debate at all levels and places are essential, adequate basic material should be produced in the most important languages: arabic, chinese, french, german, italian, japanese, portuguese, russian and spanish. Ideally the list should also include bulgarian, hindi, hungarian, iranian, kiswahili, malay, polish, rumanian, turkish and urdu.

The International Federation for Systems Research (IFSR) could play an important role, helping those who would like to translate significant papers and books into their own language, or produce original information of general scope.

In this Encyclopedia's second edition, at least much more references in french, german, italian and other languages have been included.

But anyhow this will be useful only for those able to read this book in english, to begin with.

On the other hand, the inordinate proliferation of information and particularly doctored pseudo-information that characterizes our present time is now a problem in itself. Until-let us say- 1950 lack of information was the main hindrance.

On the contrary nowadays we are in danger to drown in a deluge of propaganda of the most various intentions, as well as proposed "good for all" models or pseudo-models offered by so-called "gurus".

From one side, our disponible time to gather information is strictly limited. We are thus obliged to select those inputs that are really significant and seem potentially useful to us. This is in itself a time consuming process.

We need also to adapt and readapt more and more frequently to shifting conditions in general and in our specific field of activity. As said by Gerrit BROEKSTRA, "no fit is forever". He could have added..."not even for long time".

Conclusions

Accordingly, Systems thinking does not offer recipes for "solutions". What it proposes is a methodological approach that help us to conduce our thoughts in an ordered, renovated and more efficient way when confronted with new issues that are much more intricated and wide-embracing than even in a recent past.

In short, we must reconstruct our own mental and psychological competence if we are to assume efficient and personal responsibility in our behavior and decision making. If not, we would merely contribute to the growing general disorder and evermore turn into helpless social puppets. This is indeed also becoming true for the very puppeteers who believe that they all-pervasively control our strings. In fact we have frequently seen their power slowly eroded, if not suddenly destroyed by the unexpected reactions (for them!) of the social groups or systems that they fancied themselves to manage at will. This was the final fate of nearly all of the major political leaders during the last century.

As a conclusion, preparing this second edition has been for me a constant process of self-critical thinking. I had to evaluate in a recursive way what was significant, and how, and why, and applicable to what and when... and also what is connected to what else and in which stable or transient way. Moreover, integrating new ideas to the already existing material was frequently an arduous process.

Finally, the global result is again merely offered as "food for thought", but now also more intended as tools for reflexive and responsible intervention in better understood situations and issues.

I must once again tribute my gratitude to the many friends who helped me in a way or another to prepare this updating; to the valuable support of the International Federation for Systems Research, to my patient publisher, and once more to my wife Gloria in her triple quality of librarian, typist and generously understanding spouse.

Charles François, June 2004

INTRODUCTION

"Socrates complained about writing. He felt it forced one to follow an argument rather than participate in it, and he disliked both its alienation and its persistence. He was unsettled by the idea that a manuscript traveled without the author, with whom no argument was possible. Worse, the author could die and never be talked away from the position taken in the writing" (Alan C. KAY, *Sc. American*, sept. 1991)

"It is the confusion of (the) different meanings that causes an intolerable babel ruling out any possibility of the strict explication of appropriate concepts. We believe that the way out lies in singling out that part of the content of these concepts which makes them specifically systemic ones, and in carrying out the necessary systematization on this basis" (I. BLAUBERG et al., 1977, p.287")

My first motive to start compiling a "Encyclopedia of Systemics and Cybernetics" has been grounded in my own doubts about various aspects of these new approaches, as reflected in the writings of numerous authors.

To begin with: Why did they appear and why did they so during the second half of this century?

We can perhaps go back to the founding fathers. Ludwig von BERTALANFFY was obviously wondering why very similar concepts and models were appearing independently in many different disciplines. And which was the basic nature, of such similarities? It seemed that some common substrate existed and, being this the case, that it could be useful for creating valuable synthesis and short-cuts in a number of disciplines.

BERTALANFFY never stated very clearly that all "systems" have in common their complexity, which is different and much more than complication, because it reflects some basic and coordinated types of internal organization and interesting similarities in the basic nature of external contexts, whatever their particular nature. He did however perceived these general features as the common basis for his inquiry.

As to Norbert WIENER - particularly inclined to mathematics and engineering - he observed the seemingly universal character of some specific relationships, that could be modeled through similar mechanisms in very different kinds of systems. He thus introduced feedback, leading to the basic notions of "Control and Communication in the Animal and the Machine". It became immediately clear that the feedback relation implied a closing loop, leading to nonlinearities and complex devices, that could be found in natural organisms or created to steer artifacts.

It is now confirmed that "complexity" is the master-concept. Emergence of complexity:

- 1) paralleled the emergence of a better perception of complex systems in nature (Living beings, ecosystems, animal societies) and man-made (in business, economical, social, political).
- 2) led to the dawn of our understanding of the intricate character of natural entities, either closely packed (a plant, an animal) or loosely interconnected (biota).

I have in this way been driven to the conclusion that Systemics and Cybernetics were interconnected and adaptive responses to complexity, either newly built in artefacts, or newly perceived in nature.

A serious problem for me, and probably for most of the would-be users of these new approaches has been the piecemeal appearance of numerous concepts and models, all somehow referred to complex entities, but in a haphazard and unconnected way. In effect, many systemic concepts have been elaborated under various guises and from different viewpoints by a number of systemists, or even by non-systemists. In some cases the correspondences are less than obvious, and many are probably yet to be discovered.

For example, as an afterthought, feedback seemed to be somehow related to dissipative structuration and hierarchies; variety to control; information to entropy; entropy to dissipative structuration; information to variety; etc... But these "somehow" should better be explained!

Many authors brought in numerous new notions, but it seemed to me quite difficult to find the significant linkages between them all. While, after all, a science of complexity must necessarily be complex itself, the crux of the matter is to discover a meaningful conceptual structure for the whole, if any.

Another very serious problem is that even nowadays, most self-styled "systemists" are interested in Systemics and/or Cybernetics only within the limits of their own disciplinary activity. This is understandable, but by doing so, they cut themselves out from the main and most important meanings of the new approach:

- a) a general understanding of their personal location within global science and global society;
- b) the emergence of a meta-language opening the real possibility for conversation, and most important, for true transdisciplinary conversation.

Such metalanguage is now a much needed tool to compensate for the growing Tower of Babel syndrome which is a very unfortunate result of the evermore reduced and particularist scope

of an ever growing number of very specialized disciplines, whose increasing isolation was already denounced many years ago by Kenneth BOULDING.

It must however be recognized that the systemic movement still suffers from chronic un-systemism also denounced many years ago by Margaret MEAD, at the time President of the S.G.S.R. ("Who shall systemize the systemists?"). There exists practically no global overview of the whole field, even if some quite synthetic theories have been proposed (MILLER, HAKEN, SABELLI, Mc NEILL, for instance).

It seemed of utmost importance to try to put together a kind of encyclopedia about the systemic approach, embracing as much information as possible in order to:

- create an introductory compendium and source book for any interested newcomer
- put information until now widely scattered in time and space at disposal of seasoned systemists.
- open the field as a whole to comparative and creative debate.

Accordingly, the three basic aims of the encyclopedia are to define (when possible and useful); to comment and discuss; and to interconnect systemic and cybernetic concepts, models and meanings. This last aspect is properly the systemic one.

Practical realism has been another important motive to tackle this work. I had to see myself with many critical real life situations, including war, civil strife, decolonization, transcontinental emigration, authoritarian regimes, learning new languages and trades, enduring painful personal losses, etc...

I am also very much afraid that the present slide towards a general and worldwide crisis of civilization has still to reach its nadir - perhaps with a global ecological crisis in a still more or less distant future: 50, or 100 years?

Meanwhile, the present situation is characterized by a piecemeal approach to all complex situations, generally commanded by short-term political or economic expediency, if not downright by strictly limited personal goals (many times non-sancti). This is a trap from which escape will prove very difficult, and probably impossible without previous vastly-embracing "educative" catastrophes. If and when these occur, the short-term and narrow view will prove useless and the systemic understanding could become a decisive factor, if clear-minded and very courageous people happen to be at hand. Our present responsibility is to handle over "food for thought" to the new generations.

Accordingly, I feel it very important that systemics and cybernetics as a new "Weltanschauung" should as quickly as possible ex-

pand out of Academe. We - i.e. all of us - will evermore need good models of complex situations, that cannot anymore be understood, evaluated and amended by the exclusive use of our present linear and reductionist models. Some examples of such situations are: underdevelopment; the universal squandering of resources; the worldwide spread of unemployment; the hothouse effect; the new paludism and tuberculosis crisis and the AIDS one; the general ageing of populations; the growing cost of technified science, particularly medicine; the ethics of genetic engineering; etc, etc...

Accordingly, this encyclopedia also aims at transmitting systemic-cybernetic models and concepts to Jane and John Citizen, who need them urgently, and most of all to their children and children's children, who are going to inherit our blunders and our sins.

Consequently, I am impatient with esoterism in Systemics and Cybernetics. We need to be understandable if we want our models and methods to reach the decision makers who really could use them and probably will need them urgently in the coming years. They specially include spiritual and institutional leaders, managers, politicians, and educators.

I thus personally deplore the multiplication of terminology derived from the old Greek language: "Autopoiesis", "Homeostasis", "Isomorphy", "Stigmergy" and the like, which could have perfectly well been replaced with plain English wording: "Self-reproduction", "Stability within limits", "Total similarity", "Transmission through environmental context". Accordingly, I introduced and discussed such terms only because they bear real significance or are widely used as a kind of shorthand, while no plain English substitutes are known.

After 40 years of learning and thinking on systems, I still discover new aspects and insights into the systemic perspective. I have slowly reached the conclusion through personal experience that Systemics is the most important mental and psychical mutation since at least the Renaissance, and possible the Presocratic philosophers and, in a worldwide perspective, since Buddhism, as a philosophy, and Chinese Confucianism and Taoism.

Also, after 60 years of being in four continents a more or less willing or unwilling actor and/or witness of this troubled finishing millennium, I must conclude that mankind is still far from the point where a sufficient number of people will acquire a reasonable non-magical and non-ideological understanding of the world they live in, even if general information and consciousness have very much progressed nearly everywhere since 1940.

Insofar as Systemics may further such understanding, and as much as my best ability will allow me, I feel a responsibility to cooperate to this progress.

Personal limitations

This work has been prepared in Argentina by a French-speaking Belgian citizen, who never lived permanently in any English-speaking country. This implies some limitations... but also some advantages.

Nearly nowhere in South America is it possible to find any printed material on systems and cybernetics in English (and even in Spanish, very few translations are available). As a result, I depended basically on what I was able to find out for myself in Europe and the States, or on what important systemists leaders, or personal friends have been kind enough to supply me, as for example a photocopy of some specific out of print work!

As a former and now retired officer of the Belgian Foreign Service, I was also never a member of any university or college staff. Consequently, I had, and have still now, to cover personally all expenses related to Systemics and Cybernetics, as for instance subscriptions to journals (which are becoming evermore costly), participation to meetings, travels, etc. This has been a sometimes severe limitation.

While most of my sources are the original ones, I also had to rely on quotations, or on translations (for example from Russian), or even worse, retranlations, when the original was unavailable, out of print or out of my reach. This has been signaled in every case. I translated myself numerous quotations from French authors, as well as a lesser number of others from Dutch, German, Italian and Spanish. In every case, a considerable effort was made to reproduce the original meanings as best as possible.

Moreover, I am well aware that a given source may not be the original one, nor possibly the most up to date. I simply used either the best (in my opinion) to my knowledge, or the best one at hand. In some cases I did not return to the original authors, using instead some clear and synthetic summary by a recent author, who sometimes clarifies a subject better than the original author, who can be obscure or esoteric, or as Socrates feared, alas not anymore able to follow any "argument".

I did not introduce in the encyclopedia logical and mathematical formalisms for various reasons. The first one is that I do not feel really qualified to enter with any depth in this particular aspect of Systemics and Cybernetics. It is to be hoped that some other author will in a near future tackle the difficult task to gather and interconnect the works in this field by authors like LØFGREN, RENYI, VALLÉE, DUBOIS and many others.

There are also other reasons for not entering in formalisms:

- It seems more useful for the time being to try to explain the whole subject in terms understandable by lay people;

- It would be better for anybody interested in formalisms to go to the original sources, which I have tried to indicate in every opportunity.

To whom this work is addressed

Paraphrasing POPPER on rational arguments, it could be said that people will not be moved by systemic arguments until they adopt a systemic attitude. This is of course a tall order.

It seems however decisive that any interested person should be able to find basic understandable information, collected in such a way as to avoid a very long and uncertain search in an enormous - but still probably quite incomplete - stack of scattered sources.

Accordingly, the general aim of the encyclopedia is to offer a tentative frame of reference for anyone interested. Anyhow, in Ernst JÜNGER words: "We cannot give *the* solution, as any solution is true only for who encountered it" (In his novel "Heliopolis", French translation, p.362).

Some items in the encyclopedia are quite elemental, others less so. As I see no reason why Systemics should remain restricted to higher level learning, my hope is that the work should even prove accessible at least partly at high school level for those young students who should become interested in the subject, or to any other intelligent person.

However, unfortunately but also inevitably, all that entered under the headings in the encyclopedia will not be immediately crystal clear for any user, even if great efforts have been made toward maximum transparency. Some notions are really difficult to grasp at the beginning. I myself needed many years to obtain a reasonable command of the whole subject, admittedly and partly because it slowly came of age during my own lifetime.

It is even possible that some concepts or models which presently appear to be significant could be seen as trivial or dubious in the future: in such kind of work, some risks must inevitably be taken.

Basics: What does Systemics means

The really fundamental meaning and usefulness of Systemics is the acquisition of a new (but complementary) way to look more globally at the world, i.e. J. de ROSNAY's "Macro-scope".

The mere use of some systems concepts or models applied to any specific situation is generally useful. But this should be only a very partial and insufficient response to the real challenge, which is the fabulous increase of complexity and the multiplication of complex situa-

tions that urgently demand a most global synthesis capability for understanding, forecasting, planning and coherent action.

Systemics, combined with Cybernetics, offers a holographic view of the real world, i.e. every systemic concept contains implicitly significant aspects of some or many other ones.

Only a more or less extended set of systemic models and/or concepts contains the essential of Systemics. However a start can be made through the serious pondering of any of them. Purely scholastic or reductionist exclusiveness is thus blocking systemic thinking and is anti-nomic to its essence.

Systemics implies a willingness to explore analogies and metaphors, in a critical but positive spirit. Many analogies and metaphors, specially most popular ones, reflects the perception by their users of some subjacent general rule, process or structure, worth of further inquiry. This is one reason why this work is more than a simple collection of definitions.

Donald McNEIL complains that, 45 years after von BERTALANFFY's first statements, we still have no General Systems Theory.

One critical question is precisely: Does a really all embracing General Systems Theory exist? And if not, should it? And under which guise?

My - different - purpose has been to create a kind of conceptual hologram of the whole field, as it is now. This is of course no General Systems Theory. However, looking at the hologram from any angle, systems concepts will appear in a connected way, revealing I hope, the general "skeleton" (in BOULDING's words) of which a genuine General Systems Theory could - or not - emerge and become clearly visible (see D. McNEIL, 1993b)

Another bone of contention is so-called "Systems Science". In John WARFIELD's words: "Unfortunately, there is a considerable confusion about what constitutes systems science, even among people who choose to identify themselves with systems-related areas" (in "Economy and Systems Science", 1990, p.67).

The encyclopedia does not pretend to rigorously define what "Systems Science(s)" is supposed to be, or not. It tries to collect as many as possible concepts and models related to complexity, most of which appeared in specialized disciplines without any clear a priori understanding of their general value. Examples are: Punctuated Equilibrium in paleontology; Stigmergy in entomology; or Hexagonal space filling in human establishments. Some of these are even now totally ignored by most systemists who, as a result, are unable to consider them as possible general models or concepts, fit to describe and, if possible, explain a number of situations in a number of different fields.

In any case, global or total knowledge is now impossible at the individual level. It should be replaced by as global as possible collective coherence in acquired knowledge, through conversation (which is in itself a systemic tool - G.PASK).

Outside her/his own professional specialization, a systemist is always treading a mine field when she/he refers her/himself to some really specific research. However, one of her/his most significant role is to create conceptual interrelations. This is not easy and, accordingly, one must more than once use prudent qualifications as for example "possibly", "probably", "could", "should", "seems to", etc...

This is the price to pay for advancing some speculations that may be stimulating and potentially useful.

Another point is that it is self-defeating, ill-advised and finally useless to try simply to convince specialists to become generalists. Specialists know best about their own work, which moreover is necessary and of utmost practical importance. This fact should be recognized once and for all, in order to eliminate a needless cause of controversy. The real point is to interconnect specialists and provide them with a meta-language or lingua franca in order to make them able to tackle *global* and *complex* situations, in collaboration with non specialized people, mainly managers, administrators and politicians, who also need systemic concepts and models in their own right.

The historical triumph of reductionism, manifest in our everyday life, led to a narrow technocracy, which tends regularly to micro quick fixes and empirical tinkering, or even brushing the problems under the carpet.

Many systemists should however share the blame, as their response has been too frequently a short-sighted, hostile and superficial critique of "reductionism". We should return to a 1984 paper in which L. TRONCALE established a list of performance criteria for "General Theory of Systems" (not "Theory of General Systems"), which unfortunately has been widely ignored.

From another perspective, it appeared to me with growing evidence that it is not possible to construct a systemic-cybernetic language without constant reference to the general conditions of existence of *any* language. This explains the presence and emphasis in the encyclopedia on semiotics (PEIRCE, ECO), general semantics (KORZYBSKI) and generally many psychological references to forms of learning; acquisition of meanings; to meanings of meanings and to their representations (WHITEHEAD, RUSSELL, BATESON, PIAGET, WATZLAWICK, von FOERSTER, von GLASERSFELD, etc.)

For similar reasons, systemic epistemology has been given wide attention, as it seems basic in order to stabilize Systemics as a scientific methodology. Accordingly, along the formerly

quoted authors, BUNGE, GÖDEL, van GIGCH, ROSEN, WARFIELD, and others have been given serious coverage, even if some of them are, or were, not specifically known as practican systemists.

Generally, the meaning of most of the formal mathematical and logical basements of systemics are still somewhat enigmatic. This is the case with fractals and self-similarities, cellular automata and self-reproduction, fuzziness, catastrophes, chaos, dissipative structuration, GÖDEL's incompleteness, BREMERMAN's limit, CHAITIN's algorithmic incompressibility, HEISENBERG's indeterminism, etc... As commented by John CASTI: "Ascertaining the exact nature of the relationship between a real world phenomenon and a mathematical model of that phenomenon is probably the most fundamental problem in theoretical science" (1984, p.282).

On the other hand, Systemics and Cybernetics are still widely in a state of flux. It is therefore difficult, and even possibly unsuitable at the time being, to fix them very well defined boundaries. As discovered by this compiler during his evaluation work, systemic-cybernetic semantics, epistemology and ontology are still in process of formation. Some concepts or models have somewhat fuzzy meanings (for example, "Preadaptation"). Some others seem to overlap (somewhat, or much). Some other ones are not, or not yet really general, or did not yet become fused with some other ones of general meaning ("Catabolism"?). These are good reasons to remain flexible.

One of the main aims of the work is to contribute to what John WARFIELD calls "referential transparency", here in Systemics and Cybernetics. This is no mean task, and I do not fancy to have it completed. However I have gathered a considerable number of elements that will probably be useful in order to come closer to transparency. In any case, a deeper understanding of some very important concepts, as for example those enounced by von NEUMANN, ASHBY, von FOERSTER, PRIGOGINE, MATURANA, to cite only some, is a must. The spirit of the work is to incite the user to go to the sources.

D. McNEIL rightly observed that an encyclopedia, specially an alphabetic one, cannot be a substitute to an integrated view of Systemics. This seems correct to me even if I tried to emphasize global views by cross-referencing and clustering. I hope that the present work could at least be a stepping stone:

- for those who want to acquire a basic understanding of the systemic approach;
- for anyone who would wish to attempt for her/himself LASZLO's "Great synthesis", i.e. not merely adding some specific view on systems.

My view is that the encyclopedia should be a linguistic and semantic system in the sense of de SAUSSURE: "An organized totality, made of

solidary elements, that can be defined only reciprocally in relation to their place in the totality". Only a frequent and critical use of such a language can produce a reasonable understanding of the ways meanings are interconnected or correlated.

Synthesis, as understood here is not a limiting or purely classifying one, but on the contrary, an open one, a multi-combinatory one. While the language as a whole acts as a global determinant, it allows also for a limitless open space for present and future variations: those produced by myself, and all those triggered in every user's mind.

In every case, I strenuously strived for clarity. No single quoted item entered the work without having been pondered. When necessary, comments and critique have been added, hoping to better the understanding of any notion that would possibly seem obscure for the reader. However, again, nothing can replace reference to the original authors.

Finally, I have tried to give a voice to as many people as possible, including many non-anglo-saxon authors, while still respecting the preeminence of the main concepts.

I tried also to interconnect various streams in the field by sometimes using information from less well known sources, as well as some frequently left aside because of language, or geographical, or simply diffusion problems. Examples are the Namur triennial International Congresses of the International Association of Cybernetics, or the works of the Systeem Groep Nederland.

Conceptual contents

Before taking any decision about anything, we need to acquire an as good as possible knowledge of the system about whose future we want to decide, the conditions that may influence it, and have an idea of its possible futures. In P. ALLEN's words: "... the necessary precondition to a discussion of policy is to have a model", and such a model, as a rule, must be dynamic and nonlinear.

Accordingly, what *practically* matters in Systemics and Cybernetics is the combined use of concepts, analogies, homomorphies and isomorphies to construct complex models of concrete systems.

In consequence, I adopted a quite extended and many-sided view of the work's content.

Many not well known terms have been included, in accordance with the following criteria:

- that the term really introduces some significant systemic meaning, or at least some specific shade of meaning, for ex. H. PRAT's "aura", or P. GRASSÉ's "stigmergy";
- that it has been at least sometimes used in the literature, for ex. R. GERARD's "artorg" or L. TRONCALE's "discinyum".

- that some significant relation to systemic situations could be found, as for ex. through G. CHAITIN's "algorithmic compressibility".

From another perspective, strictly speaking, a more or less limited systemic definition of "organization", for ex., could be given. However, many systemists offered complementary views on organization (ACKOFF, BEER, BOULDING, BROEKSTRA, LEMOIGNE, MILLER, SIMON, VAR-ELA, etc...) and this multi-dimensional perspective is so rich that it cannot be ignored in a work that tries to reflect as best as possible the wide content of Systemics.

It has also been taken into account that, between 1954 and 1997, a slow shift in systems terminology has taken place, as a commendable result of a progressive improvement of systems semantics, elimination of ambiguities, or even misleading uses of the original terminology: the differences between models of an isolated, a closed and an open system, or the precise meaning of "positive" feedback, are examples.

Some items of a seemingly very specific or specialized character have also been introduced (for example: "monoculture" - from Unesco-Unep Glossary) because of their general importance in systemic situations. On one side, this connects valuable information of special character to the mainstream of Systemics, with interesting generalizing possibilities. On the other hand, it may lead specialists to a better connected understanding of their own field.

Some terms were included:

- because it seemed useful to seek their meaning in the systemic perspective. This has been specially the case of some human sciences terms, like "ideology", "norm", or "value".
- as they seem to carry a potential for a general systemic meaning: "swarm", "symbiogenesis" or "Umweltlehre" are examples.
- mainly because they lead to a better understanding of the practical meaning and use of their *implicit* (and sometimes even enigmatic) systemic significance: "ethnocentrism", "parable of the boiled frog", or "Saint Matthews principle".
- for their practical value, as for example: "disasters: a systemic view", "patrimonial accounting", "perverse effects".
- because, while closely related to a specific discipline, their more general systemic nature, aspects or character are becoming more and more obvious: "anabolism", "autokinesis", or "catalysis".
- because of their relevance to Systemics for some particular reason: "Club of Rome", as a user of Systems Dynamics; "culture" as interpreted in systemic terms; "Dictyostelium discoideum", as a biological example of self-organization and sociogenesis.

A number of terms in the encyclopedia are related to para-systemic, or even anti-systemic views. They have been introduced for reasons of epistemological clarification, as it should be very difficult to understand some aspects of Systemics without the background of non-systemic situations or attitudes as "linearity", "reification" or "reductionism".

Some other terms have definite systemic and, simultaneously some non-systemic meanings, whose limits must be considered. An example is "memory".

A number of more or less technical terms were introduced because they are systemic in an implicit way or could be considered from a systemic viewpoint, even if many practitioners are working in a non-systemic style. Examples are: "research and development", "risk analysis", "sustainable development".

Some other terms, as for example "forecast", or "prospective", are used as stepping stones to define a systemic way of research and inquiry into the topic.

More items were incorporated, not so much for their intrinsic specialized interest (which may be considerable), but for their general systemic significance: "hysteresis", "Kondratiev cycle", "semiology", "thermodynamics", etc...

Considering their importance as modelization tools, logical and mathematical concepts related to Systemics have been presented, at least in general terms: "Boolean nets", "catastrophes", "chaos", "graphs", "KAM theorems", "neural nets", "topology", and others.

Superpositions in terminology have been discussed. Frequently different authors converge toward a systemic phenomenon through different ways. For example, the shaping of a system on a higher level of organization is termed by LASZLO as "emergence", by TURCHIN as "meta-system transition", by PRIGOGINE as "nucleation at bifurcation points through dissipative structuration", by researchers on networks as "spontaneous organization", etc... None of these concepts should be left out, as they give a kind of holographic view of various aspects of this type of phenomena. Even J. MILLER's taxonomy of living systems can be viewed as a photograph of the results of emergence.

Consequently, the encyclopedia is somewhat redundant, and intentionally so, as it is not possible to assimilate any systemic set of concepts without viewing these again and again from different but more or less interrelated viewpoints. It is hoped that this feature will help to the globally interconnected understanding of our subject as a coherent whole network of concepts and models.

Some users will possibly think - or even say or write - that this work is a very mixed bag. This may be true, but so is that hypercomplex world that we have constructed and in which we must live, using models and concepts as

different as the golden proportion, quanta theory, chaos, or organizational closure in perceptual and psychological terms.

Many examples are given, in order to avoid a purely abstract and theoretical character that could hinder the practical (and very much needed) uses of Systemics. In effect, as I believe that the systems approach and systems methodology are first rate tools to confront present and future complex challenges, I am critical of some tendencies that could exert a negative influence on their diffusion: excesses of superfluous abstract formalisms; exaggerated claims to a superficial universalism; unwarranted attacks against specialization; tendency to use jargon, etc...

A final caveat about the evaluation of concepts seems necessary. In my own comments, I have tried to avoid *loaded* adjectives like: "correct", "convenient", "desirable", "legitimate", "reasonable", "satisfying", "valid", and the like (or their opposites) as such notions correspond to implicit personal or socio-cultural criteria that may not be universally admitted. When quoted authors use such qualifications, which have been respected, their dubious character should always be remembered.

This is not to say that I believe in the practical possibility of absolute objectivity. But I would at least like that any user should stop in his/her tracks everytime these words appear, and think for a moment about their relative personal, social and cultural meaning.

Linguistics and Semantics

We should now turn back to the Tower of Babel syndrome. As noted by John WARFIELD, establishing a satisfactory conceptual language has been in the past the condition for the success of many scientific disciplines. This was done for example by LAVOISIER for inorganic chemistry; KEKULE for organic chemistry; MENDEL and FISCHER for genetics; LEIBNIZ and BOOLE for logic; CRICK and WATSON for biochemistry; WEGENER for plate tectonics; and quite recently by PRIGOGINE for generalized thermodynamics.

Precisely, one of the problems of the systems movement is the persistently scattered character of its language, which has remained ill-connected, confuse and fragmented. Accordingly, the main objective of the present work is to correlate and unify the language of Systemics and Cybernetics, in order to transform it into an efficient tool for the study of complexity, for beginners as well as for advanced researchers.

Margaret BODEN writes: "The 'meaning' of an idea represented within a semantic net is a function of its place in the system" (1990, p.95). This is a very neat formulation of my own general concept of this encyclopedia as a network. Three aspects should be emphasized:

- Language is always a mirror for the mind and the culture. But it is not always a *faithful* one;
- Every item has a potential for multiple linkages (TRONCALE), each of which adds - or restraints - some shade of meaning;
- Semantics is also a process: the network becomes more useful and efficient when used. The encyclopedia offers a connectionist aspect, as it invites to "ramble" freely within the whole systemic and cybernetic conceptual space. It also proposes a constructivist way of use, as such a free rambling must normally lead to the progressive construction in the mind of any individual user of her/his own semantic net.

In a converging way, every concept becomes more like an attractor or the center of a semantic cluster, including what Margaret BODEN calls a "penumbra" of more or less closely related concepts (1990, p.96, 175).

There is some degree of redundancy in the whole of the work. This allows for a multidimensional view of these interconnected concepts. "Connection", for instance is not exactly or merely a "relationship". Moreover, it acquires a slightly different meaning in "connectionism" or in "connection machine". This is a useful feature to obtain a deeper understanding of the systemic language.

Some doubts should also be clearly stated.

A number of terms of frequent use have, in common language, a somewhat fuzzy character. Examples are: "action", "change", "class", "concept", "description", "effect", "learning", "object", "problem", "representation", or "situation".

These apparently quite universal and taken for granted terms should not be passed by without a short pause to remember that their meaning(s) should be pondered, as they can be less transparent than frequently believed.

In values - or norms- loaded words, there exists a kind of "semantic declination", comparable with the "magnetic" one. A non-systemic term like "democracy", for example means something quite variable according to countries and cultures. This may even be the case with a supposedly rational concept, as for example "order", or "organization". Here again we have a case for a reflexive pause.

Finally, I was not always convinced that some terms used by some systemists had really a systemic meaning. They could even in some cases be considered as contaminants in the systemic language. Not a few have however been included, generally with a critical evaluation, whose responsibility is assumed. The user should decide for her/himself.

In any case it seems better to remain open and tolerant.

I tried to alleviate as much as possible some practical linguistic problems.

In some cases, quotations from authors reproduce some combersome redaction. The original has always been reproduced without modifications, in order to strictly respect the authors work. Only in some serious cases have critical observations been made.

Most quotations are from the original texts. However in some infrequent cases, due to the unavailability of originals (out of print, out of reach), I had to retranslate to English from a translation in Spanish, French or German. This is not of course a very satisfactory method.

In some few cases, however, available original texts were not used because recent authors presented a specially clear and synthetic overview of a difficult concept. An example is K. DE GREENE crystal clear explanation of HAKEN's "order parameter" concept.

The whole work has been redacted in American English, with the exception of quotes from British or European authors, who may have used U.K. English, a feature that was respected. This is the reason why it is possible to find two different spellings in the encyclopedia, as for example "behaviour" or "behavior".

Jargon has been avoided as much as possible, as well as unnecessary (in my opinion!) abstractions: both act as a strong repellent against many potentially interested users. On the contrary, many examples and comments, some of them very close to popular common sense have been used.

The fuzzy limits of the work

What should be included and what should be rejected in such a work? There are two complementary dangers: to be too tolerant with seemingly senseless or totally redundant terminology... or to be too intolerant.

This problem has already been encountered for example in relation to biological terms ("anabolism", etc...), introduced because of a possible generalization in systemic terms that could be duly established in the future. The same difficulty appears with terminology from artificial intelligence, computer science, ecology, ethology, expert systems, etc... Even some quite general notions, related to the not so rational way we sometimes assess issues and situations, mostly considered as "obvious", have been discussed, because of some new shades of meaning from a systemic viewpoint: "change", "choice", "cost", "efficiency", "goal", "object", for instance. Other similar cases have been considered above. In general, I preferred to err on the tolerant side.

Some more specific items have been included mainly to try a critical evaluation, (as for example R. SHELDRAKE's "morphic fields"), as they may have a systemic outlook, but are not (yet?) consensually accepted in the mainstream systemic thinking.

Furthermore, I suspect that some, or even many systemic concepts and models are still to be discovered. Some mechanisms, used in a specific discipline, could be possibly given a more general character. An example is "apoptosis", a general cellular mechanism of cell self-destruction, also present in the brain of Alzheimer's disease patients. Could such a mechanism be somehow active in other types of social networks? The "stigmergy" concept, introduced in this work, is obviously an example of such possible generalizations, that could be much more than metaphors.

Undoubtly, much work remains to be done in many different directions; this explains why the encyclopedia is interspersed with question marks, an unexpected feature in such a work.

While I always tried to reproduce as fully and as faithfully as possible all authors views and concepts, it remains obvious that it is impossible within the limits of short articles or entries to express all the shades of meaning developed in a paper or in a book. Accordingly, every quoted item has been carefully referenced in order to allow and encourage the user to go to the source.

Basic information has been added on the main systemic organizations in the world.

How the work is ordered and presented

The encyclopedia was constructed by progressive accretion, "reaping" terms corresponding to models and concepts from many and very different sources.

A curious result emerged spontaneously: a number of terms and expressions started to form clusters in the two following ways:

- "Blocks" of concepts corresponding to specific theories, as for example "Catastrophe theory", "Communication", "Thermodynamics of far-from-equilibrium systems", etc. At times some isolated elements came to accrue a cluster (or various ones): "Learning matrixes" obviously are related to learning, but they also introduce insights about the concept and uses of matrixes in general.
- Clusters tended to coalesce around some quite specific notion. Examples are "Control", or "Model".

While related entries are as much as possible clustered, they are not *fused*. It seemed more convenient to neatly individualize different aspects of the same concept in order to encourage due consideration of the corresponding shades of meaning.

Even so, the general ordering of terms remains somewhat arbitrary. For instance, abstract terms describing systems are all listed under "system", as for example "system, multilevel" or "system, stationary". But specific

concrete systems are at their corresponding alphabetic place as: "social system", "socio-technical system".

Generally, in composed expressions (as for example "circadian rhythm"), the alphabetic order chosen in the encyclopedia has been selected taking into account the meaning of the most specific term - in this case "circadian". However a reminder has been introduced at the corresponding place: "Rhythm, circadian".

The fact that such a work should in principle be alphabetic has some negative aspects, as for instance the need to separate items that are co-significant.

It would be advisable for the user to move "back and forth" (M. MARUYAMA, 1994, p.X), within the network of concepts and models in order to avoid unwarranted disconnections. While this may be difficult, the possibility has been created to criss-cross the whole work by using the net of terms printed in bold. It would be interesting in the future to consider a graphical representation of interconnections by linkage graphs (TRONCALE).

Nearly every term defined or concept explained in the encyclopedia is emphasized in bold types, *everytime* it is used. Some few exceptions are terms so basic and frequently used that the use of bold would be pointless: "Concept", "Cybernetics", "System", "Systemics".

The intention in using bold for general cross-referencing is double:

- That the user may know that she/he can find explanatory comments about the term within the work;
- To induce the user to stop and think for a moment when meeting anyone of these terms: "What is really the meaning, (or meanings) of "chaos", "cognition", or "regulation", for instance?"

When, in some cases, some connections between concepts or models are not so obvious, they are specially signaled by a comment of the type: See also "...."

Some terms with a specifically cybernetic or systemic meaning are also printed in bold when used in their everyday common sense, in order to sharpen the attention of the user to some shades of their meaning. examples are: content, class, issue, means, scale, situation, survival, etc...

The use of bold characters is not always closely related to a specific meaning of the emphasized term. The word "group" appears frequently with different significations, which may, or not, be related. In many cases it is useful to ponder the sense given in a specific case in comparison with what one knows about the various possible ones.

Some terms printed in bold do not refer precisely to a specific entry, but to a closely related one. For example: "Combination", or "environmental" are not in the encyclopedia, but "Combinatorics" and "environment" are.

Italics have been used moderately, mostly to emphasize some critical point, or some personal view. When within quotations, they are always the quoted author's ones.

References in Dutch, French, German, Italian, Portuguese and Spanish have been used. When possible, the reference to the original work, or alternately to its translation in English has been added.

The following special markers have been used, in order to enhance the usefulness of the encyclopedia:

- 1) **meaning** "systemic on a wide range", or "general information"
- 2) **meaning** "general abstract or mathematical model", or "methodology"
- 3) **meaning** "epistemological or ontological aspects", or "semantics"
- 4) **meaning** "practical in human sciences"
- 5) **meaning** "more specific or disciplinarian"

Personal views, self-critique and acknowledgments

It seems only fair to admit that a number of personal views have been introduced in this work. For example: "The results of sociotechnical manipulation on any environment should be closely monitored", or: "Metacommunication frames relativize communication. This is a very significant situation, specially when metacommunication remains *implicit* as it is the case in many transcultural situations". No user is supposed to accept such opinions uncritically.

My aim has been to include practical insights into as many issues as possible. In my opinion, Systemics should be connected to complex *concrete* situations whenever possible, because many of their aspects are easily neglected by specialists and from purely technical viewpoints.

While, at a definite moment, one must decide to put a final stop to any work, it is obvious that this kind of work is open-ended. In a sense, this encyclopedia is still a kind of enormous draft, even if quite elaborated. This offers at once some negative and some positive aspects. In cases, sources could be completed or replaced by better ones. Many new information, and even some older one from still unused literature, could be introduced.

My intention is to go on incorporating more information into this work, even after publication, in order to prepare future updatings. I will gladly receive material or serious critique that users would find of possible interest.

On the other hand, being well advanced into my seventies, I would also be pleased to collaborate with quite younger systemists eventually interested in such updatings.

I consider probable that some internal discrepancies, or even errors may still be present in this final version, even after various painstaking revisions. I hope that users will find out for themselves and, hopefully, communicate me their views.

Aknowledgments are, in this case, a very difficult task. In a way, I feel thankful for the whole systemic-cybernetic community, past and present.

More to the point, this work owes much to the members of the Argentine Association for Systems and Cybernetics (or Study Group for Systems, as it is also known), to the members of the Fuschl Group, to the leaders of various international and national societies (American, Austrian, Belgian, British, Dutch, Danish, French, Greek, Italian, Peruvian, Polish, Slovenian, Spanish).

It also owes much to personal systemist friends, who I will not enumerate here because their names appear frequently within the encyclopedia... and because I would be very much afraid to unfairly forget some of them.

Last, but not least, I need to emphasize the considerable support given by my wife, Gloria NAZER, as a professional librarian and generally as a helping hand in readying the whole work.

ABDUCTION³⁾

The invention of **concepts**, or logical and mathematical conjectures through the shaping of new hypothesis.

The notion – itself abductive – comes from C.S. PEIRCE, who applied it to new concepts emerging in our mind from witnessing unusual or unprecedented **situations** in which neither **induction** nor deduction can be used. J. WARFIELD stresses these differences. According to him, the origin of newly invented concepts remains a mystery. KOESTLER proposed **bisociation** as a **model** for this type of **creativity**, which like all other types is a product of neural and cerebral **networks activity**.

G. KLIR considers the computer as a valuable instrument in the abduction **process**, because it makes it easier to look “for regularities and developing thus empirical **support** for a mathematical conjecture. When the **support** becomes convincing, it is appropriate to try to prove the conjuncture formally” (1991, p.103).

In fact, abduction precedes induction (and still more so, **deduction**). Ch S. PEIRCE observed that “induction has its role not in the forming of hypotheses, but (in certain **fields**) in testing the hypothesis arrived at by abductive inference” (as quoted by P.R. MASANI (1994, p. 45)

MASANI states for example that “statistical **inference** has to be abductive”(Ibid)

0002

ABSTRACTION²⁾

1) “A **representation** in a selected **code**, not directly reproducing the features of its **model**” (J.Z. YOUNG, 1978, p.289)

2) The search for regular **patterns** through **noise**.

As to the first definition, the “selected **code**” is of course a condition for the coherent search for **patterns**.

For G. KLIR, abstraction is: “The **isomorphic transformation** from an interpreted system into the corresponding **general system**” (1991, p.17). The *interpreted* system is already a somehow **homomorphic model** of some **concrete system**. Such **model** can then be generalized (p.73).

R. LILIENFELD quotes the Spanish philosopher J. MARIAS: “Abstract **truths** do not refer to reality”, but to diagrammatic rendering of reality... while “...thinking about the concrete... presents much greater difficulties” and “... disciplines like logic and the theory of **knowledge** would assume a very different appearance if they were to state their **problems**

in all their radicality and amplitude, so that the present forms of these disciplines would be reduced to mere chapters corresponding to particular cases” (MARIAS.1975, p.126-7, quoted in 1979, p.5).

Fuzzy sets and deterministic chaos, for example, now justifies MARIAS' views (which may have implied a critique of premature oversimplifications in social sciences) In the same vein A.G. BARTO observes: “The disposition to reify abstractions is particularly strong when abstractions have been very successful in accounting for **observations**, i.e when **models** based on such abstractions have successfully undergone extensive **validation** testing and have displayed great predictive power” (1978, p.167).

As **pattern-forming** is the progressive recognition of regularities, abstraction is an emergent **phenomenon**.

(See BERTALANFFY's comments on **categories** formation – (1962, p.71-84).

In G. KAMPIS words: “...abstraction narrows down interest from the entirety of a natural system to a *phenomenal domain*. During abstraction, usually some units of investigation are named and a **set** of observables is assigned to the natural system” (1989, p.90).

Abstraction cuts through **complexity** by selecting only some limitedly characterized aspects of the **concrete system** under study, specifically by reducing in the **model** its **degrees of freedom**. Keplerian and Newtonian mechanics, as compared with POINCARÉ's **three bodies problem**, are good examples.

G. BATESON explains thus our need for abstraction: “**Habit** can deal successfully only with propositions which have general or repetitive **truth**, and these are commonly of a relatively high order of abstraction” (1967, p.254).

The basic condition for abstraction is thus the repeated recognition of some identified **signal** in multiple circumstances (See KORZYBSKI's **structural differential**) (1950).

Abstraction can however become a conceptual quagmire: We should never forget WHITEHEAD's caveat about the risks conveyed by misplaced reification of abstract **models**.

Finally a mathematically inspired view on abstraction could also be useful: the replacement of a **set** by another with a diminished level of cardinality, this leads us again to KORZYBSKI's **structural differential** (see fig. under the corresponding article)

0003

ACCESIBILITY¹⁾²⁾⁴⁾

The possibility to reach more or less easily a place in **space**, from another point or place.

Accessibility can be studied by **graphs** modelling the different positions and routes in a specified **space**.

B. HILLIER, who created what he calls “**space syntax**” as a general theory of the social **organization** of **space** (1996), uses it practically to create an accessibility **hierarchy**, for example for a better **organization** of urban **space**.

According to HILLIER, “People use **space** intuitively, much like they use **grammar**”. This is because they have a “preference for easy journeys” (M. HAMER, 1999).

The subject is closely related to **stigmergy**. This hints to a much more general **perception** of “**space syntax**” in animals.

0004

ACCESS TIME⁵⁾

The time needed to retrieve some item of **information** stored in a **data bank** or **network**.

J.von NEUMANN gave the two following definitions of access time in a computer:

“First: The time required to store a number which is already present in some other **part** of the **machine**... – removing the number that the **memory** organ may have been storing before”.

(Observe the dubious metaphorical use of the word “organ”).

“Second: the time required to “repeat” the number stored – upon “questioning – to another **part** of the **machine**” (1958, p.31).

Both types of access time may be different, according to the **processes** involved.

In the **brain** as well, recall **processes** are not instantaneous, as if some specific **channels** have to be retraced in each case.

→ Time (Access) for a generalized meaning.

0005

ACCOMMODATION¹⁾

1.“A system's-**environment interaction** or **process** by which the **environment** satisfies the changing requirements of the system”. (B. BANATHY, 1973, p.85).

2.“A temporary or lasting modification of the **organism's structures** under the influence of external factors” (S. SALTHER, 1989, p.189-208).

These definitions are so different as to be somewhat contradictory. While B. BANATHY sees an **interaction**, SALTHER sees merely a **process** within the system. In the first case it is the system that governs the **process**, while in the second one, it is the **environment**. The **process** is probably *reciprocal*. Evolving **sym-biosis** and **co-evolution** could be examples.

In any case, functional modifications are as important as structural ones.

On the other hand, accommodation relates to *individuals* and does not normally become fixed in the genetic type, as LAMARCK would have had it (had he known the existence of genes): accommodation acts *on* the basic type, but does not modify it.

Accommodation may however become lasting, i.e. lead to **assimilation**, i.e. it may turn into the basis of a permanent **adaptation** at the individual **level**. Later on, for example through ethological **adaptation**, this may become a factor of future **evolution**.

0006

ACCRETION²⁾

A **process** of **growth** by gradual **addition** of **elements**.

In general accretion is governed by some geometric **rule** or **rules** of **space** occupancy, as for example **clustering** by **fractal aggregation**, or **hexagonal space filling**.

In most cases it also results of **dissipative structuration**.

0007

ACCUMULATION¹⁾

The **process** of piling up of some class of **elements** in a system due to a **positive feedback** in its **production**.

When this **process** turns exponential, for the lack of a countervailing **negative feedback**, it may easily destroy the affected system, as for example in **runaway population explosions**. This is due to a double cause:

- internal clogging of the system, whose **functions** become impaired, due to its excessive **density**;
- starvation of the **elements**, deprived of a sufficient **environmental flux** of **resources** to maintain themselves. The death of the starving **elements** within the system, poisons it.

0008

ACCUMULATOR¹⁾

Any device capable of storing some kind of **resource**, creating an available **reserve**.

Stored **resources** can be energetic, material or informative.

Before **storage**, some other **agent** within the system must in most cases put the **resource** in a form suitable for storing. See: "**Input transducer**".

0009

ACT of a system¹⁾

"A system **event** for the occurrence of which no **change** in the system's **environment** is either necessary or sufficient" (R.L. ACKOFF, 1972 a).

R.L. ACKOFF comments: "Acts, therefore, are self-determined **events**, **autonomous changes**. Internal **changes** – in the **states** of a system's **elements** – are both necessary and sufficient to bring about **action**. Much of the **behavior** of human beings is of this type, but

such **behavior** is not restricted to humans. A computer, for example, may have its **states** changed or change the **state** of its **environment** because of its own **program**" (Ibid).

Systems able to 'act' in this sense are **autonomous**, i.e.:

- in P. VENDRYES' terms, able to determine their own **behavior**, up to a point;
- in H. MATURANA and F. VARELA's terms, endowed with **organizational closure**, i. e. able to maintain their **identity** and internal **organization**.

0010

ACTION¹⁾

H. SABELLI defines action as "the product of **energy** in **time**". He adds: "Action exhibits two **asymmetries**; the **energy** potential and the direction of **time**. All actions share the **time dimension**, but differ from each other in at least one (**space**) dimension" (In "**Organización: Estructuras, Sistemas y Procesos**", to be published in "Encyclopedia of Psychiatry", RUIZ ALARCON, 1994) (pers. comm.).

Already in the 17th and 18th Century various European mathematicians "showed that motion and **change** were always achieved in a way that minimizes the "action" of nature. This action is a measure of the momentum and velocity associated with a moving particle and can be generalized in the case of more **complex systems**" (F. DAVID PEAT, 1988, p.54).

This principle of **least action** has reappeared under different guises in various fields, as for example **ZIPF's least effort principle**.

It is related to the internal **organization** of **fields** of forces and with the consequent **straturation** of form.

0011

ACTION AND REACTION

→ **Le Chatelier Principle**

0012

ACTION CHAIN¹⁾⁵⁾

A behavioral sequence triggered by an initial **stimulus** (see: N. Tinbergen, 1965)

Action chains are present already in **complex chemical reactions** (**Belousov-Zhabotinski reaction** is an example)

However, in order of growing **complexity** the following sequences may be given as examples:

In **Biology**: the fertilization act that triggers the creation of a new living being...and the subsequent **developmental process** (the **homeobox**)

In **Ecology**: the emission of biochemical molecules by a tree under attack of a parasite, such as the molecule acts as a **pheromone** that attracts a specific parasite of the parasite

In **Ethology**: the hormonal **stimulation** of birds in spring that triggers the whole sequence of nest building

In **Psychology**: the frustration reaction of someone unable to stage a strong reaction against some offense or aggression and substitutes it by some symbolic gesture (as for example banging a table)

Action chains should also be researched in sociology. They seem to be present in honey bees and in foraging ants for example.

The way the behavioral sequence becomes established and thereafter stabilized and transmitted through biochemical or other **mechanisms** should deserve a general inquiry.

Examples of such **mechanisms** are imprinting and innate **response**, but their **operation** is not yet clearly explained.

0013

ACTION (Ecology of)¹⁾⁴⁾

According to E. MORIN, future is not absolutely conditioned by some supposed rigorous historical conditioning. This is a kind of generalized **uncertainty principle**, (1999, p. 65-66), a wide (and even somewhat hyperbolic extension of Heisenberg's **Indeterminacy relation**).

As a result MORIN proposes two principles for an "ecology of action":

1- any action, once carried out, triggers an ongoing and very complex interplay of **interactions** and retroactions (**feedbacks**) A similar idea was already emitted by LEIBNIZ (1646-1716)

2- the ultimate consequences of an action become finally unpredictable

→ **Predictability; Prospective; Surrogate world**

0014

ACTION GRAPHS⁴⁾

"Paper and pencil diagrams of interpersonal exchanges of **energy** (labor), **information** (about self and others, affection, entertainment, practical, social and intellectual skills) and **matter** (money and property)".

These **representations**, created by H. SABELLI, in his **process theory** are applied by him to psychology and psychiatry. ("**Chaos and Society Conference**" – Univ. du Quebec, Hull, Ottawa, 1994).

0015

ACTION LEARNING⁴⁾

"A personal development **programme** where a **group** of people learn by working on real problems interactively and autonomously by questioning and reflecting in order to gain insight and **understanding** and considering how to behave/act in future"(G.S. MWALUKO & T.B. RYAN, 2000, p. 396)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The authors paper is inspired by L. WEINSTEIN's work (1995) but they propose their own systemic method for implementation.

0016

ACTION THEORY ²⁾⁴⁾

In 1970, D. SILVERMAN published a "Theory of organizations". M. JACKSON reproduces in an adapted form the "action theory" proposed by SILVERMAN, as resumed in seven propositions:

- 1- the social and natural sciences have entirely different types of subject matter
- 2- sociology is concerned with **understanding** action rather than observing **behavior**. Action derives from **meaning** attached to social reality
- 3- meanings derive from society, become institutionalized and can be experienced as social **facts**
- 4- while society defines man, man also defines society. Particular constellations of meaning have to be continually reaffirmed
- 5- through their **interactions** men can modify, change and transform social meanings
- 6- **explanations** of human actions must take account of the meanings of those involved in the social **construction** of reality
- 7- positivist explanations asserting that action is determined.

This is basically a non-mechanistic approach.

JACKSON observes that SILVERMAN's views are widely interpreted as an alternative, critical of **systems thinking**: "following SILVERMAN's lead (many **management** theorists)...explored phenomenological, ethnomethodological, marxist and, eventually, postmodern approaches to organizational **analysis** without recognizing that systems thinkers were engaged in a similar exploration in their own discipline, albeit with practical action as the primary concern (CHECKLAND 1994, GALLIERS, JACKSON and MINGERS, 1997). In return, it must be said, systems thinkers largely ignored what was going on in organization theory" (Ibid, p. 65-66)

→ **Autopoietic systems; Consensus; Conversation; Observer; Social system (Human); Social order parameters; Stigmergy**

0017

ACTIVATION ENERGY ^{1) - 2) - 5)}

The energy needed to start a **reaction**.

This notion comes from chemistry: A certain minimum **energy** is needed to prime any **reaction**, which may then become self-maintained, or tend to come to a standstill, or run away as in an **explosion process**.

It would be interesting to explore **analogies** in ecology, economy and society. Many **processes** affecting systems in these domains seem to be **triggered** by some more or less

precisely definite **input of energy**. However it also seems that these **phenomena** are very poorly understood and that in some cases disasters may result.

→ "**chain reaction**", "**enthalpy**", "**runaway process**".

0018

ACTIVATION (Forward) ²⁾

The effect of a **feedforward** on a system endowed with a **predictive model** of itself, its **environment**, or both.

In order to avoid any **paradox** about a supposed "influence of the future upon the present", the concepts of **anticipatory behavior**, **feedforward**, **preadaptation**, and **predictive model**, or **predictor** should be carefully pondered. (R. ROSEN, 1967, p.11-23)

0019

ACTIVATION (Spreading) ²⁾

A **pattern of activity** in a **network** that propagates from the input side to the output side, producing a **response** to a **stimulus**.

This **process** takes place in local processing **nodes** inside the **network**.

0020

ACTIVITY of a SYSTEM ^{1) - 2)}

"The ensemble of the variations in **time** of all the quantities under consideration at the given **resolution level**" (G. KLIR, 1965, p.30).

G. KLIR points out: "The **time** interval of the activity is either the entire interval during which we observed the relevant quantities (in the experimental investigation of the system), or the interval in which the variations in **time** are given and are to be realized" (Ibid).

The **distinction between levels** – for instance **micro-**, **macro-**, or **megascopic** – corresponds to the fact that **actions** very limited in **space** and/or **time** (in relation to the defined **observation level**) are **generally** not significant at a higher **level**, because they normally lack the sufficient **range** to have an impact on **processes** of considerably greater **amplitude** and/or much longer **frequency**. It may however be difficult to be sure that any **action** or **event** at a given **level** is not going to make a great difference, as in **chaotic phenomena**.

Indeed, in the proximity of an **instability threshold**, a quite small **action** even at a lower **level** can trigger a decisive **discontinuity** or **bifurcation**.

These quite abstract **models** can seemingly be observed in **concrete systems**, for instance in some ants societies where distributed **processes of task allocations** by **roles** switching have been discovered by D.M GORDON (1995, p.50-7) This seems to take place by a reciprocal and collective needs **assessment** leading to the global activity of the system.

→ "**constructs (synchronous)**"

0021

ACTIVITY PATTERN (Rhythmic) ²⁾⁴⁾

Rhythmic activity patterns can be observed in many natural **phenomena**. Some examples are: Oceanic **waves and tides**; plants **growth**; activity in beehives and, probably, some types of human activities.

According to B. COLE, "... isolated individuals and individuals in sparsely populated **groups** have a pattern of activity-inactivity that is described as **deterministic chaos**. This is not a **random** pattern, but one which is so complex that it is impossible for an **observer** to predict what a particular ant will do next" (in B. GOODWIN, 1998)

Such **complexity** must depend on the **interactions** among individuals, which become reciprocally constraining, but with considerable leeway due to their scattering and the differential **delays** in their reciprocal **perception**.

GOODWIN and colleagues did modelize ants **behavior** through a **neural network of cellular automata** (p.34).

They observed that the **output** of the **network** was **chaotic**. Moreover, "increased **density** of individuals increases the amount of activity by individual, simply because of the higher **frequency of stimulation** between individuals..."

So model ants, behaving chaotically and interacting 'socially' by **stimulation**, can generate a collective rhythm through a **colony**. This is a clear example of **emergent behavior**... " (p.34) And "... the **model** showed that there is in fact a wide **range** over which the **sensitivity** can vary and still produce collective rhythms. This suggests that rhythmic activity patterns are robust consequences of colonial living. They may in fact be hard to avoid. Collective rhythms is an **emergent property** that has been described as "**order for free**" (p.34).

This could be usefully compared with the onset and development of the "**social phase**" in *Dictyostelium discoideum*, and is probably significant in numerous other gregarization **phenomena**.

GOODWIN adds: "There is another important property of colonial rhythms that the **model** revealed. Rhythmic activity emerges suddenly above a **critical density**. But what type of **discontinuity** are we dealing with? The **model** showed that it has the characteristics of what physicists call a **phase transition**: a sudden **change of state** from one type of **order** to another... At the **critical density**, what was a collection of individuals doing their own local thing begins to change as global **order** emerges via activation **waves** that propagate through the entire **colony**" (p.35)

0022

ACTUATION RULE ^{1) - 2)}

A behavioral rule automatically learned from experience by an intelligent system.

This concept is introduced by W. FRITZ (pers. comm.). It corresponds to any **connection machine** able to produce **rules** by progressive **adjustment** and **reinforcement** of a specific **behavior** resulting from repeated similar experiences. A good example is the "NetTalk", an electronic **network** aiming at modelling the **brain's neural network**, which is able to learn to pronounce more and more correctly English words. (J. BRIGGS and F.D. PEAT, 1989)

According to FRITZ, this is also the way people acquire their capacity for organized **behavior**.

→ **Algorithm (Back propagation) and Algorithm (Framing).**

0023

ACTUATOR²⁾

That **part** of the **regulator** which applies the corrective **action** on the **input**.

This term is used by some authors (for example J. MILSUM, 1968, p.41) in lieu of the more common "**effector**".

0024

ADAPTABILITY¹⁾

The capacity of a system (particularly a living one) to **accommodate** its **behavior** to a great **variety** of **situations**.

N. RASHEVSKY observes: "A very important characteristic of an **organismic set** is that, while its **elements** can potentially exhibit a number of **activities** necessary for the preservation of (its) **elements** and of the **set**, in general only a **subset** of the **set** of all potentially possible **activities** is exhibited" (1967, p.22).

RASHEVSKY shows by a biological example that many possible **adaptations** remain latent if not needed, i.e. become actualized only if some **environmental stimulus** awakens them.

Consequently: "The wider the **range** of potentially possible **activities** of an **element** of an **organismic set**, the greater is the **variety** of **environments** in which this **organismic set** can survive" (Ibid)

This is in accordance with ASHBY's concept that only (internal) **variety** can destroy external **variety**.

It is also obvious that, in many **organisms**, if not in all of them, the full **range** of adaptability is never revealed.

On the other hand, as expressed by RASHEVSKY: "The adaptability may be very great but it is always limited. No **set** of genes, no multicellular **organism**, and no society can survive in every conceivable **environment**" (Ibid).

In any case, as observed by E. LASZLO, systems of high **complexity** trade **stability** for richness in adaptability (1972).

0025

ADAPTABILITY (Hierarchically organized)¹⁾

In **complex systems** there are various **levels** of adaptability. In human **social systems** for example, local and specific **adaptations** can be made without **control** or **regulation** from more comprising **levels**, provided they remain within the established **tolerance limits**.

The advantages of such local **autonomies** are obvious, in terms of **resources** as well as **time availability**. It may even be a basic explanation of general **evolution** toward **complexity**, in accordance with SIMON's *Hora and Tempus* famous parable.

0026

ADAPTATION¹⁾

"The process of accomodating to **change**" (UNESCO - UNEP, 1983, p.5)

K. KRIPPENDORFF distinguishes two kinds of adaptation: "a) **Darwinian** adaptation... (through which) **organisms** change their internal **structure** when their **environment** makes existing **forms** no longer viable... e.g. ASHBY's **homeostat**.

"b) **Singerian** adaptation, after SINGER, who described how **organisms**, particularly man, change the nature of their **environment** so as to eliminate threats to, or prevent the destruction of their own internal **organization**" (1986, p.1)

For M. BUNGE: "The word "adaptation" is ambiguous, as it designates at least three different **concepts**, namely the following:

"A1. **Suitability** of a **subsystem**... to a **function** or high value of the **subsystem** for the entire **organism**;

"A2. **Adjustement** of the **organism** to its **environment**

"A3. **Fertility** of a biopopulation" (1979, p. 104)

The three concepts could be easily generalized to **sociosystems** or **technosystems**.

If adaptation is considered a **state**, then the **concept** is tautological: any **organism** demonstrates merely by its actual presence that it is adapted. On the contrary, it should not be here.

Adaptation is not possible without a device that reduces the cost of **regulation**, by modifying the **constraints** within which the system must function in such a way as to reduce the **amplitude** of its **fluctuations**.

As a **process**, adaptation has been described by D.T. CAMPBELL as successive "increases of fit of systems to **environment**" (1960, p.380), through selective retention of blind **variation**.

There could be more to it, since a continuous **evolution** of the **environment** takes place precisely through the permanent **changes** brought about by the various adapting systems within it.

N. BOTNARIUC pointed out that : "Adaptation is a **population** or species **level process** (i.e. supraindividual **level**) and it is different in nature from adequacy; it is the result of the historical action of natural **selection**" (1966, p.97).

0027

ADAPTATION and ADAPTABILITY^{1) - 3)}

1. Adaptation is a supposedly **stationary state** which implies a minimal **strain** between the system and its **environment**.

2. Adaptability is a permanent **process**, by which the system produces new adapted **states** whenever necessary.

W. KARGL explains it in the following way: "As **ontogenesis** must be understood as **drift** of structural **change** in **organisms** and in **environment**, there are no better or worse adaptation, but numerous possibilities for the **organisms'** relations with their **environment**" (1991, p.577).

Adaptation and adaptability are thus quite antinomic. A perfectly adapted system depends on the perfect **stability** of the **environment** to which it has adapted. If this adaptation is so absolute that it cannot be modified anymore, the system is in great danger of being destroyed, should its **environment** start to change. On the contrary, if it has maintained a potential for new adaptations (i.e. adaptability), it is generally able to respond successfully to new **changes** in its **environment**.

Adaptability "consumes" **redundancy** in order to produce successive adaptive **states**.

→ "**Order from noise principle**"

0028

ADAPTATION by step functions²⁾

L.von BERTALANFFY writes: "ASHBY's **model** for **adaptiveness** is, roughly that of **step functions** defining a system, that is, **functions** which, after a certain **critical value** is overstepped, jump into a new family of differential equations. This means that, having passed a **critical point** on its **trajectory**, the system starts off in a new way of **behavior**. Thus, by means of **step functions**, the system shows adaptive **behavior** by what the biologist would call **trial and error**: it tries different ways and **means**, and eventually settles down in a **field** where it does not come anymore in **conflict** with **critical values** of the **environment**" (1956, p.7).

ASHBY's **homeostat** is an electromagnetic **model** of this adaptation **mode**.

The adaptive capacity of any system thus depends on the existence, at least potentially, of this type of **step functions**. This **model** can be usefully compared with other concepts related to adaptation: **Requisite variety**, **Hypercycle**, **Organizational closure**, **Catastrophes**, **Bifurcation**, **Stability** in **topological** terms, etc...

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0029

ADAPTATION by ULTRASTABILITY¹⁾

A **complex system** will adapt to a given **environment** "by providing **second order feedbacks** that veto all **states of equilibrium**, except those that leave each essential **variable** within its proper **limits**".

Furthermore: "The **organism's** reacting **part** is itself divided into **subsystems** between which there is no direct **connection**. Each **subsystem** is assumed to have its own essential **variables** and **second order feedback**". (ASHBY, 1960, pp.208-209)

This concept is obviously akin to:

- 1.- Vendryes' **autonomy** by internal **regulations**
- 2.- Maturana and Varela's **organizational closure**
- 3.- Eigen and Schuster's **hypercycle**

An important remark by ASHBY is that "The **environment** is assumed to be **polystable**" (Ibid). Of course, no adaptation would be possible in a totally incoherent **environment**.

0030

ADAPTATION (Cumulative)³⁾

W.R. ASHBY demonstrates that: "...for the **accumulation** of adaptations to be possible, the system must not be fully **joined**" (1960, p.155)

This is a very important statement. It explains the reason why adaptation is, in some way **antagonistic** to **adaptability**. The **living system** needs a high degree of basic adaptation, which is obtained by **organizational closure** (related to a specific kind of **environment** and genetically shaped), which in turn limits **adaptability**. A very restrictive **organizational closure** implies that the system is strongly **joined**, as for example in the case of immunological rejection.

It could be also inferred that a high degree of **artificial intelligence** could be attained only by loosely **joined systems** of many **elements** and **subsystems**, which seems also to be the way the **brain** is organized.

0031

ADAPTATION (Noogenetic)⁴⁾

An adaptive ability proper to **human systems** able to understand specific adaptive needs and plan corresponding adaptive **modes**.

This notion has been derived from K. BOULDING: differentiation between biogenetic and noogenetic evolutionary **forms** (i.e. whose **evolution** is strongly influenced by their **brain**).

Noogenetic adaptation produces an acceleration of the **rhythm** of adaptation, which also explains the **evolutive acceleration** of mankind, that does not depend anymore merely on biological **change**. (F. MEYER, 1954, 1974)

0032

ADAPTATION (Obstacles to)¹⁾²⁾

Some of the most significant obstacles to adaptation are:

- Difficulty to evaluate former **performance** due to:
 - a) incomplete **data**
 - b) poor **criteria** for defining positive or negative **performance**
 - c) difficulty to distinguish between different **causes** of poor or good **performance** (causal multidimensionality implying **nonlinearity**)
 - d) difficulty to distinguish between short, medium and long **trends in performance** (a poor **performance** can be a near **random short-term fluctuation** or a **symptom** of a deep seated problem)
- Difficulty to discover **elements** or conditions that may lead to a better **performance**, including difficulty to select the most useful ones
- Difficulty to distinguish and overcome negative factors that induce poor **performance**
- Difficulty to arbitrate **trade-offs** between desired but contradictory **performances** (speed versus capacity in a **network** of roads, for ex.)
- Difficulty to avoid future local **optima** that may become dead ends

0033

ADAPTATION (Pre-)

→ **Pre-adaptation**

0034

ADAPTATION (Reciprocal)¹⁾

The **process** through which two or more systems or **populations** adapt to each other.

The systems must be compatible and more or less **complementary** in order to allow for a **process** of reciprocal adaptation.

For example, some plants, when attacked by a parasite, produce terpenes, which in turn attract parasites of the parasite. As a result, a global fluctuating **equilibrium** (even if frequently **chaotic**) tends to become established.

This **process** has been called "rivalrous adaptability" by H.G. BURGER, who sees it as a requirement for **complexity** (1967, p.211)

The **stability** of reciprocal adaptation can be altered among interacting **populations** if one of the partners starts to evolve. In such a case, reciprocal adaptation can still be maintained if the other partners succeed in turn in producing workable evolutive ways to respond to the **change**. We then have **co-evolution**.

0035

ADAPTATION (Second level)¹⁾

In case of necessity a **long-term** adaptation may replace a **short-term** one. G. BATESON gives the example of high altitude acclimatiza-

tion, as a human being will after some time, replace panting and heart acceleration by complex physiological **changes**. This 2nd level adaptation is more permanent than the 1st level superficial **changes**.

BATESON calls this type of adaptation "defence in depth" (1973, p.321).

This kind of adaptation is somehow **hierarchical**, as thus explained by W.T. POWERS: "... lower-order **reference levels** become the **means** by which higher-order systems act; the higher systems freely adjust the lower-order **reference-levels**, to create the lower-order **elements** of **perception** which will result in the specified higher-order **perception**. This creates a **hierarchy** of adaptation" (1976, p.84)

Ethological examples are also known and it would be interesting to try to find cultural ones.

0036

ADAPTATION (Serial)¹⁾

An adaptive **process** that follows a sequential **order**.

ASHBY, who introduced the notion, comments: "A great deal of **learning** occurs in this way. Mathematics, for instance, though too vast and intricate for one all-comprehending flash, can be mastered by stages. The stages have a natural articulation which must be respected if mastery is to be achieved" (1960, p.200).

ASHBY shows through other examples that serial adaptation is quite a general **pattern of behavior**.

0037

ADAPTATION PLAN (Genetic)²⁾

A naturally existing, or artificially installed plan for adaptation in a system..

The adaptive plan must respond to the following fundamental questions, as stated by J. HOLLAND:

"To what **parts** of the **environment** is the **organism** (system, **organization**) adapting?

How does the **environment** act upon the adapting **organism** ?

What **structures** are undergoing adaptation ?

What are the **mechanisms** of adaptation ?

What part of the history of its **interaction** with the **environment** does the **organism** **retain** ?

What **limits** are there to the **adaptive process** ?

How are the different hypotheses about **adaptive processes** to be compared ?

Moreover, as we attempt to answer these questions in different contexts, essentially the same obstacles to adaptation appear again and again. They appear with different names and

guises, but they have the same basic **structure**. For example, "**nonlinearity**", "false peak", and "**epistasis effect**" all designate versions of the same difficulty" (1992, p.2)

"False peak" is equivalent to "**local optimum**".

A general genetic adaptive plan may produce a number of different plans more precisely adapted to more specific conditions.

0038

ADAPTEDNESS^{1) - 3)}

Good **adaptation**.

H. PATTEE discussed this ambiguous concept in the following way: "How do we go about determining adaptedness? If a species is well-adapted, does this mean that **selection** pressures are low and we should not expect rapid evolutionary **change**? Or is evolutionary **creativity** an important component of **adaptation**?" (1972, p.33)

In other words, which one is better adapted: the amoeba, which has survived changeless for hundreds of millions of years by cloning itself, or man, a rather more recent, complex and "efficient" being, but whose future **survival** is anybody's guess?

In PATTEE's opinion, different criteria of adaptedness should be used at different **levels of complexity**.

0039

ADAPTIVE BEHAVIOR¹⁾

1. Any behavior that safeguards or enhances the **survival** ability of a **living system**.

2. "A form of behavior which maintains the essential **variables** within physiological **limits**". (W.R. ASHBY, 1960, p.58)

ASHBY starts with a sharp critique of the behavioristic concept of adaptive behavior: "The suggestion that an animal's behaviour is "adaptive" if the animal "responds correctly to a **stimulus**" may be rejected at once. First, it presupposes an **action** by an experimenter and therefore cannot be applied when the free-living **organism** and its **environment** affect each other reciprocally. Secondly, the definition provides no **meaning** for "correctly" unless it means "conforming to what the experimenter thinks the animal ought to do. Such a definition is useless".

Thereafter, he introduces the quoted definitions.

ASHBY's concept derives directly from Walter CANNON's **homeostasis** and indirectly from Claude BERNARD's "constancy of the inner **medium**".

Further along, ASHBY states "Adaptive behavior is equivalent to the behavior of a **stable** system (i.e. a system endowed with **dynamic stability**), the **region of stability** being the **region** of the **phase-space** in which all the es-

sential **variables** lie within their normal **limits**". (p.64). ASHBY proceeds by citing authors as diverse as STARLING, CANNON, PAVLOV and McDUGALL, who expressed much the same idea.

The individual adaptive behavior should be distinguished from the collective **adaptability** of a species, which is quite wider and in some cases at the expense of many individuals.

The concept should be extended to psychological and sociological behavior, even if these are very difficult to define in terms of measurable **variables**.

In more evolved **living systems**, adaptive behavior is obtained through **learning** or training. However, as stated by ASHBY: "The direct intervention of **consciousness** is evidently not necessary for adaptive **learning**" (1960, p.11)

One could argue that this is true only for **training**, if one considers training as non-conscious **learning**.

0040

ADAPTIVE CHANGE¹⁾

According to G. BATESON: "Whatever the system, adaptive change depends upon **feedback loops**, be it provided by natural **selection** or those of individual **reinforcement**. In all cases, then, there must be a **trial and error process** and a **mechanism of comparison**. But **trial and error** must always involve **error**, and **error** is always biologically and/or psychically expensive. It follows therefore that adaptive change must always be **hierarchical**.

"There is needed not only that first-order **change** which suits the immediate **environmental** (or psychological) demand, but also **second-order changes** which will reduce the amount of **trial and error** needed to achieve the first-order **change**" (1973, p.245)

One wonders how this could be translated to cultural adaptive **change**. (A good case for research would be the shaping of the European Union)

0041

ADAPTIVE PROCESS¹⁾

"The **process** whereby a (biological) system responds to its **environment** so as to adjust to the **constraints** of the **environment** and to take greater advantage of the environmental circumstances" (T.F.H. ALLEN & T.B. STARR, 1982, p.261)

Actually, the authors have defined "adaptation". in this way. However, "adaptation" would better describe some **state** at some instant. The global result of an adaptive **process** is a **sequence** of adaptive **states**, while the adaptive **process** mirrors the adaptive capacity of the system, i.e. its **adaptability**.

ALLEN & STARR coined their definition in relation to biological systems, but systems made of many **living systems**, especially human ones, are also adaptive.

0042

ADAPTIVE PROCESS (Statistical)²⁾

"A **process** in which the **chance** occurrence of appropriate or inappropriate **behavior** is positively or negatively **reinforced**, respectively" (A. H. KLOPF, 1972, p.59).

According to KLOPF: "Such a **mechanism** eventually produces a **network** that, to some degree, models the **organism** and the **environment**. As the **model** becomes increasingly refined, the statistical aspect of the adaptive **process** becomes less apparent and **behavior** appears more directed" (Ibid.).

Using KLOPF's terminology, as well as ASHBY's, one may say that the **heterostat** tends towards the **homeostat** when its **behavior** tends to **stability**. On the other hand, they stabilize because any system must become **autopoietic**: its **coherence** can be maintained only if, in some defined **environment**, some types of **behavior** are either impossible, prohibited, strongly **constrained** or, on the contrary highly favored.

The system goes on, constructing progressively its own **algorithm**, by a **trial and error process**. Besides, it constructs this **algorithm** in a specific way, because it does not start from scratch, but from some **archetype**, which allows only for a pre-defined **repertory** of admissible **variations**.

0043

ADAPTIVE SHIFT¹⁾

A **process** in a **population** through which individuals resistant to some destructive factor become gradually more numerous, while non-resistant individuals are eliminated.

This **process** had been observed already in the 19th century, for instance in a moth living on the bark of birches in England, adapting to the blackening of the colour of the bark due to industrial pollution and as a result of selection pressure exerted by predator birds.

The danger to produce similar **side-effects** by the use of insecticides or antibiotics, was signaled as early as 1953, but not heeded. Adaptive shifts have now produced the appearance of resistant **populations** of many insects and pathogens. The lesson has however not yet been learned, as shown for example by the dubious use of genetic engineering to create selective resistance to chemical killers in cultivated plants with the hope to selectively kill weeds, which supposedly could not acquire such resistance.

0044

ADAPTIVE SYSTEMS (Basic characters of)¹⁾

To begin with, as observed by L.A. ZADEH, "... all systems are adaptive, and the real question is what they are adaptive to and to what extent" (in G. KLIR, 1991, p.143). Indeed, a non-adaptive system could not survive at all.

KLIR observes, furthermore, that even a **goal-oriented system** must maintain its **goals** within a **range** allowing for its own **survival**, "which implies that the (very) **goal-seeking element** must be capable of **adaptation**" (1991, p.149)

It is also difficult to conceive an adaptive system that should not be endowed with at least a modicum of **anticipatory behavior**.

A. WILDEN establishes the following list of characteristics of adaptive systems, inspired by M.C. MARNEY and N.M. SMITH (1964):

1. Auto-differentiation or **growth**
2. Characteristic **response**: A **response** or a **set** of possible **responses** **constrained** by the limited **semiotic liberty** of the system. This **response** could be modified at the "**learning to learn level**" and also by **evolution**
3. **Selectivity**: The capacity of distinguishing **stimuli information** from **noise**, the **form** from the **background**.
4. **Learning**: Capacity of modifying the characteristic **responses**
5. **Homeostasis**: **Synchronic stability** within **limits**
6. **Homeorhesis**: **Diachronic stability**, of first **order** also within **limits**.
7. **Redundancy**: Protection of the system against **random perturbations** (implied in 5 and 6).
8. **Memory**: The sine qua non of **communication**, depending of the clues.
9. **Simulation**: Some form of **behavior**, mediated by **memory**, application, reduction, **semiotics**, **language**, including the capacity of **reproduction**.

"This enumeration is not supposed to be absolutely complete, nor to establish ordered priorities among the mentioned characteristics" (WILDEN, 1972, p.61)

It may be objected that **homeostasis**, as well as **homeorhesis**, is **diachronic**, if one admits that the first word is synonym of **dynamic stability**. The difference between **homeostasis** and **homeorhesis** is that, while **homeorhesis** characterizes the **growth** period of the system, **homeostasis** is proper to its maturity (specially in biological systems), when the system only maintains, without wide modifications, its **structures** and **functions** within more or less narrow and invariable **limits**.

As to **redundancy**, it only protects the system if it can be used to enhance its **variety** or at least to reveal it.

0045

ADAPTIVENESS¹⁾

"The ability of an individual or system to modify itself or its **environment**, when either has changed to the individual's or system's disadvantage, so as to regain at least some of its lost **efficiency**" (R.L. ACKOFF & F.E. EMERY 1972, p.124).

ACKOFF & EMERY write: "The definition of adaptive implies four types of **adaptation**:

- Other-other **adaptation**: an individual's or system's reacting or responding to an external **change** by modifying the **environment**;
- Other-self **adaptation**: an individual's or system's reacting or responding to an external **change** by modifying itself;
- Self-other **adaptation**: an individual's or system's reacting or responding to an internal **change** by modifying its **environment**;
- Self-self **adaptation**: an individual's or system's reacting or responding to an internal **change** by modifying itself" (Ibid)

0046

ADAPTIVENESS (Limited)^{1) - 2)}

It stands out of ASHBY demonstration that "...for the accumulation of **adaptations** to be possible, the **system** must not be fully **joined** (1960, p.155)" that any further **adaptation** tends to increase the degree of "jointness" of the system, or in other words to increase **constraints**. As the system's **variety**, even if considerable, is limited, there seems to be a progressive increase of the defined possible **states** and a reduction of the potential for defining new ones, i.e. of adaptiveness.

In ASHBY's words: "**Adaptation** (we would say "adaptiveness")...demands not only the **integration** of related **activities**, but the **independence** of unrelated **activities**" (p.157)

0047

ADDING JUNCTION²⁾

The spot where two **energy flows** of similar type add up. (adapted from H. ODUM - 1971, p.39)

0048

ADDITION²⁾

"The **relation** of the joining of **parts** so as to increase their number" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.33)

Only the **composite systems** seem to offer this extremely simple way of reunion and **growth**. Examples are the accumulation of grains of sand forming a dune under the action of wind, or the gathering of locusts changing from solitary to gregarious phase, or a reunion of many non-related people to attend some sport **event**.

0049

ADENOSINE TRIPHOSPHATE (ATP)¹⁾⁵⁾

A rich energy-producing nucleotide (J. ECCLES, 1977, p. 233)

ATP's formula is $C_{10}H_{16}N_5O_{13}P_3$ and is an **energy** source in many **metabolic** reactions in living beings

ATP acts as a neuro-transmissor. Its action can be affected by Adenosine triphosphatase which is "an enzyme splitting of phosphate from ATP and so producing **energy**" (Ibid)

→ **Chemotaxis**; *Dictyostelium discoideum*

0050

ADJUNCTION²⁾

"Kind of **organization** whose governing **relation** is **symmetrical independence**" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.36).

According to these authors, in this type of ordering: "**Parts** can survive their separation" (Ibid).

This corresponds to the case of **colonial systems**, or **colonies**. If, for some reason, the **links** between **elements** or **parts** become severed, each of them remains able to survive as an **autonomous** entity. Such is the case of the **elements** of a sponge, or the multiple clones in a **colony** of poplars, if the connecting roots are severed, or also in plants which propagate through rhizomes or stolons.

Starting from the adjunction mode of **organization** it is in principle possible to advance toward more **integration** or to return to **independence**.

0051

ADJUSTER²⁾

A system which is merely able to a limited degree to "hold its internal **variable** constant in spite of **changes** in the external **variable**".

G. BATESON, following C.L. PROSSER, proposes to distinguish **adjusters** and **regulators**, the latter ones being better able to maintain the **constancy** of their internal **medium** (Cf. Cl. BERNARD and P. VENDRYES).

BATESON gives the following examples: "... the homoiothermic animals are classified as **regulators** in regard to temperature while the poikiloothermic are **adjusters**. The same **dichotomy** can be applied to aquatic animals according to how they handle internal and external osmotic pressure" (1973, p.331)

BATESON added to these two categories the **extraregulators** (like man), which are able, up to a point, to control and modify their **environment**.

0052

ADJUSTMENT²⁾

"A systems-**environment interaction** or **process** by which the system responds to the changing requirements of its **environment**". (B BANATHY, 1973, p.85)

Adjustments, according to B. BANATHY "are **changes** that a system brings about in order to modify its **behavior, structure** and characteristics so that it can produce improved system **outputs** or **system states**" (Ibid.)

The capability for making adjustments is the general condition for **adaptability** in any system.

Speed is a crucial factor in adjustment. N RASHEVSKY states: "...whenever any system is displaced from its **equilibrium configuration**, it always takes a finite **time** to reach that **equilibrium** again" (1967, p.72).

If the need for new adjustments appears before the first one has been completed, complex **effects** related to the **time lag** mechanism may introduce new **phenomena**, as for example **hysteresis**.

0053

ADJUSTOR²⁾

Device for potential **regulation** in a system built in such a way as to be able to take account of certain possible **variations** of the **environment** and to produce appropriate compensatory **behavior** of the system.

A. LOTKA introduced the idea in 1924 and constructed an experimental **model** in the guise of an artificial mechanical insect fitted with a pair of antennae which act as a spatial **sensor** at some distance (1956, p.341,382).

Such an artificial device throws light on the nature of adjustors in natural systems:

- The adjustor is *specific*. It is able to interpret some **data** of a certain **class**, as for example evaluate the **critical** distance away from some obstacle.
- It must be able, at least potentially, to use the **data** transmitted by **effectors** and **elaborators**.
- It must be able to carry out the needed comparisons between the captured **data** and the registered **norms** ... (for example maxima length, or maximum tolerable potential or weight)
- In view that its **action** aims at avoiding potential inadmissible **situations**, it evokes in our minds the illusion of intentionality.
- Its registered **norms** imply a **range** of possible futures, which gives us the illusion of (perfect) **predictability**.

One may conceive the need for adjustors of adjustors, for **coordination** of complex **behaviors**. Such a notion is very stimulating for the study of neuro-physiological **behavior**, as well as social **regulations** or **artificial organisms** "physiology" or "ethology".

The "timer" concept, introduced by Jessie MILLER is an important development of the adjustor's concept. (1990)

0054

ADVANTAGE (EQUAL) PRINCIPLE

→ **Boundary of equal advantage; Density (Optimal)**

0055

AFFILIATION¹⁾⁴⁾

F. ROBB resumes as follows G. AHRNE's concept of affiliation (in his critique of this author's book in Syst. Practice and Action Res.12(3), p. 312):

"People are related (in **organizations**) by "affiliation", which is usually compulsory in the cases of kinship and citizenship and which is usually entered into by **choice** in other cases (i.e. in enterprises and voluntary **organizations**) "Affiliation allows access to certain material **resources** accumulated by the **organization** and it entails the **performance** of some more or less well-defined obligations.

Almost all goods...are owned and controlled by **organizations**. Hence, if people want to have access to anything more than the most simple goods, they have to join **organizations**, and promise to come back again.

"To become an "affiliate", you have to be admitted, perhaps by passing some test, and to be recognized by others in the organization as having a unique **identity**: but only an identity in relation to the **organization**. You have to exchange a loss of some **autonomy** for access to the **organization's** collective **resources** and power, you have to promise to submit to surveillance, recorded **control**, and coercion, and you must return to the **organization**. But all affiliates are substitutable, no one is indispensable to the viable **organization**"

While in this description affiliates are human, members of human **organizations**, it is obvious that affiliation is a feature in different forms of all **elements** of all types of systems, from **cells** in the living being to ants in the anthill. It is in fact a basic feature of **sociality**.

→ **Immunity**

0056

AFFORDANCE¹⁾

The kinds of **behavior** the **environment** allows to a **living system**.

This concept is introduced by J.J. GIBSON (1986, p.36-37). A typical example is as follows: "A **path** affords pedestrian locomotion from one place to another, between the terrain features that prevent locomotion... (as) obstacles, barriers, water margins, and brinks (the edges of cliffs)" (p.36).

Affordance defines thus the **tolerance limits** of **constraints**. According to GIBSON, the concept derives from K. LEWIN's *Aufforderungscharakter* (i.e. invitation character). Affordance is obviously related to the **competence** of the user of the **environment**, who has to *learn* which **behavior** is affordable in different circumstances.

0057

AFSCET¹⁾

Association Française de Science des Systèmes Cybernétiques, Cognitifs et Techniques

This french society organizes symposiums on a variety of scientific and social **issues** from a systemic or cybernetic viewpoint. Recent examples are: Integration du vivant au social (2003) and Evolution du vivant et du social (2002)

AFSCET also has specific interests groups, among them:

- Aspects systémiques du développement durable
- Intelligence artificielle et processus de décision
- Systémique et biologie
- Systémique et société

AFSCET publishes a journal: "Res-Systémica", which is sponsored by the Systems Science European Union. (<http://www.res-systemica.org>)

The web address of AFSCET is:
<http://www.afscet.asso.fr>

0058

AGEING¹⁾

Ageing could be understood as a **process** of **information** saturation in the system. As the system becomes more closely adapted, by the precise definition of evermore numerous internal **states** in **response** to external **noise** formerly assimilated, it seems to use up its **redundancy**. Thus, as it becomes better adapted, it also loses in a progressive way its potential for **adaptability** and its **thresholds** of **instability** become narrower, which implies a growing danger to cross one of them irreversibly and to destroy itself.

Ageing seems also related to **growth limits**. The system seems to become clogged with a growing number of **constrained interrelations** between **subsystems** and **elements**. It thus turns more rigid and less responsive to **disturbances** from its **environment**, until it reaches a **state of sclerosis**.

Altogether the system may become too voluminous, or overextended. In this case the **cost** of maintaining long and heavy **communication** lines becomes an additional burden.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Generally speaking, life is a **nonequilibrium process** submitted to the laws of **thermodynamics** and ageing is a disorganizing, or over-organizing **process** dominated by a growing difficulty to maintain a low internal **entropy**.

0059

AGENCY¹⁾³⁾

"The degree to which a person believes he or she can chose and act freely"(W. McWHINNEY, 1995, p. 5)

McWHINNEY writes: "People vary in the degrees to which they recognize **free will**, that is, on how much they can personally and collectively control **behavior** in their **environments**" (Ibid p. 4)

For a better appreciation of this notion, see "**Autonomy**" and more precisely P. VENDRYES's (1908-1989) views.(1956 and 1981)

0060

AGENT¹⁾

An active **element** in a multi-**elements system** or **network**.

J. ERCEAU and J. FERBER describe the following types of agents, at different **hierarchical levels** in the active multi-agents **system**:

- "**reactive agents**: these are at the lower **levels**. They merely dispose of a reduced **protocole** and **communication language** and ... their abilities rely only on a **stimulus/action rule**. The reactive agents **class** include various **levels**, according to their **group-forming** ability and capacity to produce global **behavior**;
- "**communicating agents**, which possess a complete **communication protocole**, but whose conversational and behavioral **parts** are **interdependent**;
- "**rational agents**, which possess precise abilities, beliefs and a partial **representation** of their **environment**, specially of the other agents within the system;
- "**intentional agents**, at the highest **level**, possessing explicit **goals**, specific plans which allow them to fulfill their **goals**, as well as the possibility to commit themselves to specific tasks, that they are obliged to carry out, or to contract other agents to execute certain **actions**". (1991, p.757-8)

This could be a stimulating **description** for a **model** of any society.

More recently, J. FERBER (1999) has given a much more precise definition of an agent: Agent is a virtual or physical entity which:

- 1) is capable of acting in an **environment**
- 2) can communicate directly with other agents
- 3) is driven by a set of tendencies (in the form of individual **objectives** or of a satisfaction/survival **function** which it tries to optimize)
- 4) possesses **resources** of its own
- 5) is capable to perceive its **environment** (but up to a limited extent)

6) has only a partial representation of this **environment** (and perhaps none at all)

7) possesses skills and can offer services

8) may be able to reproduce itself

9) whose **behavior** tends towards satisfying its **objectives**, taking account of the **resources** and skills available to it and depending on its **perception**, its **representation** and the **communication** it receives

"Having the properties 1-9) an agent can be considered as an "intelligent system"(Ibid)

From this description N. SAFFARPOUR (2000, p. 75) deduces the following characteristics of agents

- Agents are **autonomous**, i.e. have **control** over their own actions
- Agents contain some level of intelligence, from fixed **rule** to **learning engine** that allows them to adapt to **change** in the **environment**
- Agents don't only act reactively, but sometimes also proactively and don't simply act in **response** to **environment**, in other words agents are **goal oriented**
- Agents have social ability, that is they communicate with the user, the system and other agents as required
- Agents may also cooperate with other agents to carry out more complex tasks that those they themselves can handle
- Agents may move from one system to another to access remote recourse or even to meet other agents
- Agents are adaptive, that is change their **behavior** based on previous experience

All these specifications are quite significant in a general sense, even if some terms used may seem ambiguous (as f. ex. "intelligence", "move from one system to another")

→ **Adaptability; Artificial life; Autonomy; Behavior (Anticipatory); Intelligence (Distributed artificial); Stigmergy; Swarm**

0061

AGENT (Meta-)¹⁾⁴⁾

"An agent who is capable of some sort of **meta-level** reasoning about the multi-agent **community**". (M. PECHOUCEK et al., 2000, p. 659)

The authors state that the meta-agent neither controls the **community** nor serves as a **communication centre**". It is thus neither a **controller**, nor a "**black board**"

The authors distinguish two types of meta-agent's **activity**:

- static **observation**
- dynamic **observation**"

Through static **observation** the meta-agent obtains a "state of affairs" picture

By dynamic **observation**, it may predict for ex. an "approaching critical **overload** of an agent"(note: or possibly of the whole system)

On the other hand "from the point of view of the meta-agents impact on the **community** we distinguish two principal **roles**:

"- **Passive role**: the meta-agent does not influence the **community life-cycle**...it (merely) provides the user with the **information** on how the **community** evolves in **time**...The meta-agent playing a passive role does not have any means how to modify directly the multi-agent community.

"- **Active role**: the meta-agent affects directly some other-agents within the **community**. Here the meta-agent usually revises (by directly delivered **messages**) the local **knowledge** bases of the agents. The proper active role should be ensured by means of dynamic **observation**" (p. 659-60)

→ **Multi-agents system**

0062

AGGLUTINATION²⁾

Mode of **organization** governed by "**aseriality**, where **parts** have **intransitivity**, **connexity** and **symmetry**" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.36)

This is the kind of **organization** proper to **composite systems**, whose **elements** gather or separate from each other without any **order**, are in direct contact and whose relative positions may vary in an indifferent way. Such are the case for example of flights of gregarious locusts, or human crowds.

The existence of such systems is simply a result of the global statistical **behavior** of the **elements**. Individual movements are however closely conditioned by some general characteristics of the **environment** as for example the prevailing winds, the **circadian rhythms** or some ideological polarization.

0063

AGGREGATE²⁾

"A compound thing , the **components** of which are not coupled, linked, connected, or bounded" (M. BUNGE, 1979, p.4).

BUNGE gives as examples a celestial constellation, or a **random** sample of a biological **population**.

The only significative character of aggregates is a certain localization in **space** and permanence in **time**.

C. ZELLER constructed some **models** in order to establish the conditions of **stability** of aggregates (1967, p.53-55). This author states, for instance, that, in the case of geometric **elements** in a plane, **stability** "... is reached when six neighbours are gathered around a base **element**". (See: "**Hexagonal space filling**")

It depends, besides, on the shape of the **elements**, on the **initial conditions** and, probably on the nature of the substrate.

The **relations** among **elements** are thus not *absolutely random*. The aggregate, when submitted to certain variations of its **environment** may offer a degree of collective **behavior** which may even become repetitious and correspond to characterized **processes**, as for example **directional growth**.

The theory of **criticality** studies the **behavior** of such typical aggregates as snow or sand banks or the characteristics of aggregative **phenomena** as bush and forest fires, mud slides or stock market panics.

According to A. ANGYAL "Wholes cannot be compared to additive aggregations at all...

"In aggregates is is significant that the **parts** are added; in a system it is significant that the **parts** are arranged" (1969, p.26).

And, besides: "... aggregation and **whole** formation are **processes** of an entirely different **order**" (p.27)

It remains nevertheless true that aggregates seem in some cases to be the forerunner of **association** and **differentiation**.

According to V. KREMYANSKIY: "In **chaotic** aggregates, the **interconnections** between the **elements** are comparatively uniform, but they are particularly simple when a relative organizational simplicity typifies the **elements** themselves. The nature of the **elements** is not changed by entering or leaving the aggregate. Where there is a large number of **elements**, **changes** in the **chaotic whole** depend more on **changes** in many **elements** than on solitary or small **groups** of **elements**. The total of its internal **interconnections**, and hence the internal conditioning of the **changes**, bears a predominantly statistical or "probability" character". (1969, p.126-7)

Some authors use the term "**congeries**" (plural) as a substitute for aggregate.

0064

AGGREGATION 1 ¹⁾

A progressive **process** of **interconnections** between formerly unconnected **elements** or systems.

Aggregation is related to the existence of a **critical distance** between the **elements**. The **process** takes place when **crowding** becomes such as to hinder the fully independent **relation** of each **element** with its proper **environment**.

A famous example of aggregation – in **living systems** – is the life **cycle** of the slime mold *Dictyostelium discoideum*. The growing proximity of the individual amoebas (due to a combination of **population** explosive **growth** and the exhaustion of food) induces reciprocal **perception** of biochemical products and gregarious reactions leading to social **behavior**, in accordance with H. PATTEE's **statistical closure**. Aggregation thus seems to be a **process** basic for the shaping of social **living systems**.

One wonders if the massive intercommunication **process** presently in progress between human **groups** does not herald global mankind aggregation in the same way.

0065

AGGREGATION 2 ²⁾

The compression of a **set of data** into less numerous units which presents their common properties.

The most radical aggregation mode is statistics, a powerful **variety reductor**.

H. SIMON notes that, in many **complex systems**, analysis is much simplified by the fact that the influences on each **element** of all other **elements** are organized in a simple way. This is because the anonymous character of the specific **interactions** leads to a very important simplification, not only of the global system, but also of the **functions** which describe the **component** systems (1990, p.138).

→ (SIMON's Hora and Tempus parable)

While such a simplification is very useful, it also may be altogether sometimes questionable, because it may imply (and generally does) a loss of **information**. Furthermore, it is the *observer* who decides the **level** of aggregation, in accordance with his/her specific interest (and personal **blindspots**). This **level** can be for instance micro- or macrophysical, chemical, biological or sociological.

Another difficulty has been signaled by K. KRIPPENDORFF: "Aggregation leads to misleading indicators and theories whenever the whole collection exhibits an **organization** not expressed in a mere **summation**" (1986, p.1)

In complex systems, aggregation of **data** may occult relevant **interrelations**... or even introduce imaginary ones, when the "common" properties result merely from a mere unconscious and unwarranted hypothesis. These distortions may occur, for example, in the construction of complex **computer models**, needed in **systems dynamics**.

This problem turns worse if the aggregated **variables** do not any more correspond to observable **state variables**, as for instance in the global aggregate called "pollution". J. MARTINO observes: "... the effect of pollution on **population** actually occurs as effects of specific pollutants on specific individuals" (1979, p.17).

0066

AGGREGATION (DIFFUSION LIMITED)(DLA) ²⁾

A **fractal** aggregation type of **model** constructed on a computer, that starts with a single seed particle and grows to form a **cluster** by allowing tiny circular particles to attach themselves, one at a time (After I. STEWART, 1992, p.14).

STEWART explains: "Successive new particles move towards the **cluster** in a "random walk", a series of **random** motions in all directions often likened to the motion of a drunkard. Wherever the particles hit, they stuck" (Ibid).

Clusters thus obtained "... offer a "random fractal geometry"... difficult to characterise in analytic terms; that is no one has a way of predicting the **pattern** that will be generated, short of doing an experiment and observe the result... (However)... surprising regularities emerge from apparently unstructured DLA **clusters**" (Ibid).

Furthermore, the observed **fractal patterns** bear a great similarity with a number of natural **forms** as in electrodeposition of metals and in the **growth** of bacterial **colonies**. Some kind of **order**, related to **fractalization**, seems thus to emerge from **randomness**, and seems to govern the progressive occupation of **space** under partially undetermined conditions.

0067

AGIL imperatives ¹⁾

A mnemonic for remembering "the four imperatives that must be adequately fulfilled for a system by its **subsystems** if that system is to continue to exist" (M.C. JACKSON, 1992, p.46).

"The **meaning** of the terms that make up AGIL is as follows:

A. **Adaptation** – the system has to establish **relationships** between itself and its external **environment**

G. **Goal attainment** - **goals** have to be defined and **resources** mobilized and managed in pursuit of these **goals**

I. **Integration** – the system has to have a **means** of coordinating its efforts

L. **Latency** (or **pattern maintenance**) – the first three requisites for organizational **survival** have to be solved with the minimum of **strain** and **tension** by ensuring that organizational "actors" are motivated to act in the appropriate manner" (Ibid)

As mentioned by JACKSON, these four imperatives were originally stated by T. PARSONS and N.J. SMELSER.

0068

AGONOMETRY ^{1) - 2)}

"**Adaptability** through rivalry" (H.G. BURGER, 1967, p.209-22)

According to BURGER: "... all types of **evolution** are different in **structure** but similar in **process**. They consist of a rivalrous **polymorphism** that awaits **environmental change**. Up through the ethological **level** the **change** is **exogenous**, such as climatic. At the ethnic and intercultural **levels**, an additional type of **change** becomes available through **perception**" (p.209).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Polymorphism is equivalent to **variety**. As to rivalry, it should not necessarily bring about the elimination of the (presently) ill-fitted. They can remain in a minority position as a **variety store** until circumstances change.

BURGER applied his **concept** from biology to sociology and even **linguistics (polysemy)**. It never became widely recognized, possibly because of its "struggle for life" undertones, arguably more apparent than real.

0069

AGONISTICS³⁾

A general **model** of dialectical **antagonisms** in biological and **social systems**.

This concept has been proposed by the French physician E. BERNARD-WEIL (1975). It is related to **stresses** in systems due to **dissymetries** and maladjustments. The author uses the bow and the string as a **metaphor**. He studies numerous examples of such **antagonisms** and proposes a mathematical formalism. He acknowledges the old sources of the **concept**, as can be found in ANAXIMANDER, HERACLITES and the Chinese **concept** of YING and YANG.

The connexion with **symmetry-breaking** is also obvious.

0070

ALATORY (or random) PHENOMENON²⁾⁻³⁾

According to M. BELIS: "Aleatory phenomena present a subjective aspect related to the **observer** and an objective one, which corresponds with their own nature. The subjective aspect consists of the difficulty to know (by **observation** or by **measure**) the perturbing phenomena which exert some influence on the results of the **process**. The objective aspect is precisely the fact that the **process** can be influenced by infinitesimal variations of the **environmental** phenomena, i.e. that it is **unstable**. While perturbing phenomena generally also take place in **deterministic processes**, the **stability** of these latter makes them invulnerable to **perturbations**. A phenomenon is either **random** or not, independently of the presence of an **external observer**, but according to the **instability** or **stability** of the causal **connection** which determines it. As POINCARÉ did notice, the movement of the heavenly bodies is a **stable, deterministic phenomenon**, independently of the degree of any terrestrial **observers** ignorance, while dice throwing is aleatory because of the **instability** of the **causal connexion** which determines the results" (1938, p.66).

However, POINCARÉ himself has been the first to show that, even objectively, the movements of the heavenly bodies are not rigorously **deterministic**. He demonstrated the impossibility to find a perfectly exact solution to the

three bodies problem and set the first bases of the theory of **chaos** which is presently being developed (Understanding **chaos** as **randomness** within **deterministic limits**).

M. BELIS pursues nonetheless as follows: "However, after a long succession of experiences a **stability** of the results appears in cases in which the **unstable causal connections** are a structural make-up of a number of permanent causes".

This is precisely how most aleatory phenomena, **random** at **short term**, show nevertheless at long **term** an embedding global **determinism**, which figures basically a kind of statistical **limit to randomness**.

0071

ALERT CONTROL→ **Control (Alert)**

0072

ALGEDONIC LOOP²⁾

A positive or negative reward **feedback**.

Algedonic means: by pain or pleasure, i.e. implying punishment or reward.

Rewards can be quite various in kind. St. BEER cites as examples: teaching, bribing, the **epigenetic landscape** (1968, p.368). The **concept** appeared in psychology with PAVLOV and was (over) exploited by B. SKINNER.

According to BEER the algedonic loop "... interferes with the alleged **randomness** with which the **variety generator** pose solutions, as well as vetoing further attempts to pose the same unsatisfactory solution as before. It biases the throw of the dice" (p.368)

Further along BEER explains how this reward **feedback** allows very **complex systems** to produce in due time – notwithstanding the necessity of considering many interconnected conditions for **action** – "... a very ingenious and appropriate **response**" (p.395)... and how, if corrective **mechanisms** "were highly stable, their **response** to gross **perturbation** would be too sluggish and would call for huge **control energies**" (p.396).

The algedonic loop could probably be usefully mimicked in **Artificial Intelligence**

0073

ALGORITHM^{2) - 3)}

A step-by-step ordered and finite **set** of prescribed **operations** along an optimal **path**, whose use permits the solution of a specific **class** of problems.

Any algorithm implies **determinism**.

J.Z. YOUNG gives a definition related to computation: "A **program** by which a complicated calculation is reduced to a long series of simple ones" (adding: "that a digital computer can perform": see hereafter the comment on artificial – or natural - **neural networks**).(1978, p.289)

G. KLIR states: "The intuitive notion of an algorithm was formalized in several ways, including formalizations based on the concepts of **TURING machines**, **MARKOV** algorithms, and **recursive functions**, which were all proved to be equivalent" (1991, p.127)

An algorithm may be quite complex and contain a number of subordinated **routines** and instructions for their eventual use. However, the **TURING machine** is, at least in principle, a universal **representation** of all possible algorithms. The potential and global use of an algorithm is strictly limited to its **content**, which necessarily reflects an implicit and specific **representation** of its **field** of application.

GÖDEL's **incompleteness** concept is thus valid for any algorithm.

As to algorithms relations to natural or **artificial intelligence**, it can be argued that they are merely acquired properties of **brains** or computers. In the latter's case, they must be introduced in the **machine** as a product of natural intelligence. It is now however conceivable that artificial **neural networks** could become able to **construct** complex algorithms by **learning**.

According to R.W. FULLER and P. PUTNAM, this is precisely what the nervous system does: "... (the) basic operation of the nervous system: establishing a relative **dominance** among the members of a **class** of competitive motor **acts**" (1967, p.103)

Knowledge itself seems to be stabilized through algorithms. R. FISCHER, quoting H.M. COLLINS, writes: "... the discovery is generally re-constructed as if it followed an algorithm, a narrative receipt, with the experience of **contingency, trial and error** written off as irrelevant "**side effects**" (1992, p.229).

According to the Russian psychologist L. VYGOTSKY, children use private speech (i.e. speak to themselves) as a self-narrative way to acquire new skills, until the moment they dominate it. (L. BERK – 1994, p.60)

This possibly explains why **knowledge acquisition** through teaching is so different from discovery and self-training, and sometimes quite stultifying.

0074

ALGORITHM (Back propagation)⁵⁾

A procedure to compute the **errors** resulting of the **activity** (EA) **level** of a unit in a **neuronal** computer **net** (i.e. the difference between the actual and the desired **output**), and to correct accordingly the corresponding **error weights** (EW).

In a neuron which processes **signals** (= **activities**) each **input** is multiplied by a number called the weight. The sum of the weights, as computed by the neuron, determines the **output** of the neuron through an **input-output function**.

If the **output** differs from the desired **activity**, i.e. when there is an **error** in **activity** (EA), this **error** is calculated as "the square of the difference between the actual and the desired **activities**", as stated by G. HINTON.

The weights are then modified in order to reduce the **error** in **activity**.

The back-propagation algorithm – invented around 1974 by P. WERBOS – is thus basically a **feedback process**.

In HINTON's words, "The back-propagation algorithm is easiest to understand if all the units in the **network** are **linear**... For **nonlinear** units, the back-propagation algorithm includes an extra step. Before back-propagating, the EA must be converted into the EI, the **rate** at which the **error** changes as the total **input** received by a unit is changed". (1992, p.106)

This corrective mechanism is iterative (see below)

0075

ALGORITHM (Framing)²⁾

The concept of framing algorithm surges from the successive applications of internal **rules** (for instance of **positional values**) to incoming **inputs**. Progressive betterment of their **assimilation processes** tend to stabilize into more closely defined **channels**.

M. MARUYAMA proposed to apply this **model** to embryology: "Since **information** is generated by the **interaction** between various **parts** of the embryo, it is not necessary for each **part** of the embryo to contain **information** regarding the body **part** it is destined to become. It partly receives the **information** from other **parts** ... and from its **relationships** to them" (1963, p.238).

This looks like a case of progressive **organizational closure**.

0076

ALGORITHM (Genetic)²⁾

"A **stochastic**, **iterative**, evolutionary general purpose search **strategy** based on the principles of **population** genetics and natural **selection**".

The genetic algorithm was proposed by J.W. HOLLAND (1975, 1992) as a way to the **simulation** of adaptive **population** systems. He generalized it as "genetic **operators**" **models** that can be used for the study of **optimization** problems and more recently for **automata learning**.

The genetic algorithm, not being narrowly **deterministic**, does not lead to just a simple **solution**, but on the contrary opens the way for a progressive and adaptive search for better solutions in evolving conditions.

HOLLAND distinguishes the following transforming operations: crossing-over, inversion, **mutation**, **selection**.

These **operations** are found in nature. But they are frequent in any system wherein numerous **agents** act collectively as a **population** engaged in an adaptive search.

A. AGAPIE writes: "Genetic algorithms (GAS) are robust probabilistic algorithms for optimization, relying strongly on **parallel computation**. their power comes from multi-point exploiting of the searching **space**" (2000, p. 35)

→ **Neural networks; Parallel distributed processing**

0077

ALGORITHM (Iterative refinement)⁵⁾

An algorithm which progressively produce better answers when iterated.

As "the **backpropagation algorithm** is just a steepest descent approach without any line search... it inherits the well known disadvantages of the **gradient method**: The **convergence** depends strongly on the starting **values** of the **parameters**. The direction of the local steepest descent is often far different from the overall direction where the minimum lies" and... "The algorithm... normally either **overshoots** the minimum (with the risk of **oscillations**) or – if the **gradient** is small – there is hardly any progress at all" (TRONCALE, 1985, p.449).

This difficulty is alleviated by the introduction of iterative refinement algorithms.

Such algorithms are constructed from a **set** of **rules** whose **operation** is **interactive** and not rigorously **preprogrammed**.

It is however open to debate if such a kind of mental device really fits within the concept of algorithm.

0078

ALGORITHMIC COMPLEXITY²⁾⁵⁾

The degree of **variety** in a chain of **data**.

For example, the chain 001011101101001 is much more complex than 1010101010...., which can be reduced to a **program** "Repeat n times 10".

0079

ALGORITHMIC COMPRESSION^{2) - 3)}

"(Any) formulation which can explicate or reproduce an extensive **pattern** of **data** from only a few succinct **rules**" (D. Mc NEIL, 1993 b, p.3)

Mc NEIL sees science itself as a **process** of algorithmic compression: "The pursuit of science... results in **categorizations**, **classifications**, **taxonomies**, and formula which describe the **associations** and the **structures** attributed to **phenomena**. An ideal of a science is to design algorithmic compressions to describe its subject matter" (Ibid)

The paramount example is the search for the "theory of everything". **Systemics** and **cybernetics** also try to discover algorithmic compressions, in the guise of **transdisciplinary concepts** and **models**.

0080

ALGORITHMIC INCOMPRESSIBILITY^{3) - 5)}

The impossibility to reduce a string of **data** to a simpler algorithm that would permit to retrieve them.

G. CHAITIN demonstrated that: "A completely **random** string of digits cannot be reduced to a shorter **program** at all". On the contrary: "... a regular string of 1s and 0s describing some **data** such as 0101010101... which continues for 1000 digits can be encapsulated in a shorter instruction "repeat 01 500 times" (1990, p.45-46)

Chaitin related this finding to TURING's **un-computability theorem** and showed that: "the **halting** probability is arithmetically **random**" (Ibid)

According to CHAITIN, TURING's "... result that the **halting** probability is **random** corresponds to TURING's assertion that the **halting problem** is undecidable"

From another viewpoint, St. KAUFFMAN states: "One measure of the **complexity** of an algorithm is the minimal **program** length which yields the desired **output**. The more minimal an algorithm is, the less **redundancy** it contains. Consequently, minor modification of minimal **programs** grossly alter the **output** of the algorithm. In contrast, minor alterations of highly **redundant** algorithms modify **output** only slightly" (1993, p.231). Thus, algorithmic compression may make an algorithm's **behavior** more uncertain.

0081

ALGORITHMIZATION BY SELECTION¹⁾⁵⁾

The **process** of **reinforcement** of some neuronal groups in the **brain** and elimination of other groups.

This theory, proposed by G. EDELMAN (1987) as a "theory of neuronal groups selection", seeks to explain the progressive **organization** of the **brain** as a result of the acquired **dominance** of some groups of **neurons** which become frequently reactivated through re-entries of **signal** impulses.

This **process** leads to the **stabilization** of some specific perceptive and ordering **patterns**, which become the basis for future evaluations of new **perceptions**. It seems to correspond to the progressive construction of **reference frames**.

→ **Experimental frames; learning rule**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0082

ALGORITHMS (Genetic)²⁾

"A family of **methods** that search for optimal solutions of difficult **problems**" (P. DENNING, 1992, p.12)

The concept of genetic algorithm was originally developed by J. HOLLAND as a computer **modelization** of biological **evolution**.

P. DENNING writes: "Genetic search algorithms cross-breed trial solutions and allow only the **"fittest"** solutions (those accorded the highest **value**) to survive after several generations" (Ibid) They are thus, up to a point, self-perfectible, and a possible **model** for an evolutionary **mechanism**.

The genetic algorithm avoids at least partly what is possibly the most serious inconvenient of algorithms: their premature **stabilization** at a **sub-optimization level**. This result is obtained by a kind of "cooperative **competition**" by recombination or cross-over between different "candidate" solutions and the introduction during the progressive constructive **process** of a very slight **variability** ("mutations") within each elemental **situation**.

Kenneth DE JONG quoted by P. DENNING, states that "a mutation probability on the order of 0,001 per **bit** is enough to prevent the search from locking into a local **optimum**".

In this way, premature **sub-optimal** solutions are avoided and a global **optimum** can be more easily reached.

C. EMMECHE resumes as follows the **procedure** of a genetic algorithm:

"1. Select **program** pairs on the basis of how well they have solved the **task** (one can thereby measure **fitness**). The better the solution, the greater the **chance** to be selected.

"2. Apply the genetic **operator** (cross-over, eventually combined with a small **chance** of **mutation**) to the selected **program** pairs in order to create offsprings in the next generation.

"3. Replace the least successful **programs** with the offspring created in step two, and repeat the **process**" (1994, p.115)

He adds: "Empirical investigations indicate that this crossing-over scheme operates specially well on problems that programmers otherwise regard as genuinely difficult.

The genetic algorithms are able to exploit the **population** experience in an optimal manner" (p.116)

→ **Parallel distributed processing**

0083

ALGORITHMS' LIMITS³⁾

In relation to algorithms' possibilities to mimic intelligence, P. DENNING states: "For me, the existence of multiple, incomplete interpretations actually supports PENROSE's basic claims about mental as opposed to computational **processes**. Like a system of logic, an interpretation cannot include all **phenomena**. Our

powers of conscious **observation** give us a capacity to step outside a particular interpretation and devise extensions or alternatives. Thus **consciousness** itself cannot be captured by any fixed **description** or interpretation. How then can **consciousness** be captured by an algorithm, which is by its very nature a fixed interpretation? This question applies also to algorithms that are apparently designed to shift their interpretations, because the **rules** for shifting constitute an interpretation themselves" (1990, p.102).

Include a "theory of everything:" within an algorithm seems to be a hopeless task. However the **brain** itself becomes partly **constrained**, by **learning** specific skills and **behaviors**. Could this not be viewed as a partial algorithmization? As to the **rules**, should they not be left "open", as for example behavioral **rules** in a **network** in lieu of interpretation **rules** within an algorithm?

For an exhaustive debate on this topic see R. PENROSE's "The Emperor's new mind" (1989)

0084

ALGORITHMS THAT CANNOT BE CONSTRUED³⁾

N. KASKOV "demonstrated that the following mass problems could not be solved in the framework of the **General System Theory**:

- to construe an algorithm allowing to find all the **elements** of a given system
- to construe an algorithm allowing to find all the **connections** of a given system
- to construe an algorithm allowing to determine the **structure** of a given system
- to construe an algorithm allowing to determine all the **functions** realized by any given system (even if one knows its **elements**, **connections** and **structures**)" (BLAUBERG, SADOVSKY & YUDIN, 1977, p.205)

Any **complex system** seems to contain a power for innovative and unpredictable **variations**, due probably to its relatively open character.

0085

ALL OR NONE TRANSITION¹⁾

A type of **transition** that admits only two opposite **states**.

These **transitions** are congruent with the **all or nothing principle**. They admit no **fuzziness**. Examples are: open vs. closed; outside vs. inside; positive vs. negative; one vs. zero.

→ (**flip-flop device**)

0086

ALL OR NOTHING PRINCIPLE¹⁾

Stimulus-response situation in which **response** is unavoidably total, or nought.

J.C. TABARY notes: "Particularly at the sensorial neurons **level**, a univocal **response** appears when sufficient number of membranous **receivers** are simultaneously stimulated.

"The **organism** is informed about the **receivers stationary state**, but not on the peculiar characteristics of the stimulating **event** itself. Considering that, very generally, there are only two possible **states**: **information** is really restricted to one **bit** only". (1989, p.278)

0087

ALLEE EFFECTS

→ **Undercrowding**

0088

ALLELOPATHIC¹⁾⁴⁾

"Character of a substance which has inhibitory effects on other **organisms**" (P. COLINVAUX, 1973, p. 605)

In a more general and somewhat **metaphoric** meaning, it seems that some **informations**, **values** or **norms** exert inhibitory effects in societies.

→ **Inhibition**

0089

ALLOGENESIS²⁾⁵⁾

A **phase** of adaptive **radiation** in an **evolutionary process**. (W. SCHWEMMLER, 1991, p.152)

0090

ALLOMETRY²⁾

Fixed or variable proportional **relationship** between different **parts** in one or various systems

It is already an old idea to try to compare the modifications of the proportions of various **parts** of the same system through **time** or the proportions of a corresponding **part** of various systems at the same moment of their **growth**.

The 19th century French paleontologist Georges CUVIER used the concept as a "principle of **correlation** between **parts**": "Any organized being forms a **whole**, a unified and **closed system**, whose **parts** correspond all to each other and converge towards the same definitive **action**... None of these **parts** may change without **changes** in the others too, and as a result, each separately considered shows and gives all the others" (CUVIER, 1812, as quoted by Stephen J. GOULD - 1983)

This idea has been reworked and considerably extended, specially in relation to **evolution** by d'Arcy W. THOMPSON (1916 - re-ed.1952) and later on by J. HUXLEY, alone (1945) and in collaboration with E.C.R. REEVE (1972, and in HUXLEY, 1945, p.267)

0091

ALLOMETRY (Principle of)²⁾

"As the **growth** of any particular **structure** proceeds, in the absence of **change** in the **pattern** of the **structure** itself, volumes will grow eight times as fast and surfaces will grow four times as fast as **linear** dimensions" (K. BOULDING, 1972, p.87)

As observed by L.von BERTALANFFY: "The simple relationship of allometric increase applies to many **growth phenomena** in biology (**morphology**, **biochemistry**, **physiology**, **evolution**)" (1962, p.12)

Commenting on this principle, K. BOULDING expresses that it also applies to social **organizations**, in a more subtle way: "... **organizations** eventually limit their own **growth** simply by the sheer difficulty in getting **communication** from the "surface" of the **organization**, where it is in contact with its **environment**, into the **decisions**-makers who are not in direct contact with the **environment**" (1972, *Ibid*)

In this case, it is mainly a problem of **time lags**. However, even if **communication** is accelerated through technical devices, **strain** and **saturation** may well occur, by **overload**, or **chaos** may seep in.

0092

ALLONOMY²⁾

The property of a system characterized by **input-output relations** (LE PEUTREC, 1994, p.1553)

S. LE PEUTREC and M. COURANT explain: "Such a system needs an internal representation of its **environment**. The **environment** controls the internal functioning of the system" (*Ibid*)

This is the case of common **regulators**: While they endow some larger system with some **autonomy**, they themselves are not autonomous.

Allonomy is a property somehow complementary to **autopoiesis**. According to P. VENDRYES, **autonomy** is not possible without internal **regulators**, registering external **perturbations** and reacting to them as kind of **buffers** allowing for the permanence of the systems **identity** and **processes**.

Or: "Allonomy is a logics of correspondence, while **autonomy** is a logics of **coherence**". (*Ibid*, p. 1554). There is a kind of **symbiosis** between two **antagonistic behaviors**.

0093

ALLOPOIESIS^{1) - 2)}

The production by a **network** of interrelated **component-producing processes** of a system, which does not however becomes able to thereafter reproduce its **components** and **processes**. (Adapted after M. ZELNY and N. PIERRE, 1976, p.150)

According to these authors: "... the actual realization of such systems is determined by **processes** which do not enter into their (own) **organization**. They are non-**autonomous**, since their realization and longevity as unities are not related to their **operation**" (*Ibid*)

In another paper, ZELNY states: "Allopoietic systems are organizationally open. They produce something different from themselves" (1977, p.14)

Allopoiesis is of course the opposite of **autopoiesis**, which implies **organizational closure** and thus, **self-reproduction**.

ZELNY and PIERRE give as examples of allopoietic systems "crystals, formal **hierarchies** and concentration camps" (*Ibid*)

Complex **artifacts** as for example cars or planes or machine-tools seem still more allopoietic: they are not self-created and are controlled from outside.

However, if the allopoietic system is to be really a system, it must at the same time be **autopoietic** in order to maintain its **identity** and **coherence**. This would be possible if we admit that the **boundaries** or other **subsystems** transform **inputs** into internally fitting **elements**, i.e. integrates them into the **organizational closure cycle**, while producing **outputs** by an inverse **transformation**. Some of J.G. MILLER 20 critical **subsystems** do just that.

According to H. MATURANA, an **observer** may treat an autopoietic system as if it were allopoietic by considering the perturbing **agent** as an **input** and the modifications undergone by the **organism** (which maintain its **autopoiesis**) as the **output** (1974, p.425). This is, for example, the way of traditional psychiatry.

However, this treatment does not reveal the **autopoietic organization** of the system.

0094

ALLOSTASIS¹⁾

The conservation of dynamic **stability** during a **process of change** in a system

Any system or **subsystem** is normally able to cope with a more or less wide **range of inputs**.

As expressed by ASHBY, a system counts with a defined **variety** which allows it to adapt to specific variations in its **environment**.

The french biologist P. VENDRYES, in turn, explained that the system is able to maintain itself within **limits** of adaptive **fluctuations** if it counts with sufficient **reserves** (or **resources**) disposable for use.

Allostasis has thus a qualitative and a quantitative aspect.

However if variety and/or resources are insufficient and tend to be exhausted, non adequately compensated **input perturbations** create **stress** in the system.

If stress becomes excessive or persists for long **time**, the system may undergo severe damage and, in extreme cases, be destroyed.

→ **Break down; Collapse; Criticality; Equilibrium; General adaptation syndrome; Heterostasis; Homeostasis; Regulation; Synergetics**

0095

ALPHABET²⁾

"An ordered **set** of characters which can be combined to form the ensembles, words or expressions of a **language** or to represent **data**" (K. KRIPPENDORFF, 1986, p.2)

Many kinds of alphabets are in existence: the very numerous different alphabets of written and spoken **languages**, the conventional combinations based on a **binary code**, and even the 20 basic amino-acids of DNA and RNA chains.

To express that an alphabet is an "ordered **set**" means that it corresponds to differentiated **symbols** and that its use is **constrained** by defined **rules**. For example "chtch" is a sound and a letter in Russian and the combinations "mb", "ng", or "nz" are admitted in Kiswahili, but none of these are normally used in English.

Any alphabet is thus a specific system.

In a sense, any **taxonomy** that uses a kind of ordering base of **classification** to be applied on the combinations of a limited number of well defined **elements**, could be considered an alphabet.

0096

ALTER

→ **Contingency (Mutual)**

0097

ALTRUISTIC UTILITARIANISM

→ **Utilitarianism (Altruistic)**

0098

AMBIENT (= UMWELT)¹⁾

"The **set** of the small number of characteristics to which an **organism** reacts". (L.von BERTALANFFY, 1962, p.73)

This concept was introduced and developed by J.von UEXKÜLL and G. KRISZAT (1934, 1979)

BERTALANFFY explains the concept as follows: "...any **organism**, so to speak, cuts out from the multiplicity of surrounding **objects** a small number of characteristics to which it reacts and whose ensemble forms its ambient" (p. 73)

The **perceived** ambient is only a reduced **part** of the **environment**, which does not mean of course that non-perceived environmental conditions could not affect the **organism**. Exam-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

ples would be the effects on human beings of ultra-violet or X-rays, which were completely unknown to our forefathers and that we are still unable to perceive directly.

BERTALANFFY also notes that: "...the organizational and functional plan of a living being determines what can become '**stimulus**' and 'characteristic' to which the **organism** responds with a certain **reaction**" (Ibid).

von UEXKÜLL has given numerous and sometimes startling examples of ambients corresponding to various animals, showing how unexpected and even outlandish they can look for us.

This ambient concept, transferred to human **organizations**, may help to explain many failures of environmental **perception in management**.

0099

AMBIGUITY³⁾

The condition resulting from a **sign** or **signal** bearing different possible **meanings** for an **observer**.

Ambiguity results of the lack of a clearly selective **context** to allow for the clarification of **meaning**. It is a **perceptive situation**, related to **languages** (spoken, written, pictural or other). E. BUCHBERGER observes that: "Multiple **semantic meanings** cannot generally been solved in an isolated way and lead to considerable difficulties" (1987, p.57)

Any **receiver** possesses his/her **repertory** of interpretations of **signals**, but this **repertory** has been formerly learned.

If, for example, we look at the well known young woman, old woman picture, only one of both possible perceptive **gestalt** intervenes for us at any moment, exclusive of the other. The potential for ambiguity is in the picture, but it reveals itself only through the shifting glance of the **observer**.

According to A. RAPOPORT: "Even mathematical statements, which most people consider to be absolutely exact, and therefore either absolutely true or absolutely false, have a certain penumbra of ambiguity as they are usually stated. This ambiguity is less characteristic of mathematical statements than of others, but it is there nevertheless because certain qualifications are likely to be tacitly assumed in every statement. It would simply take too long to make a statement irreproachably unambiguous" (1967, p.292)

This problem is obviously related to the need to **recurrently** resort to **metalevels** for **distinction** or **validation** (**GÖDEL's incompleteness theorem**)

0100

AMPLIFICATION²⁾

"A **process** whereby a small **cause** has a large **effect**" (W.T. POWERS, 1995)

Amplification is "achieved by drawing on the **stores of energy** and bringing them to bear on the creation of narrowly focused **effects** in the **environment**..."

This possibility "...arises from the fact that **organisms** can draw on internal power supplies which are independent of the **energy** contained in **disturbances**" (Ibid.)

This is the same condition that leads to systems **autonomy** in the sense of P. VENDRYES (1908-1989)

0101

AMPLIFICATION AND STABILITY¹⁾

Amplification, if not compensated by for example a **negative feedback**, leads the **function** and the system towards an **instability threshold** and either a **runaway catastrophe**, or a **process of dissipative structuration**.

H. ODUM puts it this way: "In effect, a system is stable when the amplification factor of the **feedback loop** equals the potential **energy** losses along the **circuit**". (1971, p.181)

0102

AMPLIFIER²⁾

Any device suited to increase an **input signal**.

Amplifiers are generally incorporated within a **feedback device**. M.D. RUBIN even describes the **feedback** as "a unilateral power amplifier, with a fraction of the **output** of the amplifier subtracted from or added to the **input** of the amplifier" (1968, p.9)

H. ODUM describes a "constant **gain** amplifier", within an **energy network** in which: "...the amount of **energy** supplied from the upper **flow** is that necessary to increase the force expressed by the system by a constant factor, called the **gain**" (1983, p.39)

0103

AMPLITUDE²⁾

The maximum departure of an oscillating motion from its **time** -average **value** (T.F.H. ALLEN & T.B. STARR 1982, p.262)

0104

ANABOLISM¹⁾

The **process** of absorption and **assimilation** of specific **inputs** by a **living system**

The anabolic process includes the following phases:

- **Ingestion** or **transduction**: the translation of material, energetic or informative **inputs** from the **environment** into the system through its **boundary**.

- **Internal transfer**: the internal **translation** from the absorbed **inputs** to the **subsystems** that should use them.

- **Conversion**: the transformation of an **input** by a specific **subsystem** to make it fit for the use of the system. In the case of **information inputs**, the conversion **process** is called "**decoding**".

- **Production** or **association**: For material or energetic **inputs**, the synthesis of specific **components** of the system, out of the converted **inputs**. For **information**, the first stage of the **learning process**.

For the respective roles of the concerned **subsystems**, see J. MILLER's 20 **critical subsystems**.

The elimination of products by a **living system** is called "**catabolism**", while "**metabolism**" is the generic term for the complete **process** of absorption, **transformation** and elimination of **matter**, **energy** and **information**.

In a more or less analogic sense, higher **level living systems** (enterprises, **groups**, **organizations**, **communities**, etc...) all anabolize specific **inputs**.

0105

ANAGENESIS²⁾

"The step-wise **evolution** of the **dynamics** of **self-organization** itself, bringing into play new **levels** of systems with their appropriate **self-organization dynamics**" (E. JANTSCH, 1982, p.345).

JANTSCH, who introduced the **concept**, stated: "In microevolution, anagenesis arises from **endosymbiosis** of dynamic (or **ontogenic**) sequences of **structures**; in macroevolution from the **coevolution** of phylogenetic sequences of systems. It may be interpreted as self-transcendence in **space-time**" (Ibid).

This is the **evolution** of evolution **modes**. Anagenesis is probably to be connected with **emergence** of new **levels** of **complexity** through **dissipative structuration**.

This **process** also seems related to the appearance of higher **levels** of **sociality** (**cells** as societies of molecules, living beings as societies of **cells**, beehives as societies of bees, human societies) that produce *new types of individuals on a higher complexity level*.

The subject is very complex. JANTSCH's paper provides an interesting figure that makes it easier to understand.

0106

ANALOG PROCEDURE⁵⁾

According to J.von NEUMANN: "In an analog **machine** each number is represented by a suitable physical quantity, whose **value**, measured in some pre-assigned unit, is equal to the number in question" (1958, p.3).

The machine must be equipped with devices enabling it to operate suitable mathematical **transformations** on these quantities.

0107

ANALOGICAL or DIGITAL ²⁾ - 5)

Two different **methodologies** used in **simulation**.

Analogical **simulation** is based on **similarities** and uses mechanical, hydraulical or electrical **models** whose functional properties are sufficiently **similar** (i.e. **homomorphic**) to those of the **concrete system**. Reduced **models** of harbours, or scale **models** of **artifacts** are examples.

Digital **simulation** uses numerical analytical **models** that can be translated to **programs** adequate to be run on a digital computer.

0108

ANALOGUES ²⁾

"...systems which are physically different but dynamically equivalent" (R. ROSEN, 1972, p.56)

According to ROSEN: "... dynamical or functional properties can be studied essentially independently of specifics of physicochemical **structure**, while **fractionation**, or other **reductionist** techniques, are bound up with these specifics in an essential way" (Ibid)

0109

ANALOGY ³⁾

"A resemblance between the **relations** among things (rather than between the things themselves) (Adapted from J.W. SUTHERLAND, 1973, p.122)

K. KRIPPENDORFF states: "In the theory of **models**, an analogy between two systems is explained by one simpler system that **models** both, but by different **homomorphisms**" (1986, p.3) An analogy is thus a **limiting** conceptual **constraint**.

According to J.W. SUTHERLAND: "... the analogy is in the first and last instance a conceptual device designed to call attention to **isomorphisms**, and to engine the attempt to induce **causality** specific to a **phenomenon** by imposing a general **causality**" (p.123)

The first aspect does not seem objectionable. However, the second one could easily lead to dangerously sweeping generalizations by "embracing creeds" (POPPER, quoted by SUTHERLAND - p.117)

Further on, SUTHERLAND adds: "...analogies are properly used... as **masks** with which an a priori **chaotic situation** can be at least partially ordered, subsequent to empirical **validation** of the **causality** proposed by the **mask**. Grand operational principles then, in the hands of the serious scientist, simply become systemic, encompassing **heuristics** whose utility lies not in their reification but in their perspective". (p.127)

0110

ANALOGY (Abuse of) ³⁾

A number of serious abuses of analogy have been registered in the use of **cybernetic** and **systemic models**, generally by neophytes carried away by their initial enthusiasm for a **methodology** which seemed to them to promise grand solutions to intractable problems.

Obvious examples are the illusion of rigid **control** by **regulators** of mechanist types in biological, economic and social systems; some "**catastrophic**" (no pun!) **models of behavior** in **social systems** and, more recently some misunderstandings about **chaotic models**.

A subtler case can be found in J. FORRESTER's "**World Dynamics**" as it was applied in the famous first **Club of Rome** Report. This outstanding piece of work suffers from an excessive rigidity due to the presence of numerous cybernetic **loops** whose **simultaneity in action** is never considered (C. FRANÇOIS, 1977). In J.W. SUTHERLAND words: "... both human beings and the collectivities they form would have to be considered "dynamic, **goal seeking systems** that change their **environment** and are not merely passive victims of it" (F. GEORGE, 1970, p.21) and, if this is the case, then "the simple servoanalogy breaks down, as does our ability to collapse all relevant **behavioral** determinants into a simple, fabricative **state-variable**" (1973, p.124)

In any case K. BOULDING expressed: "If analogy is dangerous and leads to the development of untrue systems, the remedy is not to throw it overboard altogether, for there are **situations** in which no other **method** of systems development is open to use. The remedy for false analogy is not *no* analogy, but *true* analogy. This involves the development of a critique of analogy and a theory of **simulation**... It is ... one of the principal concerns of the **general systems** enterprise" (1974, p.36)

0111

ANALOGY-BUILDING ³⁾

As an attempt to transfer **similarities** from a **phenomenon** to another one, analogies imply some aspects that should be consciously assumed.

According to J.W. SUTHERLAND: "... analogy-building is an extension of assumptivism (note: see: **Assumptive Analysis, Reductionism**)... But the fundamental difference between assumptivism and analogy-building is that, in the latter case, we are imposing an entire **system of relations** rather than single **parametric values** or **sets** of predicates (cum first premises)" (1973, p.123)

St. BEER showed that the **process** of analogy building, or "scientific analogizing" consists in connecting conceptual **homomorphic models** of two or more **situations** (1968, p.111)

Using the example of the controversy around the **validity** of the analogy between **computers** and **brain** ("The **brain** is a **computer**" **metaphor**), A. RAPOPORT observes; "The controversy is obscured by clashing philosophical convictions.... The answer... is not to be found in what a **brain** and a **computer** "are" (such questions are vestiges of pre-scientific metaphysics), rather in what **brains** and **computers** do" (1966, p. 9)

We should add: and in which way they are doing it, as the **brain** seems to be working, at least partly, in a **simultaneous** manner, as a **network**, while the computer, at least the **digital** one, is basically sequential.

Ironically, analogy-building, in search of **homomorphisms** or **isomorphisms**, ends up in some cases as just a more refined **reductionism**. Systemists and cyberneticians should be aware of this !

0112

ANALYSIS ³⁾

"The separation of an intellectual or substantial **whole** into constituents for individual study" (The American Heritage Dictionary)

One of the most severe and persistent **semantic** muddle is the careless use of the term "analysis", even by systemists.

When a system is "analyzed", most or all of the **nonlinear interrelations** among its **parts** are unwittingly severed. As jokingly stated by J.L. LEMOIGNE, cutting a chicken into slices like a sausage does not yield an intelligible **representation** of the chicken. (1990)... and it should be quite more difficult to do.

Worse still, many people are not even aware of this problem. And different **observers** may "slice the chicken" in different ways, none very faithful to the original.

Analysis is perfect on its own (studying the **components** and at most their **linear relations**), but, as it generally leads to cutting the more complex **interrelations** between **interacting parts**, it is never a satisfactory substitute for the systemic global view, which is also indispensable for the study of **complex systems**.

Ideally, analysis should always be conjugated with **synthesis**, i.e. the synthetic view of the **whole**. Moreover this should also be a back and forth **movement**: analysis is useful and makes sense only in relation to the synthetic view and synthesis without a good **knowledge** of the interacting **parts** does not make much sense because it offers merely empty generalities that do not offer tools for action

0113

ANALYSIS (Functional) ²⁾

The functional analysis of a system includes:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

- an identification as precise as possible of the distinct **functions** of the system and their **interactions** or interferences
- in this way potential disfunctions and **risks** can be identified and, as a result, possible risks can be discovered and assessed. This can be done by "hazards and operability studies"; "analysis of possible failures of **components**"; "**critical effects** study"; causes and consequences diagrams"; "**failures trees**"; and others.

Statistical analysis is one of the main tools in this kind of analysis, as well as **Petri nets** and **Markovian processes models**.

→ **Cindynics**

0114

ANALYSIS (Sensitivity)

→ **Sensitivity**

0115

ANALYSIS SITUS ²⁾

"The study of those properties of **space** which are independent of shape or **size**

Analysis situs or situational geometry is practically a synonym for **topology** and was first used in this sense by H. POINCARÉ. It is concerned with the properties of **forms, contiguity, connections...** conserved through continuous deformations, stretching or contraction, but exclusive of tearing or folding.

0116

ANAMORPHOSIS ¹⁾

Trend toward an increasing **complexity**

This concept, introduced by WOLTERECK (1940), "has been indicated as a primary characteristic of the living, as opposed to inanimate nature ... and was often used as a **vitalistic** argument" (L.von BERTALANFFY, 1969, p.79)

In BERTALANFFY's opinion organizational laws exist at all **levels** in the universe. To search for them is one of the basic goals of **General Systems research**.

In fact, it seems evermore well confirmed (see for example Carsten BRESCH, 1977) that this same tendency is – or was – already active at the micro-physical **level** and that it is linked to the very general **phenomenon** of **structuring dissipation** researched by **thermodynamics of irreversible systems**.

Note: Another (unrelated) meaning of this term is: "A mode of distortion of an **image** such as it can be viewed only from a special angle or with the help of some instrument".

These optical deformations were used by the Milanese painter ARCIMBOLDO (1527-1593)

0117

ANARCHY ¹⁾

On this concept, FLOOD states: "Anarchy itself suggests **disorder** and lack of government; however the argument is not one of **entropy**, but as follows. Anarchy can cause such **strains** on a system, including **positive feedback**, that the system itself may go through a **transition**. In many cases anarchic **behavior** is a **catalyst** of a system **transition**, not from a **state** to another (within a predetermined **state space**, one to one **mapping** of the **state variables**), but rather from one nature to another. That is, some essential qualities are replaced by another **set** of essential qualities" (1991, p.188)

FLOOD does not elaborate much as to the causes of anarchy. There seem to exist basically two:

- Weakening of the **control** of the system upon its **parts**;
- **Overload** of **inputs** from the **environment**, basically excess of **energy** or **information** inflow, which produces local or general unresponsiveness or confusion by **saturation** of **communication channels**.

FLOOD states that: "The system's **label** however, may well remain the same: France was still France after the revolution" (p.181). True enough about the "**label**". But what about the deep **identity** of the "France" system? This is a good example of how difficult it is to apply even systemic concepts to socio-cultural **situations**. **Metaphorically**, one could speak of destructive anarchy, as for example in cancer, and constructive anarchy as in the case of ebullient **elements** breaking down some established **structures** and producing, as a result, some more efficient or encompassing global **organization**.

Besides, anarchy as a concept whose systemic **meaning** is still ill defined, should be clearly distinguished from **chaos**.

0118

ANASTOMOTIC NET ^{2) - 5)}

A **model** of **neuronal net** "in which each neuron listens to many and speaks to many" (W. McCULLOCH, 1974, p.14)

This definition corresponds to a **model** created by S. WINOGRAD and J.D. COWAN in McCULLOCH's laboratory.

These authors used such **nets**: "... in such a way as to incorporate the **redundant error-correcting codes** used in **coding** for **noisy communication channels** into the logical **functions** computed by each neuron in the **net**. The probability logic which results from their construction is **functionally redundant**, there are many more possible **functions** stored in the **net** than in our own anastomotic **nets**, and it is this **redundancy** which is used to obtain reliable computation. Given the assumption that the **rate** at which neurons malfunction is not

tied to the number of **inputs** playing on each one, the WINOGRAD – COWAN construction is in a one-to-one correspondance with that of SHANNON's which led to the **noisy channel coding** theorem and the existence of a **channel capacity**. On this basis there is an **analogous** computational capacity for reliable computers made of unreliable **components**" (Ibid)

In view of the recent developments in **neuronal nets** applications to **robotics** and **connection machines**, and their possible use for the study of **sociality**, this was indeed, in the fifties, inspired work.

0119

ANASTROPHE ¹⁾

Sudden appearance of some new **entity**.

This neologism has been seldom used. It is obviously the opposite of **catastrophe**. According to the catalan systemic historian P. VOLTES BOU, it has been introduced by C. RENFREW (Pers. comm.)

→ **Dissipation; Emergence; Thermodynamics; Zero-System**

0120

ANDRAGOLGY ¹⁾³⁾⁴⁾

The discipline that studies human **action**. Andragology is a creation of Gerard de ZEEUW and has been developed by him in Holland at the University of Amsterdam, as well as in conferences organized by the **Systeem Groep Nederland**; and in the journal *Systemica* of which he was editor in chief. Martha VAHL, a close collaborator of de Zeeuw, writes "Andragology... combines interests both practical (adult **education**, social helping, support through the built **environment**) and theoretical (the acquisition of supportive **knowledge**). In terms of the breadth of this definition, andragology, as a field, remains more or less unique to the Netherlands" (2002, p. 101)

This reference to the Journal "Systems Research and Behavioral Science" is a fundamental one about de Zeeuw and his collaborators work, being a Festschrift in his honor.

The same issue also offers a listing of de Zeeuw's publications compiled by M. Vahl and, generally, an abundant bibliography of the field.

→ **Conversation; Facilitation; Perspectivism**

0121

ANIMAT ¹⁾⁵⁾

An artificial **organism** whose **structures** and **processes** are as similar as possible to an animal ones.

The problem is however in the way an animat acquires such **structures** and **processes**.

There are three possible **models** of animats (at least!)

- animats can be made to learn **behaviors**.

This can be done endowing them with a **neural network**, thus making them adaptive

in a range of experimental situations through a **set** of interacting **rules** organized as to cope with external **changes** that may have an impact on the animat

- animats can be made evolutive. Again this can be obtained through an appropriate neural network and a set of rules. But the need for **evolution** can be installed by introducing a measure of **randomness** in the **rules**.

However, none of these animats models seems to tackle all the aspects of modelling animal **behavior**, specially "intelligent" beings.

E. VACCARI and M. D'AMATO write: "**Cognitive systems** are composed of multiple **sub-systems** which are simultaneously active and interacting. Their cognitive **behaviors** are pervaded by both continuities and discreteness and their kind of **structures** emerge over time. Further **cognitive processes** operate over many **time scales** and **events** at different **time scales** interact" (2000, p. 173)

In short, a good animal model should never become an **homeostat** in the sense of ASHBY.

Or, even the existence of **constraints** cannot totally prescribe all the modalities of **change**, and still less, stop **change** altogether.

Already in the 18th century LEIBNIZ (1646-1716) stated that any **change** in one **element** in an entity is conducing to modifications of all the other **elements**. Such a **process** takes necessarily place at multiple **levels**, in different ways, at variable **time scales**, and can thus be modellized only in a conjectural and imperfect way, be it for an animal, or an animat.

0122

ANIMORG ¹⁾

"A type of self-adaptive system that has the properties of complex **organization** in **dynamic equilibrium**, **regulated behavior**, and the ability to change, grow and reproduce"

This term, introduced in 1940 by R. GERARD, corresponds more or less to J. MILLER's "**living system**", but did not met with wide acceptance. (1956, p.158; 1974, p.121)

As a subclass of animorgs, GERARD distinguished "**epiorganisms**", i.e. **colonies** or societies made of individuals. (1956, p.158)

0123

ANISOCHRONICITY

→ Isochronous

0124

ANISOTROPY ²⁾

Character of any entity whose properties vary in line with different directions.

Any system is more or less anisotropic, generally very much so. Anisotropy is closely related to **structure** formation and maintenance, and reflects **disymmetries** resulting from **symmetry-breaking**.

0125

ANTAGONISM PRINCIPLE ²⁾

"Every system results from two antagonistic forces mutually binded" (S.LE PEUTREC & M. COURANT, 1994, p. 1550)

The principle was originally proposed in France by S. LUPASCO (who constructed a "logic of contradiction" – 1947): "It is antagonism, i.e. the coexistence of forces that attract o repel each other, or **conflict** with this attraction, that constitutes the fundamental mechanism, sine qua non of the physico-chemical **objects**, with more or less strong domination of some of them over the others... It is the nucleus where the antagonistic forces become most strongly equilibrated that constitutes the most resistant system, the one... most difficult to disintegrate" (1972, p.100)

Under this somewhat philosophical guise, it is easy to recognize C. LAVILLE's, or K. DE GREENE's, or D. Mc NEIL's views about **inter-acting fields**, or **vortexes**, or **toroids**, or H. SABELLI's theory of **processes**, all of which are basically **dynamic**.

LUPASCO, significantly, used the words "attract" and "attraction", long before **attractors** became a pass-word in so many systemic **models**.

In systems, we may observe the antagonism principle, for instance in **environment-system** antagonism, or inside of a system, the construction-destruction antagonism.

According to LUPASCO, the principle is rooted in a reflexive combination of the 2nd Principle of **thermodynamics**, that prescribes the increase of **entropy**, and PAULI's **exclusion principle**. LUPASCO gives as examples the **development** of an embryo, or the shaping of a hurricane; still another important research on the subject has been d'ARCY W. THOMPSON's on "Growth and Form" (1916)

LUPASCO also stated that "the antagonism principle appears...as the formation principle of any system, as well as the bedrock of systems logics" (1982)

0126

ANTHROPIC PRINCIPLE ³⁾

J.D. BARROW and F.J. TIPPLER formulated this principle (1986). According to them, the nature of the physical world must necessarily be such that the perceptive and intelligent **observer's** existence be possible.

A **universe** without witnesses would of course be a different **universe**... or would it "exist", i.e. is existence possible without self-**consciousness** (even of a **part** observing the **whole** – or at least a larger fragment of the **whole**)?

It is difficult to evaluate the possible systemic **meanings** of these recollections from PLATO and BERKELEY. Whiffs of **solipsism** are floating around!

A more acceptable view of the Anthropic Principle would be that the **coherence** of multiple characteristics of the universe as we know it (microphysic and macrophysic constants, **space-time** characteristics, gravitation, etc.) merely implies that our own existence as conscious **observers** (after a very long evolutive **process**!) became possible, or even normal.

But this kind of extraordinary stretched cosmical **tautology** does not lead to any new and significant rational **development**. It may be more useful for theology than for science. (WALD, 1994, p. 123-31)

0127

ANTHROPOCENTRISM ¹⁾³⁾

The mental attitude and worldview that tends to interpret **facts** as significant only or merely in relation to man or mankind.

Of course, it would be probably impossible to do otherwise. However, as the self-understanding of specific people depends of the historical (or transient) circumstances, the anthropocentric view should be carefully and permanently scrutinized. Indeed even the most abstract **concepts** and **models**, as well as the supposedly "objective" **observation** remain necessarily products of the human senses and mental organization.

From the Ptolomeic cosmology to the so-called **anthropic principle**, we should all be always ready to recant from our own imaginations and illusions. **Conversation**, reciprocal critique and Popperian **falsifiability** are tools that should be put to more frequent use.

→ **Culturocentrism**

0128

ANTHROPOMORPHISM ¹⁾⁴⁾

The attribution of human characteristics, **behavior** or motivations to animals, physical **events** or imaginary beings (good or evil spirits, gods).

Considering its universality, anthropomorphism could be, according to J.Z. YOUNG (1978, p.289), a clue to an inherited **brain program**.

0129

ANTIBIOSIS ⁵⁾

An antagonistic relation between two types of **living systems**.

When two species are in such a **relation**, one species may eliminate the other. A variety of antibiosis is allopathy, where a species produces some toxic substance which impedes other species to establish or maintain themselves.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

0130

ANTICHAOS²⁾

A **process** through which "some very disordered systems spontaneously "crystallize" into a high degree of **order**" (After St. KAUFFMAN – 1991, p.64)

According to KAUFFMAN: "Computer **models** suggest that certain **complex systems** tend toward **self-organization**" (Ibid). The subject is closely related to the **behavior** of **composite systems** and their **self-organized criticality** (developed by P. BAK et al. in 1988; 1989; 1991).

It is not however the true antithesis of **chaos**, since **chaos** does not generally disorganize **complex systems**: it only makes the prediction of their **behavior** quite difficult, or downright impossible.

0131

ANTICIPATORY BEHAVIOR→ **Behavior (Anticipatory)**

0132

ANTICIPATORY SYSTEM¹⁾²⁾⁴⁾

A system able to define its own **goals**, or at least able to behave in order to tend in a permanent way to maintain itself in the future.

Human beings are more or less conscious of their **goals** and in many cases able to define and describe them. In other living beings the **goals** remain implicit and probably totally unconscious.

The study of anticipatory systems is quite difficult. B. EKDAHL writes: "Anticipatory systems are a result of **evolution** and the characteristic of them is that they consist both of **description** (genotype) and **interpretation** (phenotype). Many such systems are not conscious of their own interpretations and can be regarded as having only a built-in theory and no **language** in which its interpretations is described. Such systems show an algorithmic **behavior** and can be simulated on a **computer**."

"Systems which can also make a (**semantic**) **model** and moreover have a possibility to reason about this **model** cannot be reduced to computation since in no other language its **interpretation process** can be described than in the **language** itself.

"As a consequence, model-based anticipatory systems cannot completely be described by mathematical means but have to be **holistically** considered in order to give a reasonable **explanation** of their **behavior**. The way to look upon a system as a mathematical **structure** is not applicable in such cases" (2000, p. 13)

0133

ANTISYNCHRONY²⁾

The condition of two **oscillators** which are half a **cycle** out of **phase** with each other.

J. COLLINS and I. STEWART write: "The anti-synchronous motion has its own **symmetry**: the **oscillation pattern** is unchanged if the two **oscillators** are interchanged and their respective **phase** shifted by half a **cycle**"

Furthermore: "Coupled **networks** of three or more **oscillators** have more complicated **oscillation patterns** that just **synchrony** and anti-synchrony and some of these **patterns** are highly **counter-intuitive**" (1994, p.39)

0134

ANTISYSTEMIC WAYS¹⁾

Linear thinking is still widely practiced and leads to the illusion that a specific **issue** of problem can be isolated from **context** or **environment** and "solved" through some specific intervention, without any **side effects**. In this way a double problem appears:

1) the issue is artificially simplified and, as a result, misunderstood

(J. WARFIELD's **underconceptualization**)

2) **side effects** do indeed appear, and in some cases introduce new problems that may even be worse than those whose solution was sought.

Some are very dramatic, as for example:

- the Aral Sea disaster due to an ill-conceived river harnessing and an irrigation program that took no account of the possible effects on the **environment** of the whole region.
- the growing resistance of all kinds of pests to chemical insecticides, with for ex. the appearance of "super-mosquitoes" able again to propagate various illnesses that were thought to be controlled (Malaria, yellow fever, etc...)
- the growing resistance of pathogens to antibiotics and chemical medicines (Tuberculosis, malaria, hospital infections)

This does not mean that new ways to manage these **issues** (and many others) should not anymore be researched and used. It means that we need to become better chessplayers with nature and, specifically, that we should abandon our narrow views neatly characterized for ex. by the well known motto "**et ceteris paribus**", because, of course the conditions are never twice absolutely the same; or the illusions that any **event** has only one **cause** and produces only one **effect**, or yet that **predictability** is always perfectly and completely possible.

The **systemic approach** is becoming a full need in the complex world that we pretend to manage.

0135

APOMORPHY^{2) – 3)}

The appearance of a new characteristic, derived from a former one, in a **group** of living **organisms**, leading to the recognition of one and only one new **group**.

The concept of apomorphy is basic to the **taxonomy** of living **organisms** known as **cladism**. A particular group of apomorphic characters is what defines a clade.

0136

APOPTOSIS¹⁾⁵⁾

The **process** of **self-destruction** of the **cells** in the living **organism**.

Apoptosis is a very general **process**, active even at the embryological **level**, where it seems to be important for the progressive construction of the definitive **form** of the living being.

Every biological **element** or individual appears to include some **timer** device. The ways of apoptosis are becoming better known, but its deeper cause or causes remain obscure.

Its relation to **autopoiesis** as well as to **ageing** should also be researched more thoroughly.

This biological **process** discovered quite recently seems to imply a more general systemic **meaning**. It could mean that the need for the system to self-reproduce at its **level** of **complexity** corresponds necessarily to a longer **life time dimension** which is out of reach of its **elements**. This would be more generally an expanding **time dimension of complexity**

Human societies, for example, considerably supersede the living **limits** of their individual **components**, whose **ageing** seems to be commanded by some biological clock, i.e. a **timer**.

(For more on biological **apoptosis**, see "Science", Special issue, 281, nr.5381, 1998).

0137

APPEARANCES³⁾

G. BATESON observes: "Always the **process** of **representation** will filter out the *Ding an sich* – i.e the **object** in itself, so that the mental world is only **maps** of **maps** of **maps**, ad infinitum. All '**phenomena**' are literally 'appearances'" (1967, p.429)

The same view was developed as early as 1933 by A. KORZYBSKI in "Science and Sanity" → "**Structural differential**"

0138

APPRECIATIVE SYSTEM³⁾

"The interconnected **set** of largely tacit standards of judgement by which we both order and value our experience" (G. VICKERS, 1973, p.122).

According to VICKERS: "... the **components** of **human systems** – active individuals attributing **meaning** to their **situation** – make it impossible to study such systems using the **methodology** of natural sciences. The only way to understand **decision making** in **human**

systems is to understand the different appreciative systems that the **decision makers** bring to bear on a **problem**" (M.C. JACKSON, 1992, p.135)

And... "It follows, according to VICKERS, that if **human systems** are to achieve **stability** and **effectiveness**, then the appreciative systems of their participants need to be sufficiently shared to allow mutual expectations to be met. **Human systems** depend upon shared **understandings** and shared cultures" (Ibid)

In each culture, specific **values** and **norms**, transmitted through successive generations by imprinting, **learning**, teaching and training produce the equivalent of **organizational closure** in biological systems.

This is reflected in the so-called "Culture of the enterprise", the French "Esprit de corps", the Spanish "Espíritu de la colmena", the German "Gleichschaltung" and many other similar expressions related to cultural or ideological unifying (and dividing) appreciative mental and psychological frameworks.

→ **Semantic reaction**

0139

APPROACH ¹⁾²⁾

"An internally coherent and theoretically grounded collection of **models**, **methodologies**, **methods**, and **tools** used to learn about the world and to act in it" (K. BAUSCH-Glossary of terms- personal communication)

BAUSCH adds: "It is a flexible and creative way of engaging in a disciplinary **inquiry**" "However the **cybernetic** and systemic "tools" are mostly **transdisciplinary** because they are in fact "meta-tools" i.e. they can be applied in a similar way in many disciplines."

As an example **feedback** as a tool (or a **model**, for that) is a very general **mechanism** that can be recognized and used in all **nonlinear situations**, wherein a cyclical **loop** exist in the form **cause-effect-cause**.

0140

APPROACH (Analytic versus Systemic) ¹⁾⁻³⁾

The cutting edge of the systemic approach is thus stated by M. BUNGE: "A systemic approach to any subject boils down to abiding by the principle that every **object** is either a system or a **component** of a system. The methodological consequence is obvious: Nothing can profitably be studied in isolation" (1993, p.210).

J.de ROSNAY explains as follows the differences between the two approaches: "The analytic and systemic approaches are **complementary more than opposed**. However they are not reducible to each other. The analytic approach aims at reducing a system to its most simple constitutive **elements**, in order to study them in detail and understand the types of **interactions** which exist among them" (1975, p.109)

A good example is the study of the **components** of water and the way they associate: H²O is one bivalent O associated to two monovalent H, due to complementarity of electronic shells.

"Next, one modifies one **variable** at once to try to deduce general laws permitting the **prediction** of the systems properties in very different conditions. In order to be able to obtain such **predictions**, the laws of **additivity** of elemental properties must be valid. This is the case with **homogeneous systems**, i.e. those whose **elements** are similar and present weak reciprocal **interactions**. In this case, statistical laws can be applied and produce an **understanding** of the mass, i.e. of **inorganized complexity**" (Ibid)

In this dictionary, "inorganized complex systems" are named "**composite systems**" and their **behavior** is considered under the heading "**Criticality**". "The **additive** laws of elementary properties are obviously not anymore valid in the case of highly **complex systems**, made of a very great diversity of **elements**, linked by strong **interactions**. Such systems must be tackled with new **methods**, such as those of the **systems approach**. Their **goal** is to consider a system as a **whole**, with its proper **complexity** and **dynamics**. By the use of **simulation**, for example, it becomes possible to "animate" the system (i.e. its **model**) and to observe in real **time** the **effects** of the various types of **interactions** between the **elements**" (Ibid) This is done by FORRESTER's **Systems dynamics**, which is a powerful tool, but has also its weaknesses, for example about the real possibility to modelize **simultaneity** of **effects**.

"The study of its **behavior** in **time** leads to the determination of **rules** for **action**, whose aims are the modification of the system or the conception of new ones. Better than a point by point **description** of the characteristics of both approaches, it seems more useful to oppose them in a (comparative) table, not starting... a debate about their respective advantages or drawbacks" (Ibid) see table right column

"This table, useful because of its simplicity is however no more than a caricature of reality. This too dualistic **representation** locks thought up within an alternative, apparently difficult to avoid. Many other comparison points should be mentioned. However, while not exhaustive, the table is useful by defining two complementary approaches, of which one (the analytical one) has been favored in a quite disproportionately large way in our whole education" (1975, p.110)

Within the systemic approach itself, R. RODRIGUEZ DELGADO distinguishes three aspects, as follows:

"a) Static approach

Systems basic **structures**, **Components**, **Subsystems** and **elements**.

Analytic approach

Isolates: centered on **elements**

Observes the nature of **interactions**

Relies on precise details

Independence from time;

Phenomena are considered **reversible**

Modifies one variable at once

Validation of facts obtained experimental proof within a theoretical **frame**

Precise and detailed rigorous **models** difficult to use in **action** (for ex. econometric models)

Approach is efficient when **interactions** are weak

Leads to a disciplinary teaching (juxta-disciplinary)

Leads to a detailed **programming**

Produces a good **knowledge** of details; but ill defined **goals**

Systemic approach

Connects: centered on **interactions**

Observes the **effects** of **interactions**

Relies on global **perception**

Integrates duration and **irreversibility**

Modifies simultaneously groups of **variables**

Validation of facts obtained by comparing the way the **model** is working, with reality

Models are not enough as bases for **knowledge** but are **useful for decision and action** (for ex. The Club of Rome models)

Approach is efficient when the **interactions** are **non-linear** and strong

Leads to a **multi-disciplinary teaching** (Should lead to a **transdisciplinary** teaching)

Leads to an action aimed at **goals**

Leads to **knowledge** of **goals**, but ill defined details

Communication channels (System's Anatomy)

"b) Dynamic approach

System and **subsystems** functions. **Relationships** with **suprasystems** and **ecosystems**. Organic **cycles**. **Homeostasis** (System's Physiology)

"c) Dialectic approach

Reproduction of systems. Mutations. **Structural transformation**. **Selforganization**. (System's **ontogeny**) – Individual **transformation** and phylogeny – Apparition of **emergent species** or **models**

"Research into these complementary aspects open new possibilities to transform **environmental** conditions, human **organizations** and systemic **goals**, making easier the elimination of **constraints** and limitations" (1993b, p.32)

Of course, such positive aspects become possible because of a better previous **understanding** of these limitations and **constraints**, some of which may correspond to unavoidable and even in some cases, desirable (while misunderstood) conditions. Let us avoid any triumphalism.

0141

APPROACH (Hazards of the systemic) ³⁾

Joel de ROSNAY describes in the following way some distortions which could discredit the **systemic approach**:

"In order to better dismythify the **systemic approach** and allow it to maintain a **transdisciplinary** attitude and a training for the **control** of **complexity** and **interdependence**, should

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

we not even reject the very term of **systemic approach** or **method**? Everyone can learn to "stand back". Global vision is not a preserve of the great managers, the philosophers and the scientists. To learn the use of the **macroscope**, to apply the systemic **rules**, to build more rigorous mental **models** and even to be able to control the interplay of **interdependences** (can be done)".

"But we should not occult the hazards of a too systematic use of the **systemic approach**. A purely descriptive approach from the exclusive relational angle leads quickly to a useless collection of **models** of the different natural systems. The excessive generality of the systems concept may also be turned against it. Its fecundity may be destroyed by sterile **triviality**. All the same, the ill controlled use of **analogies**, **homologies** or **isomorphies** may lead to some complicated in spite of clarifying interpretations because they are based on superficial **similarities**, more than on basic principles and laws common to all systems. According to E. MORIN, "too much unification risks to lead to abusive simplifications, obsession and thought recipes".

"Once more we are threatened with the dogmatic danger if we draw the systemic approach back to an intransigent systemism or to a **reductionist** biologism. We are threatened by the seduction of **models** conceived as results of insight instead of starting points for research"

"One of the worse risks which threatens the **systemic approach** is to be tempted by a "unitary theory" (a "theory of everything"), an englobing **model** which should have a solution for everything and could predict everything. The use of the mathematical **language** – generalistic by its nature and vocation – may lead to a formalism apt to isolate the **systemic approach** instead of opening it to practice. The "General Systems Theory" barely escapes to this risk: at times it secludes itself within the **theory of graphs** languages, the **theory of sets**, the **theory of games**, the **theory of (quantitative) information**, at times it becomes no more than a **set** of descriptive approaches, many times quite illuminating, but devoid of practical applications.

"The operative **systemic approach** is one way to reach beyond these alternatives. It avoids the risky pitfalls of paralyzing **reductionism** and englobing systemism. It opens the way towards **knowledge transmission**, **action** and creation.

"About **knowledge transmission**, the **systemic approach** offers a conceptual **reference frame** which helps to organize **knowledge** in the course of its acquisition, reinforces its memorization and make its **transmission** easier.

"About **action** it enables to obtain **rules** to approach **complexity** and allows for the correct location and **hierarchization** of **elements**, basic for **decision making**.

"Finally about creation, the systemic approach catalyzes imagination, **creativity** and invention. It supports inventive thinking, while the analytic approach supports inquiring thinking. Systemic thinking should be tolerant and pragmatic, open to **metaphor**, **analogy** and **model**, formerly excluded from the "scientific method" and now rehabilitated. For the systemic approach, anything which ends partition of **knowledge** and releases imagination is welcome: it should be open, just as the systems it inquires" (1975, p.128-30)

0142

APPROACH (The Ten Commandments of the systemic)^{1) - 2)}

J.de Rosnay enumerates as follows the "10 Commandments of the Systemic Approach"

1. To keep **variety**
2. Not to open the **feedback loops** (i.e. not destroy the **regulators**)
3. To seek the **amplification** points
4. To establish **equilibria** through decentralization
5. To maintain **constraints**
6. To differentiate in order to improve **integration**
7. To evolve, by reaction to aggression
8. To prefer **objectives** instead of detailed **programming**
9. To know how to use **energy** (contained within **information**) for **management**
10. To respect **reaction delays**" (1975, p.122-127)

It is obviously possible to imagine other "commandments", less limited to human systems and, of course less operative, as for example:

- to define as precisely as possible the significant **environment** of the system
- to clearly define the main **objective** of the system and its subsidiary ones
- to find out the different **rhythms** of **activities** of the system and discover their interrelations
- to determine the degree of maturity of the growing system: just born, or emergent, in **steady state**, or in the **process** of **sclerosis**.

0143

A PRIORI (Kantian)³⁾

F. GONSETH discussed the validity of KANT's (1724-1804) a priori, when viewed as an absolute and unquestionable beginning for philosophy. He did not accept that "the debate is closed even before starting" when it is admitted that a priori are the "sine qua non of all

knowledge and judgements" as they set the very forms under which **experience** must unavoidably manifest to us" (1955a, p. 6)

In fact "compare a priori with the results of **experience** (of whatever kind) is simply compare them with themselves. Nothing can emerge of this, if not that they must be as they are"(Ibid)

Indeed, the a priori is established by the **observer** (supposedly being the infallible philosopher) within his own **frame of references** and we are led to the **autopoietic** critique of the ways we observe **reality** and of what **observation** amounts to in these bio-psychological terms.

In short, no a priori can establish an absolute starting block, being out of reach of falsifiable research of any kind.

0144

ARC⁵⁾

→ **Graph**

0145

ARCHETYPE¹⁾

The sum of interrelated characters, accumulated through **time** by former systems, which defines the basic **structures** and **functions** of a new system of the same kind.

Any archetype is a more or less abstract **model**, whose concept is Platonian in nature.

G. BATESON calls it a "**genotype**" and defines it as a "body of **memories**", as he refers himself basically to biological systems.(1973, p.287)

Nobody has ever given a definitive and rigorous explanation about the way archetypes become established. As to BATESON's "body of **memories**", F. DAVID PEAT connects in a hypothetical way Jungian psychoanalytical archetypes with the **hierarchic structure** of the **brain** which is "...often pictured as containing a series of evolutionary **levels** beginning with its primitive reptilian **brain** stem and working upward to the higher primate functions of the cortex. In addition, there are probably a number of evolutionary remnants present in the chemical pathways of the various neurotransmitters, peptides and other chemicals used in the **brain**" and while "such arguments contain more speculation than facts (they) suggest that the unconscious mind arises out from a more primitive **layer** of the **brain** which is not yet capable of secreting "higher" conscious thought" (1988, p.107).

It is anyhow undeniable that dogs engender dogs and cats, cats; and that such is the base-ment of identity and **organizational closure** in systems.

→ (see also: **Ideal-type**)

As explained by C. WADDINGTON, through his concept of **epigenetic landscape** (1977), evolutive **change** of an archetype does never occur freely in a vacuum.

As a result of its archetypical inheritance, any **organism** is endowed with *limited* (even if within a considerable potential for **adaptability**) possibilities of development from its **auto-genesis** on, and is thus able to construct itself only through a *pre-constrained morphogenesis*, in **interaction** with its **environment**.

0146

ARCHITECTURE (von Neumann's)

→ von Neumann's architecture

0147

ARGENTINE ASSOCIATION FOR GENERAL SYSTEMS THEORY AND CYBERNETICS ¹⁾

This Association was created in October 1976, originally under the name of Study Group of Integrated Systems. It was the first systems society in Latin America. Its main objective is the study and the diffusion of systemics and cybernetics through lectures, tutorials, seminars, and production of series of translations, and original papers and booklets ("Cuadernos", of about 100 pages each)

It organizes seminars and study groups on more specific subjects, or for disciplinary groups. Since 1992, an annual meeting gathers Argentine systemists and cybernetists, around some specific subjects. The Association also promotes visits of foreign systemists.

It published in 1992, in Spanish, the first Dictionary of Systems and Cybernetics, in collaboration with the **Instituto Andino de Sistemas** of Perú.

0148

ARGUMENT (Ad hoc) ³⁾

An hypothesis or conjecture introduced to solve an hitherto insoluble problem.

One wonders if some hypotheses very far away from **common sense** and not verifiable, introduced for example in some scientific **theories**, are not simply a way to "get out of the trouble". Changing the basic conditions of some **phenomena** and/or **theories** does not seem a very satisfactory option. (See John BARROW: "Is nothing sacred?", 1999).

These doubts were already aired by the French philosopher and epistemologist G. BACHELARD (1884-1962) ("La Philosophie du Non", 1949).

It is however doubtless that the very different **abduction** (PEIRCE) (1839-1914) is highly valuable in terms of **creativity**. Without the resulting "educated guesses", **knowledge** in general, and science in particular, would remain finally bogged down into static conservatism.

The difficulty is to differentiate **abduction** at its incipient state from useless imagination.

An example of genial **abduction** was WEGENER's (1880-1930) idea of continental **drift**, whose value was only recognized various decades later.

0149

ARGUMENTATION ANALYSIS ¹⁾²⁾

An ordered **presentation**, preferentially in graphical or matricial form, of the various significant opinions that can be identified on some **issue**.

This **method** can be very useful in order to avoid what J. WARFIELD calls "**underconceptualization**", "**clanthink**" or more generally muddled thinking.

It provides a sound foundation for **conflict** resolution, **conversation**, negotiation and **design**.

0150

AROGENESIS ¹⁾⁵⁾

An emerging jump in an **evolutive process** (W. SCHWEMMLER, 1991, p. 152)

0151

ARRAY (Activity) ²⁾

A **set of data** relative to a system's **behavior** organized in the form of a two- or three-dimensional **matrix**. (After G. KLIR, 1975, p.154)

G. KLIR uses such arrays – which can be processed – for experimental research.

0152

ARTICULAR RELATION ²⁾

Any **connection** device that provides a number of **degrees of freedom** in a **relation** between two **elements** or **structures**.

This notion was introduced by the French physiologist P. VENDRYES (1973, p.88) and is a generalization from the articulations between bones.

VENDRYES explains that no movement would be possible if bones were rigidly united. Freedom of movement depends on the possibility to adopt a number of different relative positions, as flexion, extension, rotation, etc... However movement could not be coordinated if the **relations** were totally undefined. The ligaments and their **connections** with the bones and muscles provide a more or less extensive **program** for mobility **relations**. This **program** is framed within defined **determinisms**, but, at the same time, within this **frame** it allows for a **variety of combinations**, and much more so when there is a **chain** of articular relations, as for example from the shoulder to the fingers. In VENDRYES terms: "Thanks to its elasticity, a muscle admits articular **indeterminism**; by its contractibility it imposes a **determinism**" (p.90) As a result, a number of more or less

random options do exist. But any defined movement selects only one and thus imposes at some moment, in some situation and for a limited **time**, a specific **determinism**.

According to VENDRYES the articular relation concept can be generalized to any relation wherein a number of undefined possibilities co-exist, but where only one can be selected (excluding all others) at any specific moment.

As an example, he gives the articular relation between words in a **language**.

The **analogy** with **decision** mechanisms in general is also striking.

0153

ARTIFACTS ¹⁾

"Things fashioned by rational beings with the help of some technique whether primitive or advanced" (M. BUNGE, 1979, p.209)

BUNGE comments: "An artifact is not just one more thing but a thing belonging to a kind that did not exist before the **emergence** of man or some other rational being. Artifacts may be regarded as constituting a whole new **level** of reality, namely the **artiphysis**... Artifacts are at the heart of human society and have properties absent from natural things" (Ibid).

It should however be remembered that the beginnings of rationality are ill-delimited: some apes make and use very simple artifacts, and also some Galapagos finches observed by DARWIN. Even spider's webs or beehives could be considered as artifacts constructed either by individuals or by collectivities, not obviously rational in the commonly accepted sense.

Construction of artifacts seem to be a **living systems'** capability still in full course of **evolutive development**.

The multiplication of artifacts deeply transforms the relation between man and the planetary **ecosphere** because it tends to create a global human **invironment** more and more distinct from the global **environment**.

The same **effect** is also present at more local **levels**: we are becoming "synthetic fishes in a plastic aquarium", with ever lessened contacts with our natural **environment**.

0154

ARTIFICIAL EVOLUTION

→ Evolution (artificial)

0155

ARTIFICIAL INTELLIGENCE ^{3) - 5)}

"The creation of **algorithms** and systems that exhibit intelligent **behavior**, including activities such as adaptive and **heuristic programming**, cognitive **process modelling**, **expert systems**, natural **language** processing, and **neural networks**" (G. FORGIONE, 1991, p.64)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This definition covers a wide area of quite different subjects. It is much more than, in K. KRIPPENDORFF's words: "A branch of computer science concerned with the **programming** of computers so that they exhibit apparently intelligent **behavior**, e.g. the **design** of **robots**, chess playing **automata** or theorem proving machines" (1986, p.4)

The "apparently intelligent **behavior**" conforms to the **TURING's criterion** according to which a "**machine**" should be considered intelligent if an **observer**, unknowing that she/he is dialoguing with a **machine**, cannot differentiate it from a human being.

According to M. MINSKY, an A.I. device must have an **understanding**, at least rudimentary, of its own **problem solving processes**. He believes that, if one endows it with a **model** of its own workings, it could finally improve itself.

This seems questionable, at least for two reasons:

- **GÖDEL's Incompleteness theorem** may not allow any system to contain a complete **model** of itself.
- If the **model** is introduced from outside, the predominance and necessity of natural intelligence is reestablished.

FORGIONE's definition reflects the evolution of the field, already observed in 1980 by M. BODEN who wrote that: "Artificial Intelligence cannot be expressed in the terminology of traditional **cybernetics**, which focusses on **feedback** and adaptive **networks** and which defines **information-processing** in quantitative rather than qualitative terms" (1990, p.30)

E. ANDREEWSKY states: "Two main axes which, to judge by current debates, appear to be **antagonistic**, characterize the **cognitive models** of Artificial Intelligence: the so-called '**classical**' Artificial Intelligence where **cognition** is considered from a "software" viewpoint (insofar as it concerns, as in computer **programs**, "computation" on **symbols**) and **Connectionism** where **cognition** is considered as if "emerging" from the **brain** and its neurons. These axes define different, but nevertheless very complementary, points of view on mind" (1993, p.189)

And "**Connectionism** is considered by the tenants of classical Artificial Intelligence as a resurgence of **Behaviorism**, with the negative connotations associated to this approach. For **connectionists**, classical Artificial Intelligence is merely a "Spanish inn", insofar as the **rules** (or the meta-rules) of reasoning are given to the system" (p.194) (Note: In Spanish inns of old you were supposed to find only what you brought in yourself)

In fact, the classical view on A.I. implies that no intelligent system can work without a **program** of **algorithms**, i.e. a software. This is probably true, but how are these very **algorithms** constructed?

The **connectionist** answer tries to explain this point through the concept of "spontaneous" upbuilding of **patterns** from unplanned **interconnections** in the **network**. Furthermore, the **representations** acquired by the **network** are seemingly spread out over the whole **network**, in a kind of **holographic** way. But how do these **patterns** become fixed and how are the **rules** to construct the **network** generated? The very general topic of **order** from **randomness** lurks behind these question marks.

The problem seems to be closely related to the **autogenesis** one and, as said by ANDREEWSKY, *both* viewpoints are probably needed. Remains to be seen how they can be interconnected and integrated.

→ "**Power laws in fractal structures**" and "**Autogenetic systems precursors**".

Still a different angle is generalization through **induction**, as for example in the famed BACON program which "rediscovered" several classic physical laws: KEPLER's law of planetary motion; NEWTON's law of gravitation and BOYLE's law of gases, among others.

Generally speaking, D. GREGORY describes as follows what he calls the basic "realist" axioms, **problems** and **goals** of A.I.

"Axioms:

- **Knowledge** is a commodity. We can trade it, teach it, learn it, forget it, remember it, represent it, discover it...
- **Knowledge** is distinct from its knower – just like **data** are distinct from computer disks
- **Knowledge** is **sets** of true **facts** together with **rules** for combining them
- **Knowledge** can be reduced to **sets** of primitives – just like **matter** is ultimately reducible to fundamental particles" (1993, p.67)

(All these views are controversial, some of them highly so: **Knowledge** should be only acceptably understood here in T. ÖREN sense (see "**Knowledge (Taxonomy of)**")

"Problems:

- To elicit **facts** that are free of the distortions produced by the way they are known or described
 - To represent **facts** and their inter-**relationships** so as to capture the way the world really is
 - To specify a utilization engine that arrives at conclusions that are true in the world" (Ibid)
- (The words "**facts**", "**really**" and "**true**" should be carefully pondered in order to cautiously relativize their use. See for example "**Club of Rome**" models and "**Systems dynamics**")

"Goal:

- To build an Artificial Intelligence: a disembodied, artificial subject matter expert with whom **conversations** are possible" (Ibid)

D. GREGORY's conclusion is that "A.I. research seeks to understand the principles by which pragmatically and **semantically** interesting **behaviour** can be produced with **syntactic** machinery" (p.63)

Such a **mechanistic** and more or less **reductionist** view is widely, but not universally accepted.

0156

ARTIFICIAL INTELLIGENCE: dogmas and metaphors³⁾

As stated by S. GOONATILAKE: "Broadly speaking, it could be said that there are two main aims of people engaged in AI research. The first is building 'smart' **machines** or what could be called 'technological AI'; the other aim of AI researchers is to build **models** of **cognitive processes**, thereby helping one to understand the mechanisms of the mind" (1991, p.108)

Both groups brought into the subject their specific preconceptions (or even prejudices)

P.R. MEDINA MARTINS and L. ROCHA consider that the following dogmas have, until quite recently, "framed not only the kingdom of artificial systems but also – more deeply – their designer's minds:

- the dogma of the logical mind
- the dogma of the disembodied mind
- the dogma of the timeless mind
- the dogma of the adult **observer**
- the dogma of **objectivity**
- the dogma of the "in" and the "out" (1992, p.683)

These dogma are rooted – according to the authors – into two main interrelated **metaphors**, i.e. "the **brain** as a *serial* computer" and "the mind like a computer"

The implicit use of this conceptual **frame** led to **reductionist** views on human **brain** and intelligence, which created a number of senseless problems in psychology and also brought artificial intelligence to a conceptual dead end (If and when one admits that A.I.'s only aim is or should be to mimic natural intelligence, which is not obvious). Gigantic, but rigid basically sequential **algorithms** can obviously not replace nor reproduce the simultaneous and parallel workings of **neural networks**, notwithstanding the fact that sequential computers and some **expert systems** obtain specific results which are out of reach of natural intelligence.

As noted by G.J. DALENOORT: "... artificial intelligence went on for some twenty years in constructing **programs** that could do something that on the outside was similar to what humans could do, without bothering at all how this capacity could have emerged in the human system" (1987, p.14)

As **meanings** are always "human" **meanings**, any **symbol** used in a classical A.I. **program** has necessarily been human constructed, and this also true for the **program** used, which is not endowed with anything more than rigid **binary logic**, sequently applied in a rigorously predefined way. **Binary** computers have thus no autonomous **learning** capacity and, consequently, are no satisfactory **metaphors** for natural intelligence.

0157

ARTIFICIAL LIFE⁵⁾

The creation of collective artificial units able to spontaneously construct complex **behavioral patterns** through **cooperation** and shared **information**.

Artificial life is, of course, not biological (Nothing to see with Dr. FRANKENSTEIN's creature). It is either computer modeled, or consists in devices assembled from mineral and electronic **elements**, which somehow mimic some **living systems behavior**.

The first A.L. device was Grey WALTER's **Machina speculatrix**, unfortunately merely considered at the time, as a kind of amusing **cybernetic** toy, after which it was forgotten for about 30 years (along with the French A. DUCROCQ's electronic foxes)

Artificial life is thus a quite new field of research. C. DELAYE et al in France, C. LANGTON's team in the U.S., L. STEELS in Belgium among others, are exploring "**cooperation** between distributed **agents** through **self-organization**" (STEELS, 1990).

Artificial life would be based, in terms of C. DELAYE and B. CORBARA on: "...reactive **agents** which would not possess any **representation** of themselves, nor of their **environment** and whose **behavior** is based on **stimulus/response mechanisms**" (1993, p.840)

This model is based on an **analogy** with some **colonial** animals, as for example **Dictyostelium discoideum**. However, until now no specific socialization factor, comparable to cyclical AMP, has been demonstrated to exist.

In any case, artificial life, just as the natural one, is basically a social **phenomenon**, with eventually (in the French researchers terminology) various **emergent levels** of **complexity**: collaborating **reactive agents** into super-agents, etc... (Ibid., p.841)

G. PASK has however argued that much of the qualities of **self-organizing systems** are determined by their fabric. As proteins are different from electronic chips, artificial life could be similar to natural one in the **self-organizing** aspects, but probably not much more than that.

→ **Automaton (Learning); Parallel Distributed Processing**

0158

ARTIFICIAL LIFE 2⁵⁾

The creation of new living **organisms** through the assembly in laboratory of new composite genomes.

This biological artificial life is widely different from either the creation of societies of cooperative **robots**, or **computer modelling** of possible artificial **organisms**.

Research in this field is just beginning at the Institute for Genomic Research of Doctors CRAIG VENTER and Claire FRASER in Maryland (The Economist, January 30th, 1999).

The possible development of this type of project should be closely monitored, in view of its considerable potential for revolutionary **transformations** in biology and **ecology**.

0159

ARTIFICIAL LIFE (The Seven Commandments of)¹⁾

The following is a shortened synthesis of the subject as presented by C. EMMECHE (1994, p.17-22)

"In its ambitious version, the **concept** of artificial life encompasses the following ideas.

"1. The biology of possible... artificial life deals with **life as it could be**... Biology today is only the biology of actual life. It must become a biology of any possible **life-forms**.

"2. **Synthetic method**. Where traditional biological research has placed emphasis on analyzing living beings and explaining them in terms of their smallest **parts**, the artificial-life perspective attempts to synthesize life-resembling **processes** or **behavior** in computers or other media.

"3. **Real (artificial) life**. Artificial life is the study of humanly created systems that exhibit **behavior** characteristic of natural **living systems**... They are designed by us. The **behavior** however is produced by the artificial life itself.

"4. All life is **form**. Neither actual or possible life is determined by the **matter** of which it is constructed. Life is a **process**, and it is the **form** of this **process**, not the **matter**, that is the essence of life.

"These four theses are related"

There are moreover "three additional commandments about the way in which artificial life must be constructed:

"5. **Bottom-up** construction. The **synthesis** of artificial life takes place best via a principle of computer-based **information processing** called "**bottom-up programming**": at the bottom many small units and a few **rules** for their internal purely local **interaction** are defined (This is the real **programming**). From this **interaction** arises the coherent "global" **behavior** at the general level: a **behavior** not previously programmed according to specific **rules**.

"6. **Parallel processing**. While **information processing** in a classical computer takes place sequentially ... the principle for **information processing** in artificial life is based on a massive **parallelism** that occurs in real life.

(Note: i.e., reflecting the **simultaneous activity** of many individual **elements**).

"7. Allowance for **emergence**. The essential feature of artificial life is that it is not pre-designed in the same **trivial** sense as one **designs** a car or a **robot**. The most interesting examples of artificial life exhibit "**emergent behavior**".

0160

ARTIFICIAL SELECTION

→ **Selection (Artificial)**

0161

ARTIPHYSIS¹⁾

The global **set** of **artifacts**

This neologism is used by M. BUNGE (1979, p.209)

The present research into "**artificial life**" gives a much wider dimension to BUNGE's assertion that artiphysis is a whole new level of reality. It could become a kind of globally organized artificial **ecosystem** whose future **relations** with the natural one opens a whole field of new questioning.

0162

ARTORG²⁾

Artificial organism.

This neologism has been sometimes used during the fifties and sixties. It was never widely accepted.

0163

ASCII Code⁵⁾

A basic **code** made of **bytes** that is used to represent a common **language** in a computer.

8 **bits**, each of it with the value 0 or 1 (or cells in a **TURING Machine**) make a **byte**. There are thus 2⁸, i.e. 256 possible distinct combinations, which is quite sufficient for example for common **alphabets**, with punctuation and special **signs**.

0164

ASILOMAR CONVERSATIONS¹⁾

The periodic meetings of a number of systemists in Asilomar, California.

The general goal of these meetings, originally inspired from the **Fuschl Group Conversations**, is to freely exchange views about specific human **issues** - as for ex. **education**, social **design**, social **organization**, social **awareness**, the future of societies, etc...

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

These conversations start with a general agenda, but develop in an open way through free debate in subgroups which define their specific agenda for the consideration of more precise aspects of the general agenda.

The conversations conclusions are not prescriptive, but could be called "inspirative".

0165

ASSESSMENT (Collective reciprocal)^{1) - 4)}

A process of reciprocal **perception** and/or **information** leading to a shifting collective **behavior**.

D.M. GORDON showed that work in the ant-hill is a collective **distributed process** based on an also collective **perception** of the global needs, arising out of shifting **tasks allocation**, which in turn arise out of numerous **interactions** between individuals. (1995, p.50-7)

This type of **processes** obviously would deserve a general systemic research, because it is probably present in all kinds of **social systems**, from cells to **human systems**.

0166

ASSESSMENT in systemic terms^{1) - 4)}

A. CASELLES proposes "a theoretical approach to all kinds of **forecasting** and **control problems**" considering "**General Systems Theory** ...specially adequate to the most difficult ones" (1993, p. 1285-89)

Applying his proposal to technology assessment, he suggests a **frame** "to begin the identification **process** of the **elements** and **connections** involved... in each technology assessment case", as well as a mathematical **model** taking in account the following factors:

- Required services depending on **population** implicated and on unitary demand respect to each service;
- **Population** implicated (based on a demographic **submodel**);
- Unitary demand (for example, all urban transport made by private cars makes the **unitary demand** of street surface higher than when public transport is used);
- Effective capacity to produce services;
- **Resources** to services; an **input variable** that enters the **resources** distribution among services, made by managers;
- **Resources** required by each technology;
- Offered services (producing an income);
- **Resources** consumption and **operation** (which produce a **cost**)"

R. PETRELLA (Director of the Program "Forecasting and Assessment in Science and Technology" of the European Union) writes: "... Technology Assessment is the **set** of procedures and **means** at the disposal of a society for the **understanding** of the nature and im-

pact of scientific mutations, development and uses of technologies and for research about their usefulness, their economical feasibility, their social relevance and value" (1993)

This confirms that assessment, specially in technological matters, is much more than a simple study of technical and economical adequacy of some innovation, confirming the usefulness of CASELLES' proposed systemic **methodology**.

However, his list of technical **criteria** should be expanded in order to take in account some other important aspects, as for instance: **Costs** of **resources** renewal, or impact of their exhaustion; impact on **ecosystems**; social benefits and **costs**; probable duration of usefulness, etc...

To make this clearer, CASELLES' **criteria**, if applied for example to the realization of the Kazakhstan irrigation scheme - which ruined the whole Aral Sea **ecosystem** and the human system depending on it - would have passed it with flying colors. The purely technical and economical **criteria** applied where wholly insufficient to predict possible **side-effects** of different types.

0167

ASSIMILATION¹⁾

Integration of external factors into a system's **structure**.

J.W. SUTHERLAND considers assimilation as the "complementary pole" of **accomodation**, which is merely a temporary or more or less lasting and reversible **adaptation** of the system to external variations.

The concept is somewhat difficult to conciliate with **autopoiesis** and **organizational closure**. Any system can assimilate only that which is compatible with its basic nature. Besides, assimilation seems possible only when the system still possess a high degree of **redundancy** (see **ageing**, **order from noise**).

Assimilation within the individual system, is *not* the mechanism, or at least the main mechanism, of **evolution**. This last comment commands however two caveats:

- The acquisition of new **habits** may well predispose in either a positive or negative way, the individuals of some species to the **transmission** of **dormant** or new traits.
- In the human species, mental assimilation of newly acquired **concepts**, **percepts** and symbolic associations seems to be directly transmissible through **communication**, something that KORZYBSKI called totalization through **time-binding** (1950b).

0168

ASSOCIATION²⁾

"The **relation** which is **commutative** and **connected**" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.33)

Grains of sand which accumulate in a dune are related in an associative way, since this way is **commutative** (The **order** in which they accumulate is irrelevant), and **connective** (since no **element** needs of any intermediary one to be in contact)

Association is thus a simple, non-**structural** and non- **functional relation**, at least in the **meaning** proposed by FEIBLEMAN and FRIEND. It is here the most primitive and rudimentary form of **coordination** among **elements**.

It reflects however a **trend**, generally induced by common conditions imposed to the **elements** by the **environment**, as for example dominant winds on sand dunes.

The generally accepted sense in social psychology and sociology goes quite farther than this and includes the **results** of closeness, i.e. defined **interactions** in **groups** and **social systems**.

0169

ASSOCIATION (Potential for functional)¹⁾²⁾

The existence of conditions in **elements** that could allow for the **emergence** of significant **relationships** among them.

Good examples are the combinatory potentials of chemical **elements** as a result of the different **states** of the electron shells of their atoms.

0170

ASSOCIATIVITY²⁾

The propensity of **elements** to form **links** and create **networks** or **structures**.

The most elemental forms of associativity are seen in **composite systems** and in **colonies**, where **subsystems** are not yet clearly differentiated. Such forms tend however in some cases to evolve toward much more strongly **integrative** types of **organization**. Any system is a more or less highly organized reunion of associated **elements**.

0171

ASSOCIATOR¹⁾

"The **subsystem** which carries out the first stage of the **learning process**, forming enduring **associations** among items of **information** in the system"

This one of J. MILLER's 20 critical **subsystems** (1978, p.3)

0172

→ Italian Association for Research on Systems

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

0173

ASSUMPTIONAL ANALYSIS ²⁾ - 4)

A **methodology** to reveal hidden assumptions of **stakeholders** in a **group** or **organization** confronted with some difficult **situation**.

This **methodology**, proposed by I.I. MITROFF and H.A. LINSTONE, is described by them in their 1993 book. Their general view is that it is "far better to debate a question without necessarily settling it than to settle a question without debating it" (p.146) Indeed, this last way is the best recipe to obtain an incomplete or false view of a **situation** or **problem**.

However, questions are settled without debate at least partly because their do not come out clearly and as a result, are easily ignored or jumbled. To make them appear clearly is specially important when they include conflicting views as held by the different **stakeholders**, because this is the only way to obtain a critical evaluation of the whole matter under consideration.

According to MITROFF and LINSTONE, the first step is to find out who are the **stakeholders**, that can affect or be affected by the **situation** as it is or as is could evolve. This they do by establishing a **graph** of all **stakeholders** (p.141). For example, in the case of a drug company, these are: the customers and patients; the physicians; the pharmacists; the suppliers; the salesmen; the competitors; government agencies; the holding company; the company management and the stockholders (not to be confused with the much more general **class** of the **stakeholders**!). In this way, it will become possible to obtain a most complete view of the **situation**.

The second step is to make the different **groups** of **stakeholders** expose their assumptions, which are mapped one by one into grids whose coordinates are "certainty-uncertainty" and "least to most important" (p.144)

In this way most hidden aspects can be brought to light and seriously debated. J. WARFIELD's **Generic Design** provides quite similar **methods** to avoid **underconceptualization** and incoherent debate (1994b).

Anyhow, assumptional analysis is by nature an open **process**. M. JACKSON considers that even after a synthetic list of assumptions has been established and a rating chart constructed (see hereafter), this is still a mere compromise among different- and possibly divergent- opinions. Thus "assumptions (should) continue to be negotiated and modified...for as long as progress is being made" (p. 228, 2000)

It is moreover obvious that the **issue** or **situation** may evolve. Accordingly assumptions may never be definitive, and corrective **iterations** of the analysis may be needed.

0174

ASSUMPTIONS RATING CHART ²⁾4)

After due and as complete as possible tracking of the respective assumptions of all **stakeholders** about some **issue** they should be evaluated, ordered, and rated according to their relative certainty and importance.

This is best done by constructing a chart with two perpendicular axes; the one from most to least certain, and the other from most to least important (M. JACKSON, p. 228, 2000)

The known Eisenhower graph on respective importance and urgency of issues- as well constructed along two axes- is also about assumptions ratings

0175

ASYMMETRICAL DEPENDENCE ²⁾

The dependence of systems on a lower **level** of **complexity** in relation to higher **level** ones in **organizations** or **ecosystems**.

This is a characteristic **relation** in **hierarchic systems**, where lower **levels** of **organization** depend on **regulations** and **controls** by higher **levels**.

More generally, any system or **subsystem** finds itself within a relation of asymmetrical dependence in relation to its **environment** or **suprasystem**. Even if and when it is able to modify its **environment** in a way more suitable to its necessities, such possibilities are limited by its **archetypical survival** needs.

It should be noted however that higher **levels** are also dependent of the lower ones, which provides them with the basic **inputs** they need in order to exert their **roles** as **regulators**, **controllers** and **deciders**.

0176

ASYMMETRY ¹⁾ - 2)

1) "The differentiation of one half from the other" (G. BATESON, 1973, p.353)

2) "A union of unequal opposites, the coexistence of two different, opposite poles in a unity" (H. SABELLI & L. CARLSON-SABELLI - 1992, p.660).

The SABELLI's view asymmetry, the general result of **symmetry-breaking**, as the fundamental cosmic order in relation to the temporal **flow** of **energy**, as "Whereas mechanics (classical, statistical, relativistic, or quantum) postulates stationary and **reversible processes**, **thermodynamics** and **dynamics** postulate that **processes** asymmetrically tend to **attractors**" (p.661). Thus asymmetry is "imprinted in the **form** of every **object**" (Ibid.).

H. SABELLI observes that "this concept of cosmic asymmetry has been validated in our century, beginning with the discovery of the non-conservation of parity in beta decay, the optical rotation of atoms, the string theory of **matter**, the importance of highly asymmetric, **nonequilibrium states** in the **thermodynam-**

ics of **open processes**, the asymmetric preponderance of **matter** over anti-matter, the **time** asymmetric **collapse** of the wave function in quantum mechanics, the asymmetry of crystals of which rocks are made, the violation of gauge symmetry by superfluids, the lack of symmetry in magnets and fundamental biological asymmetries... Asymmetric **structures** lead to asymmetric **processes**, and in turn the asymmetry of **processes** becomes imprinted as **structural** asymmetry" (1991, 219-20)

G. BATESON writes about the step from bilateral **symmetry** to asymmetry (in living beings): "... either the asymmetry must be achieved by a **random process** or it must be achieved by **information** received from the outside" (p.373).

In both cases, **positional value** of the receiving **element** becomes very significant.

Asymmetry acts as a factor of **organization** and **complexification** because it corresponds to **distinctions**, leads to **complementarities** and opens more possibilities for **differentiation**.

This had already been recognized in the 19th. century by L. PASTEUR and well explained in 1942 by Ch. LAVILLE, who constructed a theory of **fields** asymmetry.

Contemporary ecologists, as R. MARGALEF for instance (1982), also admit that asymmetric exchange between **living systems** (as in **commensalism** and **symbiosis**) leads to an increase of their global **complexity**.

M. HAAS established a typology of asymmetries. (1967). He distinguished:

temporal - spatial - kinetic - entropic and allocational asymmetries.

Within the temporal asymmetries he signaled (among others, which seem less significant): - **fluctuations** - **tides** - **discontinuities**

Within spatial asymmetries he mentions (also among others, more specific of social and political situations): - **segregation** - **centralization**

His description of kinetic asymmetries seems too restricted to these same social and political situations. It makes sense however to distinguish, for instance: - mobility at different **rates** - immobility

As to kinetic asymmetries, they seem quite basically related to different **levels** of **entropy** production in different **parts** of a system.

As to allocational asymmetries, HAAS' **classification**, as related to socio-political systems is difficult to transfer to other types of systems because it implies **values** of different kinds.

→ **Trend (Asymptotic)**

0177

ASYNCHRONISM ²⁾

The existence of different **rates** of **propagation** of some **change**, or its **effects**, in **space-time**.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

Asynchronism is closely related to **anisotropy**.

It can be observed within a system, or in the **environment** at large. It seems to be closely related to **chaotic behavior**, because of the growing interferences in **time** between the different sequences of **propagation**.

0178

ATTENUATION ²⁾

The decrease in a **feedback cycle** resulting of a negative **amplification cycle**.

Attenuation corresponds to the progressive **damping** of the concerned **process** or **function**. When persisting, it may lead to their disappearance, by total loss of any capacity for regulating **fluctuations**.

(For the opposite, see "gain")

0179

ATTRACTOR ^{1) - 2)}

A limited **region** of the **phase space** (i.e. a point, or a **set** of points) towards which the **trajectory** of the system converges, tending to a **steady state** or **periodic motion**.

This is the concept of attractor according to classical **dynamics**.

There are two basic types of classical attractors (as opposed to strange, or **chaotic**, ones):

1.-The attractor may be a single point (or **state**) towards which the system's **trajectory** converges in a monotonic way. This implies, for example, a tendency to **asymptotic stability**. This was the original mathematical **meaning** of the term.

2.- The attractor may be "a closed **loop**, corresponding to **periodic motion**" (I. STEWART - 1989, p.45)

This is a characteristic of systems which undergo a **cyclical** or **cyclomorphical activity**.

The first case corresponds to any system strictly submitted to the **2nd. principle of thermodynamics**, i.e. whose **entropy** grows steadily or, more precisely, to which a **trajectory** and the corresponding **energy function** is associated, such as its **value** constantly decreases with **time**.

The second case corresponds to systems which retain **dynamic stability** by maintaining their internal **structures** and **functions** within closely defined **limits**. Such systems tend to produce the minimum **flow of entropy** compatible with their absorption of **energy** obtained from the **environment** (cfr. PRIGOGINE's **irreversible systems** with small **fluctuations** as opposed to other **irreversible systems**, which undergo giant **fluctuations** throwing them out of their **stability limits**; and also his principle of **minimum entropy production**).

Attractors are **sinks**, which means that the attracted system is submitted to characteristic **constraints**, from which, in principle, it cannot escape using its own means.

In **chaotic dynamics** the motion becomes **quasi periodic** ("The geometrical picture for quasi **periodic motion** in quasi **space** is a curve that combines two or more different "circular" motions") (L. STEELS, 1990, p.45)

Hence, a **variety** of more and more complex attractors, which correspond to "the qualitative **diversity of dissipative systems**" (I. PRIGOGINE and I. STENGERS, 1992, p.69)

R. SWENSON characterizes the attractor as "The **time-independent (time-asymptotic) state**, or **limit set**, that attract **initial conditions** from some **region** around its "**basin of attraction**", during a **set of time-dependent processes (evolutionary behavior)** as t_y , "(after D. RUELLE, 1981) (SWENSON, 1989, p.189)

The **concept** of attractor is thus connected with the idea of dynamic **irreversible change**.

However, there seems to be two different kinds of these:

- **Adaptive change** in systems endowed with **organizational closure**, which cannot escape the necessity to reach a final destructive stable **state** ("Death is equifinal" says Stafford BEER)

- **Innovative change by emergence**. "Evolutionary **behavior**" corresponds to this kind of **transformations** (see "**attractor (emergent)**").

Francis HEYLIGHEN defines the attractor as "a region of **state space** invariant under the **dynamics** (each **state** in the attractor is sent upon a **state** of the same attractor) (1990, p.496), such that it does not contain subattractors. This means that there are no **fixed points** inside the attractor. Each point in the attractor is sent on another point of the attractor. This accounts for a **model** in which there is both conservation of the **distinctions** between different attractors and variation within each attractor". (Ibid).

Attractors may become multidimensional. M. FARGE defines the attractor's dimension as: "the **set** of the points of the **phases space**, i.e. of all possible positions and velocities that can be visited by the system, containing the set of all solutions within the **limits** of a very long **evolution in time**" (1992, p.214)

While any attractor controls a **basin** or area that converges to it, this area can be very narrow. In such a case quite small **disturbances** may push the system out of the **basin** and force it to **convergence** toward another attractor. These jumps from one attractor to another, very far to be a purely abstract **model**, are the gist of many **collapses** affecting real **structures**.

0180

ATTRACTOR (Chaotic) ^{1) - 2)}

Also called "strange attractors"

D. BROOMHEAD describes the chaotic attractor in these terms: "(It)... can be thought of as a bag in the abstract **phase space** defined by the **variables** of position and momentum; the bag contains an infinite number of **periodic states**, all of which are unstable. 'Unstable' in this sense means that if, at some **time**, the **behavior** of the system can be approximated by one of the **periodic states**, the approximation error grows exponentially with **time**. The interesting thing - and the resolution of the chaotic paradox - is that the bag, *as a whole*, is stable. Once the system is in the 'bag', it cannot leave; rather it wanders, moving close to one **periodic state** as it diverges from another" (1990, p.23)

It is thus quite clear that **randomness** in **chaotic systems** is *confined* within a global **determinism**.

I. PRIGOGINE and I. STENGERS observe: "Chaotic attractors are not characterized by whole **dimensions**, as a line or a surface, but by **fractionary dimensions**. They are what is called, since MANDELBROT, **fractal varieties**" (1992, p.73) (see: "**Fractal dimensions**")

J. CASTI makes this clearer as follows: "(in classical attractors) regardless of the **dimension** of the overall **state space**, the **fixed point** has **dimension 0**, while the **limit cycle**, being a simple closed curve, has **dimension 1** These numbers are the *geometric dimension* of the attractor. At the other end of the scale is the situation in which the system is truly **random**. In this case, every point of the **state space** is eventually visited, leading to the attractor's having the same **dimension** as the **state space** itself. **Chaotic systems** with their strange attractors lie somewhere in between. For such systems, the attractor is clearly not such a primitive geometrical object as a point or a simple curve. Yet it is still a proper **subset** of the overall **set of states**" (1994, p.101) (and, consequently has a fractionary, or **fractal dimension**)

0181

ATTRACTOR (Dynamic) ^{1) - 2)}

A stable **states cycle** in a **network**.

ST. KAUFFMAN, who applies this **model** to biological systems, states: "... once a **network's trajectory** carries it onto a **state cycle**, it stays there. The **set of states** that flow into a **cycle** or that lie on it constitutes the **basin of attraction** of the **state cycle**. Every **network** must have at least one **state cycle**; it may have more" (1991, p.66)

0182

ATTRACTOR (Emergent) ^{1) - 2)}

An **attractor** characterized by a progressive drive away from **equilibrium** (1989, p.189).

R. SWENSON states that emergent attractors result from interacting **processes** – that eventually **bifurcate** – and are more complex than the **processes** that formed them (Ibid)

S.J. GAO and F.J. CHARLWOOD distinguish four fundamental types of emergent attractors: **Fixed point** attractor, **periodic** attractor, **quasi-periodic** attractor and **chaotic** attractor. They state: "... they represent qualitatively different **states** of the system in different **environments**. The adapting and evolving **behavior** of the system can be defined as the quantitative **change** (changes of position in the **state space**) and qualitative **change** (changes of type) of these emergent attractors" (1993, p.62)

As examples of emergent attractors R. SWENSON cites: non **equilibrium** points, **limit cycles** and **chaotic attractors**.

He opposes the emergent attractors to **equilibrium attractors** or points, "by definition characterized by a drive towards it".

The emergent attractor is thus equivalent to a **dispersion** or radiating center, i.e. a **negative** attractor that we could call a "repulsor".

According to SWENSON: "Emergent attractors are **non-linearities**, and **nonlinearities** are emergent attractors. The spontaneous **transformation** of a **set** of atomisms (i.e. **elements** or **components**) from an infinitesimal **fluctuation** to a globally coherent dynamical **limit set** of **macroscopic scale** is, by definition, a **nonlinear**, viz **self-amplifying process**; the effects of the **attractor** (drive away from **equilibrium**) become its causes (the further away it goes, the faster it drives) until some **limit** is reached.

"When the **nonlinear relation** ceases to exist, so too does the "object" (**flow structure**), and its global **space-time correlation** vanishes into incoherence". (1989, p.189)

0183

ATTRACTOR (Fractal) ²⁾

A discontinuous attractor which governs the **behavior** of a **complex system**

An attractor is said to be fractal if the **fractal dimension** is not an integer.

This subject is discussed under the headings: "**Basin of attraction**" and "**Fractal basin boundaries**"

0184

ATTRACTOR (Quasi periodic)

→ **Attractor (Toric)**

0185

ATTRACTOR (Stability of an) ²⁾

Capacity of an attractor to resist **perturbations**.

As stated By St. KAUFFMAN: "Attractors tend strongly to exhibit **homeostatic** return after **perturbation**" (1993, p.209). However "The **stability** of an attractor is proportional to its **basin size**, which is the number of **states** on **trajectories** that drain into the attractor. Big attractors are stable to many **perturbations**, and small ones are generally unstable" (1991, p.67)

This explains the **instability** in **chaotic systems**, where frequent jumps occur between smaller and smaller attractors that appear through **fractalizing bifurcations**.

For the concept of "basin size" see "**Basin of attraction**"

0186

ATTRACTOR (Thematic)

→ **Thematic attractor**

0187

ATTRACTOR (Toric) ²⁾

An attractor which "... describes motion made up of two independent **oscillations**" (J. CRUTCHFIELD et al., 1989, p.42)

Such a motion is "sometimes called **quasi-periodic**" (Ibid)

J. CRUTCHFIELD et al. point out that : " The important feature of **quasi-periodic motion** is that in spite of its **complexity** it is predictable. Even though the orbit may never exactly repeat, *if the frequencies that make up the motion have no common divisor*, the motion remains regular. Orbits that start on the **torus** near one another remain near one another, and long term **predictability** is guaranteed." (Ibid).

→ **Numbers (Prime)**

0188

ATTRACTORS and BEHAVIOR MODES MODELING ²⁾

J. Aracil proposes an association of **attractors**, as **models** and **behavior modes**.

"It is well known that a **dynamical system** can show many **attractors**. With each **attractor** we associate a **behavior mode**. The attractors represent the **states** where the system is normally observed. The qualitative study of **dynamical systems** is concerned with the study of **attractors**. A very important question, that literature has not dealt with however, is to study how the variation of the theoretical framework along the **modeling process** can determine the possibility of **emergence** of new **behavior modes** (new attractors). This problem is linked to the **emergence** of **bifurcations** in the modeling **process** in the precise sense to be stated below. In this way the **modeling process** can be related to the concept of **structural stability** and with THOM's **catas-**

trophe theory paradigm considered in its widest sense, as a theory of **morphogenesis**: the **morphogenesis** of new **behavior modes** through the **modeling process**". (1986, p.244)

The lack of such a qualitative enquiry was one of the main shortcomings of FORRESTER's **Systems dynamics**

0189

ATTRACTORS; A classification ^{1) - 2)}

K.De GREENE proposes the following classification of attractors:

"1. Points, like the static **equilibrium** points of **catastrophe theory**. Points can apply to both **linear** and non-**linear** systems.

"2. Periodic attractors, like **limit cycles** that apply, say, to interacting **populations**

"3. **Strange**, **Lorenz** or **chaotic attractors**: A system **state** can be related to a **basin of attraction**, but how stable the system is and where the system resides relative to the **boundary** of the **basin** may be unknown and unknowable. Indeed, the very existence of an alternative **basin(s) of attraction** may be unknown". (1990, p.161)

Furthermore "...minuscule differences in **initial conditions** may lead to the exponential expansion of these differences" (Ibid.)

A slightly different classification is possible: **Fixed point**: The simplest attractor. It corresponds to a generally monotonous **trajectory** of a non disturbed system toward a final **state**, for example: a real pendulum, submitted to frictions.

→ ("**Fixed point**")

Limit cycle: Corresponds to a closed **loop** within the **phases space**. This implies that the system's **trajectory** involves a series of non-disturbed **periodic oscillations**.

Toric attractor: Characterizes the **behavior** of a system simultaneously submitted to two periodic **oscillations**, independent from each other. The **structure** of these **oscillations** remains always predictable and possible to carry out, even when the **periods** are incommensurable.

→ "**Numbers (Prime)**"

Chaotic attractor: Corresponds to the **behavior** of a system simultaneously submitted to, at least, three **periodic oscillations** independent from each others. The simplest corresponds to systems of simple differential equations where the **phases space** is three-dimensional.

Even in these cases the **transformations** of the system are generally not predictable. An early example was the famous astronomical **three bodies problem** studied by POINCARÉ.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0190

ATTRIBUTE¹⁾

Any quantitative or qualitative property of a system, **subsystem** or any of their **elements** (Adapted from J. van GIGCH, 1978, p. 14)

This author adds: "Qualitylike" attributes of greater difficulties of definition and of measuring than their counterpart – the "quantitylike" attributes" (Ibid)

0191

AURA¹⁾

The **set** of the traces or **constraints** left over by a system after the end of its functional existence.

This stimulating systemic concept has been introduced by the French biologist H. PRAT. It can be applied to a fossil, or petrified wood, as well as to a sunken ship, or a destroyed empire, or the teachings of a great disappeared mystic or philosopher. (1971, p. 92-5)

At any moment the system contains its history and, when it functionally ceases to exist, something may remain of it. In J. BRIGGS and F.D. PEAT's words "Time is inflexible, and however, the past is continuously recycled, somehow maintained eternally" (1991, p. 145).

The aura corresponds to a kind of fossil **field**, i.e. a certain degree of **survival** of material and/or abstract **structures**, given the condition that there be no excessive disruptive **environmental activity** and that important **interconnections** between **elements** remain more or less intact, or correlatively transformed.

In some cases, the aura may even give birth to a new system. A curious example is the "Gustav Vasa", flagship of the Swedish navy, sunk in the 16th Century, forgotten for 300 years, then refloated in the 20th Century, and now a naval museum in Stockholm's harbor.

G. CHROUST gives a complementary **meaning** to the concept, asking how far the **effects** of teaching do extend in **space** and **time** and also, "what **size** can a **group** have such that one can still communicate effectively" (1999, p. 419).

These aspects can be mapped by using **graphs** and are also related to the **small world model**.

0192

AUSTRIAN SOCIETY FOR CYBERNETIC STUDIES¹⁾

This Society is one of the oldest in Europe. Its original name in German is "Österreichische Studiengesellschaft für Kybernetik". It was created in Vienna by a group of Austrian cybernetists under the leadership of F. de PAUL HANIKA and Dr. R. TRAPPL, who is still its President.

It publishes technical reports, principally on A.I. and hosts the editorial office of the "Cybernetics and Systems" Journal, whose Editor-in-Chief is R. TRAPPL.

It organizes in Vienna every other year since 1972 a "European Meeting on Cybernetics and Systems", whose proceedings are published.

It has been one of the co-founders, with the **ISSS** and the **Systeem Groep Nederland** of the **International Federation for Systems Research**.

0193

AUTOCANALIZATION²⁾⁵⁾

A **process** of self regulated **evolution** in the **biosphere** as a **whole**.

This concept has been introduced by V.F. Levchenko and Ya.I. Starobogatov.

In a more recent paper, Levchenko writes: "...canalizing factors include the **environment** which is not invariable with **time** but depends just on the **evolution** of both the **biosphere** itself and the **organisms** it is composed of" (1998, p. 106)

Self-regulation in natural systems was also suggested by François (1983), himself inspired by Ashby's "Principles of the **self-organizing system**" (1968)

Autocanalization is certainly significant for the understanding of Lovelock's GAIA (1979)

0194

AUTOCATALYSIS²⁾

A **process** in which the increase of an **element** in a system is enhanced by the concentration of the **element** itself.

The reaction's product is itself the **catalyzer**.

Figure: see entry **AUTOCATALYSIS**

**Autocatalysis**

From M. EIGEN and P. SCHUSTER: "The hypercycle" 1979 - p. 90

Autocatalysis is basically a **self-amplifying process**, but moved by a **cyclical positive feedback with relaxation phases**. It may however lead, in a limited **space**, either to a destructive supersaturation or, exceptionally to the **emergence** of a new **level of organization** of the **elements** reaching a **critical density**. K. KRIPPENDORFF observes that: "Autocatalysis is not to be confused with multiplication through **production**, including **self-reproduction** in which the **growth** of the **population** is an aggregate property of the productive capability of its individual members" (1986, p.5)

see figure left

0195

AUTOCORRELATION²⁾

"A statistical measure of the strength of association which exists between pairs of values of a **time series** as a **function** of the **time interval** which separates them". (T.F.H. ALLEN & T.B. STARR 1982, p. 262)

0196

AUTOGENESIS¹⁾

The appearance of a new system by association of formerly unconnected **elements**. (C. FRANÇOIS, 1989, p.72)

"In some sense, autogenesis appears as a absolute beginning. "Before" there was "nothing" (i.e. only scattered, unconnected **elements**); "after", we suddenly have a new system, immediately **morphogenetic** and **autopoietic**. The **event** is, partly, a **random** one. This is interestingly paralleled in John H. CONWAY's **game of life**, where it is the player who defines an **algorithm** for general genesis conditions whose potential content he ignores. He does not know in which way the system will develop, or if and when it could become blocked or destroyed. However, the original **random decision** remains inserted within the most general conditions of the game: **elements, rules, a field, limited or unlimited**".

"In this sense, however, autogenesis appears as a relative beginning" (Ibid).

"Before", there were significant antecedents: **elements** and an **environmental situation**. "After", we have some new entity born with and within these antecedents. What is new is the combination. However, it takes place within an **archetypal algorithm**, which represents a kind of **autopoiesis** at a higher **level** in **space-time**.

Some examples will make this clearer:

- The autogenesis of a complex and original living being⁵⁾.

Can result only from the sexual pairing of two previous systems of the same kind. What is autogenetic is the fusion of two half genomes, and more precisely of *these* two half

genomes, while trillions of other combinations were possible. This is quite akin to an irreversible **decision**, but in this case its significance, if any, remains undecipherable for us.

The **autopoietic** aspect is that each of these half genomes must be of the same species, in order to be able to construct a new viable **autopoietic system**. This means that, even considering that the new system is an original and unique creation, it remains within the **limits** of a more general **algorithmic** and combinatory **model**: in this case, the species. Future genetic manipulations could possibly modify this general frame.

- Neural autogenesis ⁵

According to V. CSANYI: "... in the course of **ontogenesis**, the human **brain** goes through phases of neural autogenesis, the phases of non-identical replication and identical **replication** and the **phenomena** of each phase (functional **differentiation**, rise of **hypercycles**, compartmentalization, **convergence**) can also be observed. The human **brain**, which consequently represents a **zero-system** capable of neural **evolution**, develops in the course of **embryogenesis**" (CSANYI, 1989, p.80)

- The autogenesis of a society ⁴:

The autogenesis of a society, as an **emergence** into a higher **level of complexity**, offers the same characteristics, but more general. A cultural example will be used, but others, biological, political or economical could be given.

A human society in its phase of autogenesis entails the progressive co-**assimilation** of various **heterogeneous** groups, bearing different cultural inheritances and coming for the first time in contact in some defined area (by invasion, immigration, colonization, etc.). In this case, the fusion **event** seems, at our **time-scale**, a slow and hazardous **process**. However, at the historic **time-scale**, it is really be a very short one.

What is leading to **autopoiesis** here is the common pre-existence of a **variety** of cultural traits. While different, they are all somehow related to the unavoidable **constraints** of societal **organization** in general, as any society needs in order to survive some specific **environmental** conditions, as well as basic **values** and **norms**, transmittable from one generation to the next. (FRANÇOIS, 1989, p.72-73)

→ **Autopoiesis; Epigenesis; Equipotentiality**

0197

AUTOGENESIS (From) to AUTOPOIESIS ²⁾

This transition results of the appearance of **replication** within hitherto not functionally interconnected **sets** of compatible **components** (CSANYI's "**zero-system**")

This author writes: "A system may contain several different kinds of **components**, which are all **replicative** units with diverse fidelity. Among these, **interrelationships** develop and, as a result, their **replication** becomes coordi-

nated. Gradually the **whole** system will start **replicating** as a final **replicative** unity. In the autogenetic **process**, the **organization** of the system and of its **parts** changes due to the **functions** of the emerging new **components**. Thus autogenesis is possible only while the **state** of identical **replication** has not yet been achieved. In that **state**, the system becomes functionally **closed** and its **replication** in **time** continues as long as the **environment** does not change. There are no further organizational **changes** initiated by organizational causes because new **functions** cannot originate... This end **state** of an autogenetic system is equivalent to what VARELA calls **autopoiesis**" (CSANYI, 1993, p.264)"

There are **time limits** to **autopoiesis**, because the capacity of any system to generate **accommodating** or **adaptive** responses to **environmental stimuli**, while considerable, is however limited: systems are maturing and finally **ageing**.

0198

AUTOGENETIC SYSTEM PRECURSOR (AGSP) ²⁾

A minimal **set** of **components** in a system in its initial **phase of autogenesis (zero-system)**, which has the potential to start producing **processes**. (After V CSANYI, 1993, p.263)

CSANYI explains: "A precondition for starting a **self-organizing process** in a **zero-system** is the presence of a minimal **set** of **components** which is able to replicate and which fulfills the following criteria:

"1. It contains at least one **cycle of component-producing processes**;

"2. At least one of the **components** participating in this **cycle** can be excited by the **energy flux** flowing through the system" (Ibid)

This **model** seems apt to cover autogenesis in future artificial systems as well as in actual **living systems**

It also explains the "jump" from autogenesis to **autopoiesis**, as Csanyi describes it: "During autogenesis, as **time** advances, an increasing part of functional **information** becomes **replicative information**. This can appear only as an extension of AGSP, that is, additional **replicative cycles** appear which are interconnected with the AGSP" (Ibid)

0199

AUTOGNOSIS ³⁾

The study of the conditions of conscious **knowledge** (Adapted from W. DILTHEY: Gesamtelte Schriften, 1922-1935)

This is a step forward from SOCRATES "Gnoti seauton". His membership of the Athenian **culture** of his time was implicit for him and at the same time subtly preforming his way of being and thinking.

Such cultural and historical conditions are proper to any individual **observer**.

Being this observer inserted in his specific culture at a precise historical moment, he thus acquires peculiar **reference frames** in some well defined psychical and mental **environment**.

This setting has been considered by Dilthey in his "Critique of speculative systems and nature explanation starting from **consciousness** facts and the historical march of world thinking" (Note: spanish translation used: the german original could not be located). Dilthey describes the result as "reality for myself".

Accordingly, autognosis is (or should be!) a permanent **process**, but at the same time subordinated to what has already been acquired by **learning** and training through former **experience**. It is a sort of sedimentation in an **autopoietic** way. Dilthey uses Goethe's term "Protophenomena". He also quotes BENCKE and says: "thought as such...analyses experience"...of course within the already acquired mental and conceptual frame.

Autognosis is closely related to modern hermeneutics, as proposed by Dilthey in his 1900 book on the "Origins of Hermeneutics"

0200

AUTOKINESIS ¹⁾

Capability for self-controlled (**autonomous**) movement.

This concept has been extensively elaborated by the French physiologist P. VENDRYES (1942)

It is exclusively proper to animals and up to a point to **artificial organisms** endowed with perceptive capabilities and **regulation** devices.

Throughout the scale of the animal reign, autokinesis grows with **complexity**. It will possibly be the same with intelligent **artificial organisms**.

Autokinesis would be impossible without **correlation** devices (senses, nervous system), empowering the system with possibilities to evaluate the **dynamics** of its displacement within its **environment**.

0201

AUTOMATA: A Classification ²⁾

According to M. BUNGE: "An automaton is a discrete and sequential system"

BUNGE distinguishes deterministic automata from probabilistic ones: "If lacking in spontaneity, i.e. acting only under external compulsion, the automaton is called **deterministic**. If **inputs** and internal **states** determine only **output** probabilities, the automaton is called **probabilistic**."

Deterministic automata are of interest mainly in technology, where highly reliable systems are desirable. Probabilistic automata are of greater scientific and philosophical interest, for

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

natural systems, such as **brains** and **communities**, are endowed with some spontaneity and seem to have strong stochastic **components**" (1979, p.263)

Some years after BUNGE wrote these lines, the development of the theory of **deterministic chaos** blurs somewhat the above **distinction**. But it also explains how an automaton, or system may function, being partly deterministic and partly stochastic.

G. KLIR proposed a different classification of automata, in accordance to their possible uses:

"1. Decoder-combinatorial automata which have the same **input** and **output variety** and in which the **mapping** between **stimuli** and **responses** is mutually unique.

"2. Prospective automata – combinatorial automata Prospective whose **output variety** is smaller than the **variety** at the **input**, and in which a single **response** is uniquely assigned to each **stimulus**, whereas the converse assignment is not unique.

"3. Retrospective automata – sequential or complex **random** automata, the **output variety** of which is larger than their **input variety** and where a single **stimulus** is assigned to each **response**.

"4. **Function** generators – sequential or complex automata which, as a result of at least one **stimulus**, produce in their **output** a **response** that is either a **determinate** or a **random function of time**.

"5. **Self-organizing** automata – sequential or complex automata, in which the **variety** of the **responses** produced by a given **stimulus** can change (as a **rule**, diminish) under certain circumstances." (1965, p.37)

This last class is very important as it corresponds to all natural and artificial **autopoietic** systems.

0202

AUTOMATA (Initial Configuration in cellular)^{2) - 5)}

A **set** of cells or **elements** arranged in some specific order which constitutes the initial **state** of the cellular automata.

Curiously, some initial **configurations** cannot be produced starting from any previous **configurations** (see **Garden of Eden**).

While some **configurations** can lead to **self-reproduction**, most cannot.

In some cases the **rules of transformation** of the cellular automata are embedded within its initial **configuration**.

0203

AUTOMATA NET²⁾

A finite **net** of interconnected **elements** which operate on basis of an on-off logic.

This is a very general **model** that has been used in genetics (St. KAUFFMAN, 1969), in **models** of the cerebral cortex (D. DUBOIS, 1991), in **connexion machines** (T. TOFFOLI & N. MARGULIS, 1987) and quite recently in distributed **artificial intelligence** (R. BROOKS (1989); C. LANGTON; L. STEELS, 1990)

Automata nets present characteristic **emergent** properties and **behaviors**, which depend on the nature of their **interconnections** or "wiring".

The **net** must have **constraints**, i.e. some **connections** being permitted and other ones suppressed. **Flows** through the **connections** can be permanent or more or less **intermittent**. Furthermore, such **nets** tend to subdivide into local and specialized **subnets** and, as a result, simultaneous **events** in different **parts** of the **net** do not propagate their **effects** instantaneously and generate very complex **nonlinear** (and sometimes **chaotic**) **behavior**.

Automata nets present very numerous alternative possible **steady states** and in some cases, undergo giant **fluctuations** that may lead to **bifurcations** and **dissipative structuration**.

Once the **set** of internal **states** can be specified through a finite **state transition matrix**, the automata net becomes a **finite automaton** or, if it produces **outputs**, can be assimilated to a **sequential machine**. This does not however make it wholly predictable.

0204

AUTOMATA (Reliability of)^{3) - 5)}

H. ATLAN states as follows the problem of comparative reliability of natural and artificial **machines**:

"A reliability like the one of the **brain**, able to function continuously, while **cells** die every day without replacement, with unforeseen **changes** in the blood's **flow**, volume and pressure **fluctuations**, not to mention amputation of important **parts**, which perturbs only in a very limited fashion the whole **set's performance**, is not matched in any artificial automata. This fact had already struck J.von NEUMANN (1966), who was seeking to better the computer's reliability and could not imagine such a reactive difference to **random environmental** factors of aggression (**noise**), if not related to a basic difference in the organizational logic of the system. "**Organisms**, with their faculty to "swallow" **noise**, could not be understood as just only somewhat more reliable than the known artificial **machines**, but as systems whose reliability could be explained only by qualitatively different principles of **organization**" (1972, p.23)

"VON NEUMANN, WINOGRAD and COWAN's (COWAN, 1965) investigations aiming at the discovery of construction principles for automata whose reliability would be greater than their **components**'...led to the definition of nec-

essary (and sufficient) conditions of feasibility of such automata). Most of these conditions, (**redundancy** of **components**, **redundancy** of **functions**, **complexity** of **components**, delocalization of **functions**) lead to a kind of compromise between **determinism** and **indeterminism** in the build up of the automata, as if some measure of **indeterminacy** should be necessary, from a certain **level** of **complexity** on, to allow the system to adapt itself to a certain **level** of **noise**" (ATLAN, 1972, p.23).

0205

AUTOMATA (Rules of transformation in cellular)^{2) - 5)}

Those **rules** which prescribe the ways in which the **elements** of the automata will be created, maintained or destroyed at each **transition** from one to another **state**.

Different rules are possible, leading to:

- a seemingly **random transformation**
- **self-reproduction**
- blocage in some definitive **state**
- some **cyclical transformation** of the automata

→ **Game of Life**

0206

AUTOMATA (Self-reproducing)^{3) - 5)}

In L. LÖFGREN words: "... an automaton where the **behavior function** *F* is considered self-reproducing if, from some **stimulus**, it produces another automaton with the same **function** *F*. This leads to the question whether a **function** can contain itself in its **range**" (1978, p.247)

In view of **GÖDEL'S incompleteness theorem**, this does not seem to be a very promising proposition.

However ATLAN states: "...up to now the only self-reproducing automata known are the natural **machines**, i.e. the living **organisms**" (1972, p.22). But even this view should be qualified: reproduction by division is not the same **process** as sexual reproduction. Besides, self-reproduction has now a specific **autopoietic** meaning.

ATLAN also writes:

"a) Living **organisms**' specificity is related to (cybernetic) principles of **organization**, and not anymore to irreducible vital principles

"b) Once these principles are outlined, nothing should impede their application to artificial automata, whose performance could equalize those of living **organisms**" (p.22-23)

0207

AUTOMATA (Self-reproductive cellular)^{2) - 5)}

An automata able to reproduce itself, i.e. to produce a copy of itself after a number of **transformations**.

The project of a self-reproducing cellular automata was initially formed by J.von NEUMANN.

Self-reproduction in a cellular automata is clearly different from **self-reproduction** in the **autopoietic** sense, whose **models** were established later. However, both are obviously related

It is debatable if the appearance of a "copy" of the initial automata in some other **region** of the **substrate** is equivalent to the **endogenous self-reproduction** of a system endowed with **organizational closure**.

H. Maturana states: "Cells do not construct other cells, they just divide into two of the same kind, like in the fragmentation of a crystal" (1979, p.25)

A von NEUMANN automaton would be self-reproducing as a whole in a limited sense only if, after a number of **operations** (through a **process** akin to an **hypercycle**), it would regenerate *itself*. The automaton would then comprise the whole cycle.

Otherwise self-reproduction would mean production of another automata of the same type, and eventually of many other ones.

It is however possibly a matter of **levels**. **Self-reproduction** of the **elements** (in the sense of cellular automata) could conceivably lead to the **self-reproduction** of the **complex system** (in the sense of **autopoiesis**)

P. GREUSSAY comments: "von NEUMANN thought that, with a convenient **programming** of some cellular surface, some group of **cells** with proper characteristics would be able ...to produce a copy of itself in another zone of the cellular surface, this copy being able in turn to do the same" (1988, p.1321)

To achieve his goal, von NEUMANN selected a complex **repertory** of 29 possible **states** combined with an intricate **transition function**.

"In 1968 Edgar CODD... discovered a universal constructor **configuration** whose cells are limited to 8 different **states**.

"In 1984 Christopher LANGTON (University of Michigan)...showed that a self-reproductive cellular automata does not necessarily need the intervention of a **cell configuration** endowed with the property of a **universal constructor**" (Ibid, p.1322).

In von NEUMANN, CODD and LANGTON's cellular automata "the **self-reproduction process** is actively directed by the **initial configuration** itself, through a **transition function**. Take an **initial configuration** at random and there is no more any **self-reproduction**. Thus such a **self-reproduction mechanism** requires a quite complex and substantially precise construction. Indeed, to endow the parent **structure** with the capacity to actively direct its own duplication, transcription devices of the "genet-

ic material" of the **initial configuration** are needed, as well as **translation** devices acting on the **environmental** cellular surface" (p.1322)

We are coming thus very close to **organizational closure** in **autopoiesis**.

This research promises to be highly significant for the logic of future complex computers and probably also for genetics.

0208

AUTOMATION⁵⁾

The use in **production** and in **control processes** of **machines** having the capacity to adjust to changing conditions

"The **adjustments** require "sense **receptors**" (which take readings from the **environment**), **communication networks**, stored **memory** of standard **states**, correction devices, etc. All of these make for greater **complexity**, since the **state** of each device is an additional **variable** in the **state** of the system" (A. RAPOPORT, 1966)

Automated **machines** tend thus to become **open systems**, more **autonomous** and more similar to **living systems**.

They are normally **integrated** within still more **complex systems**.

0209

AUTOMATON (Cellular)²⁾

1. An abstract device able to transform itself.

The **concept** of a cellular automaton has been developed by A. TURING (1950) and John von NEUMANN (1956) and also somehow by W. McCulloch and W. Pitts (Their **formal neuron model**)

F. HEYLIGHEN describes cellular automata as "... mathematical **models** of **distributed** dynamical **processes** characterized by a **discrete space** and **time**" (F. HEYLIGHEN, 1997, p.33)

The conditions for the construction of a cellular automaton are as follows:

- an unlimited and uniform **substrate**, which constitutes a perfectly **isotropic environment**
- identical **elements** or cells, with defined properties
- an **initial configuration**, consisting of a number of **cells**
- definite **rules of transformation**

The basic characteristic of cellular automata is the **emergence** of complex **organization** obtained from simple **rules**.

Numerous varieties of cellular automata have been proposed. The best known are those in CONWAY's **Game of Life**. However MARUYAMA has used one as early as 1963 as an example of "**deviation-amplifying mutual causal processes**".

As to the **rules of transformation**, some are not deductible from any previous **configuration** ("**Garden of Eden**")

In some cases the **rules of transformation** are themselves embedded within the **initial configuration**.

2. A **network** composed of **elements (nodes)**, each of whom is an elemental device able to perform some elemental calculation.

Every **element** of the cellular automaton may be considered itself an automaton if its **operation rules** are included. According to A.G. BAR-TO: "Cellular automata are **networks** of identical automata which are interconnected in a regular way with the automata having neighboring positions in the **network**" (1978, p.165)

B.R. GAINES and L.J. KOHOUT state: "...an automaton is a **discrete-time, discrete-state-space, state-determined machine**" (1976, p.192).

Each **element** processes a limited number of possible **binary states**.

The automaton evolves step by step, in a **discontinuous** way, according to the **rules** imposed to its **elements**, which determine at each step the **state** of each **node** according to its preceeding **state** and the **states** of the neighbouring **nodes**.

Curiously, a very complex global **behavior** may emerge from the application of quite simple **rules** at local level.

GAINES and KOHOUT state: "... neither the actual current **state** of an automaton nor its current **input** are necessarily well-defined. For example, we may know only the *probability distribution* of possible current **states**, or of possible current **inputs**. In either case the next **state** of the automaton will not be necessarily a single **state** but will probably also be known only as a **distribution**" (Ibid)

ASHBY has given interesting examples of such **ergodic systems**, whose **repertory** of all possible **states** is resumed in a **markovian matrix**. (1956)

According to GAINES and KOHOUT: "It is a convenient generalization of the **concept** of an automaton to consider **transitions** not just between **states** but between such **states distributions**, regarding **distributions** over **states** and **inputs** as generalized "states" and "inputs" respectively" (Ibid).

These authors propose the corresponding terminology of **hyperstates** and **hyperinputs**.

The automaton model is nowadays basic to the study of so-called **neural networks**, **connection machines** and **distributed artificial intelligence**.

It may even become very useful for the **description** of **social systems** in general.

0210

AUTOMATON (Finite)²⁾

A finite automaton is characterized by the following properties:

- an **initial state**
- a finite **set** of possible internal **states**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

- a next-state **function** allowing for **transitions** from one internal **state** some other one
- a **subset** of the **set** of internal **states**, whose elements are **selectors of inputs** (accepting states)

An elemental automaton is open to any acceptable **input** and must necessarily function as a **sequential machine**. It can be represented by a **graph**. (After F. HARARY and S. LIP-SCHUTZ, 1967)

However, according to J.von NEUMANN, as quoted by L. LÖFGREN: "... when an automaton is not very complicated, the **description** of the **functions** of that automaton is simpler than a **description** on the automaton itself but ... the situation is reversed with respect to complicated automata" (1977, p.211)

This is a result of the **simultaneous** interplay of various **rules**, which leads to **ergodicity** or **chaos**.

0211

AUTOMATON (Learning)¹⁾⁵⁾

A type of automaton made of several **subroutines** able to interact

An interesting example is R.A. Brooks's "Allen" robot, described as follows by M. Pesche (2000): "Allen does not "think" about the room it occupies: it makes no effort to build a **model** of the room it occupies: or to understand the shapes of the objects inside"(p. 29)

"Allen is thus not programmed, i.e. no precise prescriptive instructions guide its **behavior**. It does not respond to the general characteristics of so-called "Artificial intelligence". Pesche writes: "Allen is built with a tight **connection** between its **sensors**, which detect the presence of nearby **objects**, and its effectors, which move the **machine**..."

"...Allen does not follow a **routine** sequence of **programming** steps to generate its moves. Several modular **subroutines** - such as drives to avoid moving objects and to explore uncharted **territories** run simultaneously and independently, which causes them to interact in unpredictable ways as they respond to the **environment**.

"Neither of these independent **modules** begin operating with any **knowledge** about their **environment**, nor about how their **activity** affects this **environment**. But as the **modules** execute, they compete to generate some aspect of Allen's overall **response** to its **environment**"(Ibid)

This is quite similar to Rumelhart and McClelland **Parallel Distributed Processing** and it leads to a **bottom up** construction of a globally **coherent behavior**.

Interestingly, Pesche observes the similarity of Allen's **behavior** - as an automaton - with **learning** in children as was investigated by Jean Piaget, who described children's play as "...an advanced experiment in the ways the world works"(p. 30)

Both ways of learning lead to behavioral **autopoiesis**

0212

AUTONOMY^{1) - 3) - 4)}

The capacity of a system to select and decide, within **limits**, its own **behavior**.

This concept of autonomy was introduced by the French biologist P. VENDRYES (1942). It is quite different from MATURANA and VARELA's concept, introduced about 20 years later, but in no way incompatible. VENDRYES described a **hierarchy** of various **levels** of autonomy: trophic (or **metabolic**), kinetic (motor) and psychic and mental. This corresponds more or less with LABORIT's **hierarchic** concept of the **brain's organization**.(1954 and 1976). This concept of autonomy is essentially based on the relative possibility of the system to **control** its **relations** with its **environment**. It also implies a specific **concept of time**: present **time** is the **connection** between an already strictly determined past and a still more or less probabilistic future offering yet possibilities to select between various **choices**. Such **selection** converts one - and only one - of these options into reality, suppressing all the others. This **concept** thus implies a **limited** probabilistic view of the future, quite consonant with the more recent concept of **chaos**.

In the same vein, K. BERRIEN observed "1) **Choice** is the human equivalent of probabilistic **outputs** in the more general **systems theory**" and "2) Although some of the determining **parameters** (can be specified), their precise **measurement** is subject in principle to an **uncertainty** of the same general kind as originally indicated by HEISENBERG" (1968, p.97)

VENDRYES theory describes as follows the **goals**, **means** and **mechanisms** that characterize autonomous systems:

- **Counter-randomness**: The system uses regulating devices to compatibilize **random inputs** with its internal **determinism**;
- Internal **determinism**: The system is able to maintain the **fluctuations** of its internal **processes** within stable **limits**. This connects VENDRYES' views with CANNON's **homeostasis** and with MATURANA's **autopoiesis**;

- **Interrelation functions**: The system possesses mediating **functions** that coordinates its internal **states** with the **environmental** variations;

- Internal **medium** ("**invironment**"): This is the internal **space** of the system, where the **interrelations** between the **subsystems** take place. This concept comes from Cl. BERNARD and connects VENDRYES autonomy with J. MILLER's **living systems**, and again with CANNON's **homeostasis**, also inspired from Cl. BERNARD.

- **Perturbation**: Any **input** not yet controlled by the system. However, many **inputs** are needed by the system, and their **assimilation** is an essential aspect of the system's **symbiosis** with its **environment**.

- **Random relation**: Any not pre-defined **interrelation** of the system's **inputs** with its internal **states**. VENDRYES explains that the **relations** between two systems are **deterministic** when already functionally linked and **random** when not linked. The system may gain - up to a point and with **time** - predefined **controls** on critical **inputs**. This is another link with **autopoiesis**.

- **Articular relation**: A **mechanism** which permits the **selection** at any moment of a position, **state** or motion among various that are possible. The **model of articular relation** has been widely developed by VENDRYES. (see specific heading)

- **Reserve**: A potentially usable **store of energy** or **matter** within the system, that can be used at any moment by the corresponding **control** to offset in real **time** or within a **time lag**, a specific **perturbation**. This is a need in order to maintain the system distinct from its **environment**. **Controls** are efficient only if associated with specific **reserves**. (see specific heading)

Another viewpoint is given according to a subtle definition by R.H. HOWE: "Autonomy is the unity of computation and construction" (1975, p.5)

In this case, computation should be understood as that type of computation which occurs in concrete **neural networks** (i.e. any system with internal **communication** between numerous **elements** in an **organizational closure** way), and construction as **self-reproduction**.

In the last resort, it must however be emphasized that a system's autonomy depends always of its possibility to obtain sufficient **energy inputs** from its **environment**. In A.S. IBERALL words "... an autonomous system is a thermodynamic engine" (1973, p.4)

This basic condition, the existence of an **organizationally closed set of rules** being also provided for, allows for the autonomous existence of the system.

Still more generally, more autonomy also means more **interdependence** among more **components** and **subsystems** within the system and more extended and complex relations with a more precisely specified **environment**. Man for example, needs many more specific types of **inputs** than a tree.

0213

AUTONOMY BY AUTOPOIESIS^{1) - 3)}

"Attribute of an **organizationally closed system**, i.e. a system whose **organization** is self-explanatory and, by implication, circular" (K. KRIPPENDORFF, 1986, p.5)

Autonomy in MATURANA and VARELA's sense is self-generated through an **organizational closure process**. In R.N. ADAMS words: "...control over relations of production is wholly internal" (1988, p.63).

This is a property of **living systems**. H.von FOERSTER writes: "By autonomy we mean that all **decisions** regarding an **organism's action** are made within its skin. A living **organism** is a **universe** in itself". von FOERSTER proceeds, giving the following example:

"1. The **interpretations** of an **organism's** sensations determine its **activity**;

"2. An **organism's activity** determines the interpretations of its sensations" (1981, p.215)

He resumed his stand in these terms: "A living **organism** is an independent, autonomous and **organizationally closed** being" (1992, p. 42). By "independent" (in the German text "selbständig", i.e. "existing by itself"), one should understand "**entficated**" in R. GERARD sense.

von FOERSTER also stated that autonomy is "**self-regulation**" or "**regulation of regulation**" (1981, p.306), which locates him quite close to VENDRYES.

P. GÓMEZ and G.J.B. PROBST, in turn, write:

"1. The development and **viability** of a system depend much more on internal **coherences** than on **environmental inputs**. What is important is what the system does, how it acts, and finally, how it reacts to **noise** from the **environment**

"2. An autonomous system produces its **limits** and the **limits** define the system. Research should emphasize the search for **sources** and **rules** of the internal **transformations** of **coherences**" (1989, p.314)

The first statement could be somewhat misleading. No system can emerge, develop and maintain itself if the necessary **inputs** are not available in the **environment**. Only the *pre-adapted* systems are viable. Of course, **pre-adaptation** is a result of **autopoietic transmission** of formerly **emerged** conditions. As an example, an astronaut is viable in space only if the basic **environment** he/she imperatively needs for **survival** is artificially recreated and maintained.

Autonomy itself is obtained only within the specifications of an inherited or formerly **emerged template**.

→ **Archetype**

0214

AUTONOMY: the 3 basic levels ¹⁾

J. LORIGNY writes: "According to P. VENDRYES three levels of autonomy should be distinguished: metabolic autonomy, motor autonomy and mental autonomy...

"VENDRYES's three autonomies correspond to three successive stages in **evolution**. Each developed at a definite stage of life's history and does not emerge formerly, at least in a visible fashion... The more recent ones are imbricated into the former ones, each using them after incorporating them...

"Thus, **motor** autonomy uses **metabolic** autonomy... and in the same way, mental autonomy uses **motor** autonomy... (Furthermore) each autonomy feeds and reinforces the former ones, having them **embedded** in a systemic **hierarchy**" (1992, p.13).

Strikingly enough, when compared with MATURANA and VARELA's concept of **autonomy** and **organizational closure**, VENDRYES himself wrote as early as 1942: "The living being is to itself its own **reference system**" (1942, p.290).

0215

AUTOPOIESIS ^{1) - 2)}

The condition of a system able to regenerate itself by **self-reproduction** of its own **elements** and of the **network** of their characteristic interactions.

This notion has been introduced by H. MATURANA, who writes: "... there are systems that are defined as unities as **networks** of production of **components** that 1) **recursively**, through their **interactions**, generate and realize the **network** that produces them; and 2) constitute, in the **space** in which they exist, the **boundaries** of this **network** as **components** that participate in the realization of the **network**" (1981, p.21).

The main characteristic of autopoietic systems is **organizational closure**.

Autopoiesis has very important bearings on the theories of **perception** and of **cognition**. As stated by W.R. WINBURN: "The perspective of autopoiesis, in which **organisms** are described "from the inside out", proposes a basic shift in the **observer-object relationship** behind traditional scientific **observation**. **Living systems** are explained only by **reference** to features within the possible **domain of interactions** specified by their **organization**" (1991, p.565).

One wonders however what WINBURN really means when he writes: "But autopoiesis defines biological **autonomy** in terms of **self-referential organization** of **living systems**. From this vantage point, **organisms** are necessarily **input-less** and **closed**" (Ibid). This seems to be unfortunate semantics (more than once to be found in autopoietic literature): any **living system** depends on **inputs**, a lot of them. That these **inputs** be assimilated by **organisms** in a way non-contradictory to their internal **self-referential organization** is a different point, related to that kind of systemic stabilized **identity** obtained through autopoiesis.

R. ROSEN's formulation seems better: "... a non-empty **environment** can only affect **autonomous system behavior**, never its **autonomous dynamics** or **identity**" (1993, p.27). Even so, any system can be destroyed by its **environment**.

From another viewpoint, autopoiesis seems to be constructed in a **hierarchical** way. Biological and even possibly biochemical autopoiesis in individuals and species alike, must have preceded physiological, psychological, mental and social autopoiesis. Each of these successive **levels** is a kind of stepping-stone for the next **emergent** more complex one. This could be the connection between higher **level order**, **emergence** by **dissipative structuration** and, most importantly, **nucleation** from one side, and successive **levels** of **organizational closure**, from the other.

F. CAPRA gives the following wide embracing significance of autopoiesis: "...the **pattern** of life (that is the **pattern** of **organization** of **living systems**, **dissipative structure**, as defined by Prigogine, as the structure of living systems; and **cognition** as defined initially by G. BATESON (1904-1980) and more fully by MATURANA and VARELA (1946-2001), as the process of life (1977, p. 160)

→ **Autogenesis; Epigenesis; Equipotentiality; Santiago theory; Zero-system**

0216

AUTOPOIESIS: About LUHMANN's view ⁴⁾

O. THYSSEN (1995, P. 13) characterizes as follows the way LUHMANN (1927-1998) extends the concept of autopoiesis: "LUHMANN generalizes the concept to cover not only **living systems**, but also mental and **social systems**. Whereas **living systems** operate in the medium "life", mental systems operate in the medium "**consciousness**" and **social systems** in the medium "**communication**". According to LUHMANN, a **social system** does not consist of human beings or **artifacts**. It consists of an ongoing stream of **communication**". THYSSEN has some problems with these views: "An **autopoietic system** is closed"(Note: i.e. *organizationally closed*) "It has no contact with the **environment**"(Note: it is however *structurally coupled* with it. Is that not a "contact"?). THYSSEN adds: "A disturbing consequence is that mental and **social systems** are totally distinct. No analysis of **consciousness** will ever reveal anything about **brain processes**, which are the domain of **living systems**"

One wonder if it is not the reverse: could not **brain processes** reveal something about **consciousness**. And: "Another disturbing consequence is that LUHMANN has no place for the individual. This point is methodological, not normative or "antihumanistic".(Ibid)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

MAN is a very diffuse idea allowing references to many different systems which do not have MAN as an **element** and which do not form a unity: no **supersystem** encompasses living, mental and **social systems**. So what is MAN depends on who is observing and how. KORZYBSKI (1879-1950) could have said it: MAN is a high level abstract "**label**" that should be used very carefully.

The hinge of the problem is obviously that any **social system** depends on *individual observers* in two complementary ways:

- 1- In any **activity** the **structural coupling** with the **environment** of the **social system** is through individuals (which make a kind of porous frontier with the **environment**)
- 2- The internal **autopoietic behavior** of the system as a **whole** depends on myriads of interindividual **structural couplings** as **observers** of each others

0217

AUTOPOIESIS and EVOLUTION^{1) - 4)}

The concepts of **autopoiesis** and **evolution** are difficult to connect in a satisfactory way. Various critical angles must be considered.

1) **The autopoiesis of individuals:** **Autopoiesis** seems to preclude any acquisition of new characters by individuals, as it implies **organizational closure**. Such is at least the case *immediately after the creation of a new individual*. However, impacts from the **environment** may still be received, which will potentially modify some characters, in very exceptional cases transmissible to the descendants. If otherwise, no **evolution** (nor genetic engineering) should be possible.

2) **Variability of a population:** Genetic recombination allows **populations variability**, but then only within the **limits** of the global genetic stock in existence. However, this stock may have been potentially impoverished or, on the contrary increased by the effects of inheritance by some individuals of mutations undergone under impacts from the **environment**, received by individuals of a former generation.

3) **Effects of mutations:** Lethal mutations are those which destroy the **viability** of new individuals for not being compatible with their basic **control subsystem**. Acceptable ones are those compatible with the **constraints** proper to the species and, as such, "written" in the **control subsystem** of the individuals (See the concept of "**Stellar system**" of A. MALINOWSKY).

4) **Radiative evolution:** If acceptable mutations are to become registered within the **control subsystem** and in accordance with the already existing **constraints** proper to the species, then every species may become the origin of a wide variety of new species. However, as the species **control subsystem** (partially represented in every individual) is **autopoietic** (i.e. **organizationally closed**), it will never – at

least in natural conditions – be possible, starting from the present type, to regress to former types.

5) **Mega-innovation by association:** It seems that, at some very infrequent times in the **process of evolution**, the **association** of numerous similar individuals, grouped within different functional units, produced the **emergence of heterogeneous systems** of a higher degree of **complexity**. In such systems a higher order central **control subsystem** is needed and it seems to surge spontaneously (i.e., through a **process** still not yet quite well understood). The present global **transformation** of mankind into a hypercomplex global system is, possibly, an example.

0218

AUTOPOIESIS and the "IMMANENT QUESTION"³⁾

The concept of "immanent question" has been introduced by G. BATESON in "Steps to an Ecology of Mind". (1973, p.371)

However the first example given by him comes from biology: "Consider the case of the unfertilized frog's egg for which the entry point of the spermatozoon defines the plan of bilateral **symmetry** of the future embryo.... The prick of a hair from a camel's-hair brush can be substituted and still carry the same **message**... But the internal **context** into which the **message** comes must be exceedingly complex. The unfertilized egg, then, embodies an immanent question to which the entry point of spermatozoon provides an answer" (Ibid).

This implies that the egg, the seed or, probably, the **brain** and even possibly the first germ of a culture, contains (in BATESON's words) an appropriate **structure**, i.e. the implicit **time-to-talized order** created from former **adaptation** and **evolution**. (see "order from noise", for a critique of the well known von FOERSTER's experience with magnets).

Autopoiesis seems thus to be the result of a **process** of progressive **emergence of order**, as the source of BATESON's "immanent question".

Remains to find out which is the prime mover of this **emergence**.

→ **Autogenetic system precursor; Zero-system**

0219

AUTOPOIESIS (S. BEER on levels of)^{1) - 2) - 4)}

In his paper on "Suprahuman Autopoietic Systems", F. ROBB explains in the following way BEER's views on **emergent levels of autopoiesis**

"Beer (1975) in specifying the conditions of **viability** of systems, conceptualizes the social world as containing "esoteric boxes" which, when strung together, form larger **organiza-**

tions. These esoteric boxes are not **closed systems** but they are more often than not **ultrastable**, resistant to **change**, and are "designed for **survival**". The **connections** between these **subsystems** are complex beyond **understanding**, transient, and **unstable**. It is the **networks of connections** that are dubbed "**metasystems**", and effective **control** over the assemblage can be achieved only if these **metasystems** can be defined and formalized, or as Beer puts it, "institutionalized". The design of a **metasystem** required to ensure an **organization's viability** entails that it should be capable of absorbing the **variety** generated by its lower-order systems and by the **environment of the whole**.

"The **metasystem** uses a higher-level logic and higher-order values than used by the **object systems** and these are the means of containing **variety** and of realigning the **objectives** of the esoteric boxes so that they serve higher-order **objectives**. Left to themselves, the **subsystems** will **suboptimize** and will not contribute to anything but their own **survival**. In any social **organization** there may be many **levels of recursion**.

"Beer's esoteric boxes appear to have all the properties of **autopoietic** systems. They are **processors** of self-production. They appear to be, before intervention **organizationally closed**. The institutionalization of their **metasystems**, which Beer calls for, may be seen as the attempt to open them so that their **autopoiesis** is destroyed and their **processes** directed toward the **autopoiesis** of the greater **whole**.

"To Beer, the intervention is made in order to understand internal **structure** and **behavior** and to redesign the **metasystemic** relations required if the **autopoiesis** of the **whole** is to be sustained. In this way, the "designed" **metasystem** is seen as a necessary artefact required to ensure that the **whole** satisfies the needs as expressed by the **objectives** of the highest (in logical order) **level**. Without this intervention the lower-order needs may be satisfied temporarily but at the very great risk that the **metasystemic** interconnections will be severed or dissolve as the **whole** disintegrates" (1989, p.59)

It should be pointed out that:

1- **Subsystems' autopoiesis** is probably not "destroyed", but more or less **embedded** and modified according to the autopoietic needs of the **whole**.

2- The **autopoiesis in levels** concept could likely be applied to all **levels of complexity**, starting possibly with the atom and the molecule.

3- Referring to "Suprahuman Autopoietic Systems", Robb himself emphasized that it is in no way obvious that social **metasystems** can be widely controlled by individuals. The opposite is quite more probable.

4- Beer's well known attempts to create global **monitoring** systems at the national **level** in various latin-american countries (Chile, Uruguay, Venezuela) may even seem somewhat paradoxical, knowing his own skepticism about the "surrogate worlds we manage" (1973).

0220

AUTOPOIETIC RELATIONS OF PRODUCTION^{1) - 2)}

In MATURANA and VARELA view, autopoietic systems count with an inherent **set of relations of self-reproduction**, i.e.

1. "The **relations** of constitution "that determine the **components** produced, constitute the **topology** in which the autopoiesis is realized"
2. The **relations of specificity** "that determine that the **components** produced be specific ones defined by their participation in the autopoiesis"
3. The **relations of order** "that determine that the concatenation of the **components** in the **relation** of specification, constitution and **order** be the ones specified by the autopoiesis" (1980, p.88 – as quoted by R.N. ADAMS, 1988, p.82).

0221

AUTOPOIETIC SYSTEM^{2) - 3) - 4)}

"A unity realized through a closed **organization** of production **processes** such that (a) The same **organization of processes** is generated through the **interaction** of their own products (**components**) and (b) a **topological boundary** emerges as a result of the same constitutive **process**" (M. ZELNY, 1981, p.6).

ZELNY comments his definition as follows: "... the **organization of components and component-producing processes** is maintained **invariant** through the **interactions** and **flux of components**" (ibid.).

F. ROBB thus resumes MATURANA's basic **concept**: "Autopoietic systems are characterized by circular **relations** which give rise to and maintain their autopoiesis. They define themselves, they are irreducible **objects** in nature, not defined by **observers**, they are self-producing and self-maintaining, they emerge from **instabilities**, and they have properties not possessed by their **components**" (1990, p.394).

The comment about "irreducible **objects** of nature" is intriguing: it could possibly be considered as a base for a systemic **ontology**.

However, when H. MATURANA and F. VARELA write: "**Living systems**, as physical autopoietic **machines**, are purposeless systems" (1980, p.86), one wonders if there may be a danger that some could interpret autopoietic **machines** as solipsistic (or autistic!) **machines**.

Seemingly, an autopoietic **observer**, for instance, must, to begin with, **construct** his/her internal **organizational closure**, even if this **process** begins before birth, in the guise of physiological **organizational closure** through genetic and **generative** heredity.

As conjectured by ZELNY, any autopoietic system would need to be a society, whether of **cells** in a **living system**, ants in an anthill, neurons in the **brain**, human beings in an **organization**, and even possibly in a near future elemental **robots** in systems of **distributed artificial intelligence**.

It has also be argued, by F. ROBB, that: "... there are strong reasons to believe that ever-higher order social **processes** can **emerge**" (1990, p.394).

Biotopes as well may be considered up to a point as autopoietic systems, when not seriously disturbed by outside **perturbations**.

Amanda GREGORY states: "The autopoietic system is structurally coupled to its **environment**: it responds to environmental **perturbations** by producing a feasible **set of responses**, in such a way to maintain its autopoietic **state**, from which the **environment** selects" (1996, p.571)

Thus the autopoietic system is equipped to oppose a strong resistance to **change**.

Accordingly, A. GREGORY examines in her paper the difficult relation between external evaluators and the (internal) managers of human **organizations**, which autopoietic character at times leads them to be highly resistant to **change**.

0222

AVAILABILITY¹⁾

Existence in the **environment** of the **resources** needed by the system.

Availability must be permanent or, at least, exist at any moment the system is seeking the **resources** it needs.

This is a condition of **survival** for any system, even if the normal **input source** can be in some cases replaced, at least temporary, by an alternative more or less equivalent **source**, or by **reserves** stored within the system itself.

Availability can be affected by variations in the **environment**, spontaneous or provoked by the system's own **action** or by **competition** between various systems.

0223

AVALANCHE²⁾

A very quick succession of **changes** triggered by a minimal **perturbation**, in a **network** or a **composite system** in a **critical state**.

An avalanche is a **percolation phenomenon** and is submitted to a **power law distribution**.

According to P. BAK and K. CHEN: "An avalanche is a type of chain reaction or **branching process**" (1991, p.28). Good examples are the propagation of an earthquake, of a forest fire or of a mud or snow slide.

In **composite systems**, the possibilities that such avalanches could propagate, depend on the characteristics of the **network** and, particularly on the existence of more or less extended stable "islands". (Blocks of **frozen elements** as described by St. KAUFFMAN, 1993, p.67)

Avalanches imply the existence of conditional **interactions** between **elements** in a more or less loose **network**.

P. BAK writes: "Large avalanches, not gradual **change**, make the link between quantitative and qualitative **behavior**, and form the basis for **emergent phenomena**" (1996, p. 32)

This is significant not only for physical **phenomena**, but also for economic and sociological ones: "If this picture is correct for the real world, then we must accept **instability** and **catastrophes** as inevitable in biology, **history** and **economics**" (ibid).

History here covers political and social upheavals.

And: "Because the outcome is **contingent** upon specific minor **events** in the past, we must also abandon any idea of detailed long-term **determinism** or **predictability**" (ibid).

This does not however seems to be **absolute**: "detailed" defines the basic meaning of this sentence. We still have a kind of overall **long-term stochastic determinism**, related to **self-organized criticality**. Earthquakes for instance are frequent along some known geological fracture lines, and rare elsewhere. In **time**, their **frequency** is relatively defined by a specific **power law** (Gutenberg- Richter Law) (ibid, p.13)

0224

AWARE OF¹⁾⁵⁾

It is significant that the word "aware" is generally used with "of".

Obviously awareness is always the result of some relation between a percipient **observer** and some **event** or **situation** in his **environment**.

The crux of the matter is finding out how exactly such **interactions** take place, which consequences they produce and which more precise **meaning** we can give them after a cautious critical evaluation

0225

AWARENESS¹⁾⁵⁾

The awakening of alertness and attention triggered by any specific **perception**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Awareness is frequently used as a synonym for **consciousness**. This seems to be rather unfortunate, as **consciousness** is the ultimate state of awareness, if used in the **meaning** of a capacity to reflect on one's own **perceptions**, as integrated and more or less clearly formulated by a human **brain**.

However, as expressed by F. Capra, this is "a key character of human **consciousness**". Thus "for a thorough understanding of the general **process of cognition in living systems** it is thus important to understand how human **consciousness**, with its abstract thought and symbolic concepts, arises out of the **cognitive process** that is common to all living **organisms**" (1997, p. 286)

In fact, awareness in its first state, can be only minimally distant from non-awareness. An example could be the passage from a merely dim **perception** of cold weather to a much clearer perception of what it means for the **observer**: 1) "It feels very cold. 2) Let me have a look on the thermometer for a more precise **evaluation**"

Awareness leads to focused attention and normally to a more selective orientation of **perception**, that may in last resort become clearly **intentional**. This sequence can already be observed in animals like dogs or chimpanzees

In many cases it leads to specific **action** and is thus a prime mover of selective **behavior**.

0226

AWARENESS (Critical) ¹⁾²⁾³⁾

Awareness is a very ambiguous notion. Everybody believes being "aware". But the fact is that there are many different forms and qualities of awareness. Critical awareness is widely discussed by M. JACKSON in his most recent book (2000, p. 356), as a basic foundation for **systems thinking** in general.

JACKSON basically distinguishes a hard **approach** and a soft one to complex **situations** and **issues**. He quotes CHECKLAND's opinion that "hard systems thinking is guided by functionalist **assumptions**: the world is seen as made of systems that can be studied objectively and that have identifiable **purposes**" (Ibid).

Leaving aside the "observing systems" problem (von FOERSTER, 1981), the most favored tool of hard system thinking will be **linear causality** or, at most, a kind of cybernetical **mechanicism**. In short, the quality of awareness depends on the **range** and quality of **perception** and on the limits of our conceptual **frame of references**.

JACKSON commends a wider sociological approach to the awareness problem: "with CHURCHMAN, ACKOFF and CHECKLAND, systems thinking becomes much more subjective, and the emphasis shifts from attempting to model systems "out there" in the world toward using **systems models** to capture possible

perceptions of the world". Furthermore this leads to "structure and enhance debate among **stakeholders**" so that an **accommodation** about **action** to be taken can emerge" (Ibid)

In short, critical awareness should be kind of stereoscopic or **holographic**. This view should meet JACKSON's conclusion: "Critical awareness, incorporating social awareness, became one of the central principles of critical systems thinking and remains so to this day. The main problem, of course, is that the apparent strengths and weaknesses of any particular systems approach will vary dramatically depending upon the **paradigm** from which it is observed and judged" (Ibid., p. 357). And moreover: "Critical awareness involves... criticizing the theoretical underpinnings, strengths and weaknesses of available systems **methodologies** and the usefulness of the **variety** of systems models, **methods**, **tools** and techniques in the service of different methodologies" (Ibid, p. 375)

0227

AWARENESS (Levels of) ¹⁾⁵⁾

Levels of awareness seem to be depending on the growing **levels of complexity** of the **nervous system** and the **brain** all along the evolutive lines of animal species

It has much to do with the **activity** chain that starts with **perception**, follows with **perception** interpreted as a **signal**, and ends with some **behavior** triggered by the **signal**

The following **levels of awareness** should be tentatively considered:

- **perception** (in all cases the basic condition for any awareness)
- inner **interpretation** of perception as a "**signal**" (this already supposes a previous training)

The capacity of **interpretation** broadens, widens and deepens until it reaches the aptitude for finer and finer **distinctions** in **categorization** and, finally, more and more capacity for complex **abstraction** and self reflecting **representation**.

- enhanced individual awareness obtained through reciprocal signaling within social **frames**. Such frames also become ever more complex from social amoeba to human societies
- the possibly questionable level of collective awareness in societies and **cultures**

Archaic forms of such collective awareness can be observed in beehives, termites mounds and ants nests.

0228

AWARENESS (Self) ¹⁾⁵⁾

The capacity to clearly perceive oneself as a separate entity

As noted by F. Capra, self-awareness, as far as we know, is manifest only in higher animals and fully unfolds in the human mind" (1997, p. 287)

He adds: "As humans we are not only aware of our **environment**, we are also aware of ourselves and our inner world. In other words, we are aware that we are aware. We not only know; we also know that we know. It is this special faculty of self-awareness that I refer to when I use the term "**consciousness**" (Ibid)

It can also easily be observed that the degree of self-awareness varies widely among human individuals, from about non-existent to acute **consciousness** in the case of mystics, "illuminated" or "awakened" (in the Buddhist sense) Capra also observes that "In the **Santiago theory**, self-awareness is viewed as being tied closely to **language** and the **understanding of language** (as) approached through a careful analysis of **communication**"...and "**Communication**, according to Maturana, is not a **transmission of information**, but rather a **coordination of behavior** among living **organisms** through mutual **structural coupling**. Such mutual **coordination of behavior** is the key characteristic of **communication** for all living **organisms**, with or without **nervous system**, and it becomes more and more subtle and elaborate with **nervous system** of increased **complexity**" (Ibid)

→ **Brain** (Triune)

0229

AWARENESS vs. CONSCIOUSNESS ³⁾⁴⁾

According to Susan Blakemore, awareness is a moment-to-moment **phenomenon** (2002, p. 26).

It is the result of instantaneous **perception**, that can be repetitive, but in a **discontinuous** manner.

Moreover awareness is always awareness of "something". It necessarily supposes an **experience** of some **event** "there outside". But the experience is "inside" as it is basically a complex **computation process** in a **neural network**.

It is also automatic. We do not need to decide that we are going to perceive: we just do.

As our **nervous system** possesses somehow the faculty of remembering former **experiences** we easily gain the impression of a **continuity of consciousness**. In fact it seems that this is also a construction in our **nervous system** which somehow throws bridges between these **discontinuous** moments of awareness.

The nature of the bridges is probably related to the continuous existence of a neuronal net in our **brain**, which becomes repeatedly reorganized after each **experience**. This is the gist of Maturana and Varela concept of **Autopoiesis**. (- see J. Gran, 2002, p. 46-49)

→ **Hippocampus**

0230

AXIOLOGICAL HYPOTHESES versus AXIOMS³⁾

J.W. SUTHERLAND says that the negation of POPPER's caveat about embracing creeds, "transforms axiological hypotheses into axioms" ... in which case "...the role of the scientist is displaced by that of the rethorician" (1973, p.107).

Since most, if not all of the **General Systems models**, are patently axiological hypotheses, **generalists** should be careful not to fall in the trap signaled by POPPER.

0231

AXIOLOGY³⁾

The discipline that studies the nature of **values**.

Systemics has an impact of axiology mainly for the following reasons:

- As it instates a **hierarchy** of **embedded** and **interdependent** systems, it should lead to a re-examination of the **rights**, **responsibilities** or reciprocal **needs** of each system and **co-system** within the corresponding **supra-** and **infrasystems**. This subject embraces a wide range of disciplines, from ecology to psychology and sociology.
- As it introduces a strong **time-dimension**, **needs**, **rights** and **responsibilities** must be considered within a future perspective, corresponding to different **time scales**.
- As it proposes a specific way to understand the relation of the **observer** with the observed, and peculiarly, the relations among various **observers**, systemic axiology needs to focus on **consensus** and **co-participative decision making**.
- As systemics introduces a new **understanding** of the nature of cultural differences, systemic axiology must also strive to find satisfactory transcultural **values**.

B

0232

BABEL TOWER EFFECT¹⁾

The growing incommunication between specialists of all trade resulting from increasingly partialized specialization.

While specialization is the condition of **efficiency** and genuine well founded **knowledge** in every specific trade, it also provokes a growing disconnection between specialists, as a result of the **emergence** of specialized jargons.

Systemics tries to create **meta-concepts** and a **metalanguage** of **isomorphic** or **homomorphic models** whose **validity** should cover as wide specialized areas as possible. It does not intend in any way to replace or reinvent specialized **knowledge**. Its real main aim is to

reestablish a higher degree of reciprocal **understanding**, in particular when numerous specialists must collaborate in the **management** of a complex **situation** or the **co-participative design** of some project.

0233

BACKGROUND¹⁾

The significant **environment**, past and/or present, of a **percept**, **representation** or **concept**.

The background is not taken into account until, for some reason, it becomes modified in a way that affects the **observer**. This is the case, for instance, of normal gravitation... until there is an earthquake, or for an astronaut floating in outer space.

However, a unperceived part of the background can be significant: nuclear irradiation can kill without being perceived.

The background can also silently accumulate slow **changes** that may suddenly **trigger** some **catastrophic effect**.

From a systemic viewpoint, an unobstrusive **monitoring** of the background can thus be very useful.

→ **Invisibility**

0234

BACKSIDE BALANCE⁴⁾

A kind of **behavioral feedback** that tends to restore dynamic **equilibrium** in a distorted economic or social relation.

Figure: see entry **BAKER's TRANSFORMATION**

The Baker's transformation as applied to Smale's "horseshoe"

From I. EKELAND: 1984, p. 90.

The notion has been introduced by M. MARUYAMA (1994, p.35), who calls it "backside system". It seems better here to avoid the use of the word system, because the backside **reaction** is not in itself a system, but a device or **process** within a system.

MARUYAMA gives various examples of this kind of **adaptive regulation** in distorted systems. "The combination of low wage and off-the-job income in South America, and low wage and multiple employment in Hungary until 1992, are also examples..." (Ibid)

MARUYAMA makes this very important observation: "Quite often, the backside system is invisible to outsiders" (Ibid)

0235

BAKER's TRANSFORMATION²⁾

A **topological** transformation which helps to visualize the **chaotic fractalization** of **processes trajectories** in **complex systems**.

I. PRIGOGINE and Y. ELSKENS describe the Baker transformation of a unit square as "a piecewise **linear area-preserving mapping**" (1986, p.211)

PRIGOGINE describes it as follows: "(it) owes its name to the association with the kneading of dough... Beginning with a square, we first flatten it into a rectangle. Then we fold one half of the rectangle on top of the other half to form a square again. This set of **operations**... may be repeated as many times as one likes. Each time the surface of the square is broken up and redistributed. The square here corresponds to the **phase space**. The baker transformation takes each point from its original positions to a new, but perfectly well defined position... Al-

though the series of points obtained in this way is "**deterministic**", the system displays in addition some irreducibly statistical aspects" (1980, p.77).

As explained by J. CASTI: "The stretching and folding operations are complementary, in the sense that the first separates points, while the second tries to bring them back together again – but with new neighbors" (1994, p.91).

He adds: "There are two directions in which the points can move: up/down and left/right. So there are two rates of separation, one in the vertical direction, the other in the horizontal" (p.100).

The baker's transformation is a **model** of how a **deterministic process** can produce a **chaotic behavior**.

see figure page before

0236

BALDWIN Effect ²⁾

D. DEPEW writes: "The general idea of the Baldwin effect is that learned **behaviors** can affect both the direction and the speed of evolutionary **change**. If an **organism** changes during its lifetime to acquire **habits** or exhibit behaviors which permit more effective **interaction** with its **environment**...it will probably leave more offspring" (2000, p. 7)

In this way a connection is established between **ethology** (and even **ecology**) and **evolution**. The idea reminds also somehow of LA-MARCK's view about "heredity of acquired characteristics". In relation to DARWIN's view of evolution, it adds sense to the concept of **selection**.

Baldwin's idea, according to DEPEW is in need of "the articulation of new theoretical **frameworks** in which it may make sense" (ibid)

More generally, it is obviously related to the ways adaptive or evolutive change in **elements** or individuals affects the group of the **social system**. In **modeling** terms, it would be the reconstruction of the "**metasystem**" from **bottom up**, or the subtle contradictions and complementarities between **autopoiesis** (Maturana), **homeostasis** (Cannon), **emergence** (Priogine), **autogenesis** (Csanyi) and **variety** (Ashby).

No doubt: the debate is far from concluded. But the collection of papers published by "Cybernetics and Human Knowing" is a quite significant step. (7(1), 2000)

→ **Renormalization group; Somatic ecology**

0237

BASE RATE ¹⁾²⁾

The general **probability** of an **event** to occur.

Such a rate is more easy to determine for frequent **events**, as for example the occurrence of rainy or snowy days in New York, than for rare **events** as for example hurricanes in Miami.

0238

BASE RATE EFFECT ²⁾

"The effect that the **chances** of an **event** occurring at all - its base rate - have on our ability to predict it" (R. MATTHEWS, 1997, p.25)

The more infrequent an **event**, the less we can predict its occurrence.

This has practical consequences. MATTHEWS states: "Its central lesson - that rare **events** are hard to predict - could... save us from spending millions on what may well be scientific wild goose chase". As a possible example, the author gives the prediction of earthquakes, a costly research until now "without a single unequivocal success" (p.31).

Criticality theory helps to understand the deeper reasons of such failures.

0239

BASELINE ¹⁾

Existing conditions and **trends** in the **activity** of a system before any modifying **action** occurs.

It constitutes a bench mark **state** from which **knowledge** is needed for the **evaluation** of any natural or projected purposeful **change**.

It is also useful for consideration of non-action alternative

0240

BASIN BOUNDARY ^{1) - 2)}

The **set** of points that defines the outer **limit** of a **basin of attraction**.

The crossing of this boundary due to some **perturbation** knocks the system out of the basin and either sends it into some other basin corresponding to another **attractor** or readily destroys it.

However, according to R. THOM, the basins relative to two **attractors** can penetrate each other in a **topologically** complicated way, with a quite undeterminate outcome (1972).

See **Basin erosion**

0241

BASIN BOUNDARY (Fractal) ²⁾

The boundary of a **fractal basin of attraction**.

Nonlinear systems have in many cases **trajectories** submitted to **chaotic attractors**, which can be very complex, i.e. they may have a very wispy micro **self-similar structure** (homoclinic tangles; SMALE's horseshoe, etc...).

Such systems are very difficult to describe, to monitor and to control.

0242

BASIN EROSION ²⁾

The progressive invasion of a stable **basin of attraction** by **instabilities** generated by a **chaotic attractor**.

During this **process** the basin is progressively divided into layers of smaller and smaller **regions of stability** and of **instability**, i.e. becomes **fractalized**.

In such a case, the basin may become "... so thin or wispy that small **disturbances** can knock the system out of the basin to **converge** somewhere else" (A. McROBIE & M. THOMPSON, 1990, p.45).

These authors add: "To be safe any engineering system must have its **attractor** at a prudent distance from its **basin boundary**. Structural engineers refer to failure as "exceedance of the ultimate **limit stage**". Once a **structure** passes this condition, it will **collapse**" (ibid.)

This quite insidious **process** of loss of **stability** is responsible for numerous structural disasters in buildings, ships, airplanes, bridges, etc. submitted to external **disturbances** like winds, **overload**, collisions, small seismic movements, etc...

It is also present in celestial mechanics, where H. POINCARÉ first met it in the study of Saturn rings.

0243

BASIN OF ATTRACTION ^{1) - 2)}

The **region** that includes all the **trajectories** corresponding to an **attractor** in a system's **dynamics**.

A specific basin corresponds to each **attractor**.

The global **state space** consists of a **set** of **basins**, that are isolated from each other by **separatrices**. In the neighborhood of a **saddle**, basins **limits** become **unstable**, and a **trajectory** can jump from one basin to another (A **catastrophe event**).

This abstract concept can be intuitively visualized through the example of a river basin, in which **flows** circulate in a structured **space**. The general character of a basin implies, in K. KRIPPENDORFF's words: "... that no **state** in one basin succeeds or is succeeded by **states** in another basin and any two **states** in one basin share at least one preceeding **state** or successor" (1986, p.5-6). Every basin thus defines some specific **dynamics**, and inhibits any other.

To different kinds of **attractors** correspond different types of basins.

0244

BAYESIAN PROBABILITIES

→ **Probabilities (Bayesian)**

0245

BAYESIAN SYLLOGISM¹⁾⁽³⁾

The Bayesian syllogism has been introduced by V.V. NALIMOV and is based on Bayes probabilistic logic (1982, p. 284).

In NALIMOV's own terms: "It becomes possible to speak of the Bayesian syllogism. It may be regarded as a generalization of ARISTOTLE's syllogism (i.e. the categorical syllogism in which two initial categoric assertions linked by the common middle term yield the third judgement called the **inference**..., an assertion of absolute **value**, independent of any conditions).

"Whereas in the Aristotelian syllogism the inference is a logically clear assertion, in the Bayesian syllogism the inference is the redistribution of weights in the system of initial value **concepts**, determining the trend of thought on the logically structured **level**" (Ibid)

In a later work, NALIMOV adds: "In my interpretation, the Bayesian formula well known in statistics acquires a new **meaning**. From an auxiliary computational formula, broadly used in mathematical statistics, it turns into one setting the logic of propositions" (1985, p. 28)

→ **Bayes theorem; Bayesian probabilities; Parallel distributed processing**

0246

BAYES's Theorem²⁾

R. MATTHEWS (1997, p.38) explains Bayes's theorem as follows: "(The) theorem shows how to update your belief in a particular theory in the light of new **data**. Mathematically, it states:

Odds (Theory, given observed data) = LR x Odds (Theory)

where Odds (Theory, given observed data) are the odds on the correctness of the theory, given the new **data**, and Odds (Theory) are the so-called prior odds that the theory is correct - that is, a measure of the plausibility of the theory before the new **data** emerged. Precisely how that new **data** changes your beliefs is captured by the so-called "**Likelihood Ratio**" (LR), which is made up of two factors:

LR = Prob (getting the data, given theory is correct)

Prob (getting the data, given theory is wrong)"

BAYES's Theorem helps dealing with statements "that lie somewhere between absolute truth and falsity" (R. MATTHEWS, 2000, p.45). This is crucial for the **evaluation** of the soundness of any scientific result (and any belief in general), because, as **observers**, we have no way to appreciate "absolute" truth or falsity.

MATTHEWS explains: "... as you accumulate more **information**, BAYES's theorem shows that your original thoughts - flaky or well founded, right or wrong - become progressively less important... The scientific process contains

an ineluctable amount of **subjectivity** at the onset, but... it gives way to **objectivity** as the **information** accumulates. In other words, scientific **objectivity** is "emergent" (p.45).

It would be possibly better to say that it is "asymptotically emergent", because it is impossible to totally eliminate **subjectivity**. This **process** is closely related to POPPER'S **false-ability**. It is also obvious that asymptotic **objectivity** is better reached by recurrent debate and **consensus**.

→ **also: Epistemo-praxeological closure; Observability (Constraints on); Observation process; Probability (Bayesian)**

0247

BEHAVIOR^{1) - 4)}

1. "The system of interconnected and expedient **actions** carried out by an **organism**" (UNESCO-UNEP, 1983, p.6)

2. A repetitive sequence or **pattern** of **actions** or **operations**, and resulting **states**, characteristic of a specific system.

The second definition is more general than the first, since it can apply to non-living **systems**, as well as to societies of **organisms**.

The concept of behavior, when referring to a **complex system**, may be associated with an interconnected **network** of **actions**.

G. PASK gives the following examples: "The behavior of a steam engine is a recurrent **cycle** of steam injection and piston movements that remains invariant. The behavior of a cat is made of **performances** like eating and sleeping and, once again it is an **invariant** form selected from the multitude of things a cat might possibly do" (1961, p.18).

Models of numerous different behaviors can be constructed, but one **model** may be used to modelize analogous behavior of different systems, as for example cyclical **oscillations** in **homeostatic systems**, or **dissipative structuration** in **systems far from equilibrium**.

Behavior is thus a systemic-cybernetic concept of very ample significance and does not exclusively and necessarily have psychological overtones.

However, as stated by R. ESPEJO: "The greater the number of distinct behaviors that are recognized in a **situation**, the more complex it appears to be" (1988, p.140)

From a somewhat different **viewpoint** G. KLIR defines behavior as: "A particular **set** of **time-invariant relations** between certain quantities". He then proceeds to define three basic kinds of behavior:

Table: see entry **Behavior**

Type of system	Behavior of system	Outcome of behavior
State maintaining	Variable but determined (reactive)	Fixed
Goal-seeking	Variable and chosen (responsive)	Fixed
Multi-goal-seeking and purposive	Variable and chosen	Variable but determined
Purposeful	Variable and chosen	Variable and chosen

"1. **Permanent (real) behavior** - the **set** of all absolute **relations**;

"2. **Relatively permanent (known) behavior** - the **set** of all relative **relations** of a particular **activity**;

"3. **Temporary behavior** - the **set** of local **relations** within a distinct section of a particular **activity**". (1965, p.30)

He adds: "It should be remembered that permanent behavior is known only in some cases, e.g., when it is directly given in some engineering system" (Ibid)

Still from another perspective, A. ROSE-NBLUETH, N WIENER and J. BIGELOW (1943, p.22) proposed a **classification** of orders of behavior.

In turn, R.L. ACKOFF establishes the following behavioral **classification** of systems (1971):

see table below

0248

BEHAVIOR (Active)²⁾

"A system's **behavior** is determined not only by the **state** and influence of the **environment**, but also by the system's own **goals** presupposing the **transformation** of the **environment**, its subjection to the system's need" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.120).

According to these authors: "...in a system with active **behavior**, a crucial role is played by the **teleological** characteristics of the system itself and of its separate (i.e. distinct) **subsystems**, and by the **interaction** of these characteristics" (p.130).

Active behavior is possible only for a system endowed with **regulation** and **control mechanisms**, which must include a **knowledge** of its own **state** and that of its **environment**, including some **knowledge** of **past states**.

This concept makes sense particularly in connection with **autonomous** (= **autopoietic**) **systems**.

0249

BEHAVIOR (Adaptive)^{*}

→ **Adaptive behavior**

0250

BEHAVIOR (Anticipatory)^{1) - 2)}

The activity of a system that constructs a predictive **model** of itself, its **environment**, or both, in order to adapt itself to probable future **change**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

R. ROSEN found that such behavior is quite general in **living systems** of all kinds, even if at very different **levels** of systems **complexity**.

The notion of anticipatory behavior should be handled in a discerning way, in order to avoid logical contradictions: future **events** cannot of course exert influence on present ones, but what is *now correlatively* perceived or believed about what will probably or possibly happen, can. ROSEN gives the following example: "Many primitive **organisms** are negatively phototropic: they move toward darkness. Now, darkness in itself has no physiological **significance**; in itself it is biologically neutral. However darkness can be *correlated* to characteristics which are not physiologically neutral, e.g., with moisture or with the absence of sighted predators. The relation between darkness and such positive features composes a *model* through which the **organism** predicts that by moving toward darkness, it will gain an advantage" (1979, p.15).

This action of a *present prediction* upon the *present* behavior acts as a **regulation** or **control** and is called **forward activation**, the result of a **feedforward**.

ROSEN adds: "Of course this is not a conscious **decision** on the **organism's** part; the **organism** has no real option, because the **model** is, in effect "wired in" (p.544).

In animals with complex brains, however, particularly man, the **model** becomes much more complex and can evolve, becomes reflexive and self-corrective, and leads to changing **goal-directness**.

An obvious conclusion, stated by ROSEN (p.557), is the need for ever-perfected predictive **models**, in order to improve anticipatory behavior. This field should urgently be researched upon as to the anticipatory behavior of **social systems**.

→ **Club of Rome, Feedforward, System (Anticipatory) and Systems Dynamics**

0251

BEHAVIOR (Chaotic)²⁾

I. PRIGOGINE and I. STENGERS write: "A behavior is chaotic if **trajectories** outcoming from points as close as possible in the **phases space**, stray from each other in **time** in an *exponential way*". (1992, p.77)

This implies that, after a sufficiently long span of **time**, it becomes impossible to predict future behavior relying solely on the **initial conditions**. The authors explain that only a more accurate **knowledge** of these may better the **predictability** of behavior, but that such **knowledge** will rapidly become prohibitive in **costs** and in **time**.

While this is an abstract view, it corresponds to our practical **situation** in front of **complex systems** and it strongly limits our possibilities to govern them.

→ **Lyapounov exponent**

0252

BEHAVIOR (Coherent)¹⁾

The behavior of numerous **elements** or individuals which start to exhibit coordinated **interactions**.

This **phenomenon** can already be traced in physical effects (**BÉNARD's instability**) and chemical reactions (the **BELOUZOV-ZHABO-TINSKY reaction**). It heralds the **emergence** of higher **order structures** and, in living beings, of social **organization**.

0253

BEHAVIOR (Determinate)²⁾

G. KLIR thus characterizes determinate behavior (in **automata**): "The instantaneous **response** can be uniquely derived from the instantaneous **stimulus** and sometimes from past **stimuli** and **responses**; this is accordingly subdivided in:

1. **combinatorial** – the instantaneous **response** depends solely on the instantaneous **stimulus**;
2. **sequential** – there exists at least one **response** that depends not only on the instantaneous **stimulus** but also on the past **values** of some of the quantities" (1965, p.37).

KLIR opposes determinate behavior to **random** behavior

0254

BEHAVIOR (Eco-)^{1) - 4)}

The behavior of elementary units in a **network** as it becomes organized through their repeated **interactions**.

This **concept** has been promoted by J. ERCEAU and J. FERBER whose "... objective is to construct a society of **agents**... (true non-anthropomorphic micro-robots), capable of work within a hostile **environment**, and to improve their individual and collective **performances** through **mechanisms** akin to **learning**" (1991).

These authors include in their "society" reactive **agents**, communicating **agents**, rational ones and intentional ones. (See "**Multi-agents systems**").

In natural **ecosystems**, different types of behavior are distributed among different species or among various individuals of the same species. There appear to be a kind of spontaneous and distributed **control mechanism** peculiar to these systems.

Strikingly, eco-behavior could be used as a **model** for any type of **social systems**.

0255

BEHAVIOR (Eigen)

→ **Eigen**

0256

BEHAVIOR (Emerging)²⁾

Innovative behavior of a system or **network** that does not exist in any of its **elements** or **parts**.

Emerging behavior results from the combined **interactions** of some or many **elements**. Some of the **interactions** are simultaneous in different **parts** of the **network** or system, while others are sequential. This situation may lead either to what St. KAUFFMAN (1991) calls **anti-chaos**, i.e. **organization** at a higher level of **complexity**, or **deterministic chaos**.

In **multi-agent systems** global behavior emerges from the **interactions** of numerous "**agents**", whose abilities are more or less elementary and specific. This is a typical social **network situation**. It also seems to promise complex societies of simple **robots** in the future.

0257

BEHAVIOR (Functional)¹⁾

In order to be considered functional, any **behavior** must be **adaptive**, i.e. allow for a suitable **reaction** of the system to some **stimuli**.

However, functional behavior is more than a **functional reflex**, which is only a **response** to a **command**. A **functional reflex** may indeed endanger the system in some cases.

Functional behavior, even though its progress ceased at the reflex **levels**, involves the previous incorporation of a **variety** of possible reflexes into a **subsystem**:

1. which will be able to produce a considerable **choice** of distinct **sequences**, according to the general conditions (and not only to the specific **stimulus**)
2. which will be **integrated**, i.e. able to select the appropriate **response**.

0258

BEHAVIOR (Isopraxic)

→ **Isopraxic behavior**

0259

BEHAVIOR (Line of)²⁾

"A succession of **states** and **time-intervals** between them" (W.R. ASHBY, 1960, p.20).

ASHBY adds: "The first **state** in a line of behavior will be called the **initial state**. Two lines of behavior are equal if all the corresponding pairs of **states** are equal, and if all the corresponding pairs of **time-intervals** are equal" (p.243)

This is of course the basic condition for **homomorphisms** and **isomorphisms** between functional **models**.

0260

BEHAVIOR (Operative)¹⁾⁴⁾

The behavior of a **decision** maker or **operator** when trying to manage a system or correct some **disturbance** in a **function** of the same.

The following types of operative behavior have been identified:

- **skill-based behavior**: it is similar to an automatic behavior, practically without mental **activity**. The **operator** only reproduces behavioral **models** acquired by intensive **training**. Any alarm functions as a **trigger** for a kind of **conditioned reflex**
- **rule based behavior**: this behavior supposes a conscious mental **activity** and is characterized by the sequential **performance** of coordinated **tasks**, according to learned or written well assimilated **rules**
- **knowledge-based behavior**: the **operator**, in a more complex and not very common **situation**, must understand the problem, plan adequate **responses** and execute the corresponding **decisions**. This behavior generally includes reasoned **choices** made in due time on the base of a proper **understanding** of systemic **complexity**. A high level of personal **responsability** can be achieved in this way.

A frequent and very dangerous error is to give **responsibilities** of this last level to people trained only for **rule- or skill- based behavior**.

Human behavior in operative **situations** and in relation to mental **activity** seems to respond to the three following basic types:

- **Skill-based behavior**: a practically automated behavior generally produced by a long **training**. Such behavior allows a very quick and efficient operative **response**, but then only in situations similar to those met during the **training process**. The skill acquired by a pianist for example is rigorously related to the universal standard board of pianos
- **rule-based behavior**: a less automated behavior, in which a measure of mental **activity** is needed in order to select the correct behavior in different specific cases. Such behavior is not over-complex when the number of possible different cases is limited and corresponds to more or less similar or well known **situations**
- **Knowledge-based behavior**: an intelligent mental behavior needed to tackle quite complex and/or unusual **situations** wherein automated skills or **rule** application are wanting. In such cases an **operator** must be able to discover adequate procedures in **decision making** or in **design processes**.

→ **Christmas tree effect; Complexity; Decision tree**

0261

BEHAVIOR (Purposive)^{1) - 4)}

A. RAPOPORT observes that: "...mathematical analysis shows that the apparently purposeful behavior of the system is a consequence strictly deduced from the fact that it is **open**, not **closed**" (1966, p.8).

In effect, the need to process *specific inputs* of **energy**, **matter** or **information** in accordance with the internal nature of the system implies a behavior oriented toward the maintenance of defined internal **parameters**. This does not necessarily impose **consciousness**, and even less so, **teleology**.

We would probably have to distinguish between two types of purposive behaviors. The first one is, in animals, non-conscious *purposive* behavior (another semantic trap!) and the second is man's, based on **symbolic** capability (cf. L.von BERTALANFFY, 1967), that should be called *purposeful*.

Evolutionary **differentiation** seems to bear on a steadily growing capability to *create* new behavior within the **reference frame** of an already globally installed **understanding** of **environment** as well as **invironment**.

Such a capacity could be a result of the growing **variety** of effective and of potential neural **interconnections** in the **brain**, which provide the possibility of practically unlimited recombinations.

0262

BEHAVIOR (Random)²⁾

G. KLIR characterizes random behavior (in **automata**) as the one in which: "... the **response** depends statistically on the instantaneous **stimulus** and sometimes also on past **stimuli** and **responses**, accordingly subdivided into:

1. simple, where the instantaneous **response** depends (statistically) solely on the instantaneous **stimulus**;
2. complex - there exists at least one **response** that depends (statistically) not only on the instantaneous **stimulus**, but also on the past **values** of some of the quantities" (1965, p.37). Complex random behavior thus seems to be a characteristic of **ergodic** or **markovian systems** in general terms.

0263

BEHAVIOR (Reactive)¹⁾

A system's behavior "determined by **environmental input** in all essential points" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.130).

0264

BEHAVIOR SCHEDULE¹⁾

A. LOTKA introduces this interesting **concept** as follows: "We may say ... that the **organism** goes through a certain **routine** of motions or

activities which are rendered possible by its **structure**, and which, in turn, are a necessary condition for the continued existence of that **structure**. These **activities** in general involve the expenditure of certain quantities of free **energy**, and a part of the **energy** so expended, is spent necessarily in collecting (earning) a "replacement" amount equal to the total expenditure, to balance the account, to cover the *cost of living*" (1956, p.346).

By connecting behavior with **structure** (in a reciprocal way), this **concept** bridges a gap between those of **dynamic stability**, **organizational closure**, **hypercycle** and **behavior** in general.

It is possible to describe behavior schedules in a quantitative way, for example, as shown by LOTKA, by an estimation of the normal use of earned calories.

Behavior schedules can be modified, for instance by adaptive ethological **changes** in **habits**.

0265

BEHAVIOR (Self-organizing)¹⁾

E. JANTSCH distinguishes "the following three basic types of internal self-organizing behavior:

- *Mechanistic* systems do not change their internal **organization**;
- *Adaptive* (or **organismic**) systems adapt to **changes** in the **environment** through **changes** in their internal **structure** in accordance with **pre-programmed information** (e.g., engineered or genetic **templates**);
- *Inventive* (or human action) systems change their **structure** through internal generation of **information** (invention) in accordance with their intentions to change the **environment**" (1975, p.66).

This latter type corresponds to Singerian **adaptation**.

In JANTSCH's opinion, it could very well derail into unforeseen and dangerous developments (p.64-66). In effect, short term ill-conceived **changes** may become harmful later on.

0266

BEHAVIOR SPACE²⁾

"The collection of behaviors a system can follow, the **set of paths** a system is capable of taking" (K. KRIPPENDORFF, 1986, p.6)

This concept is interesting in that the observed behavior during a **time lapse** is not necessarily the only possible kind, but merely a special one, corresponding to certain internal and/or external **conditions**. What "always" happens is no sure-fire guarantee of the future of the system or of one of its **processes**.

0267

BEHAVIOR (Specific action)⁵⁾

A type of **action** standardised in accordance with a specific task.

A specific **action** pertaining to a **pattern** of behavior can be repeated without any adaptive **variations** as many times as needed.

Only **machines** – mainly so-called **robots** – can be programmed for specific action behavior.

Living systems, particularly human beings, are not efficient specific behavior actors, precisely because they are good at adaptive **variations**.

H. COLLINS observes: "We can replace workers on **production** lines with **machines**, but only after we have organised the factory so that the tasks can be accomplished through standardised behavior, rather than varying **actions**" (1992, p.39).

Specific action behavior thus introduced as **algorithms** and **routines**, become completely stabilized and **context** independent.

COLLINS adds: "The theory of the specific action behavior... gives us a simple test which highlights most of the difficulties of making **machines** that mimic human **action**" (p.39).

This is true at least for **machines** guided by **algorithms**, but could become less so for **machines** trained by **learning**.

0268

BEHAVIOR (State-determined)²⁾

"A behavior is state determined if an **observer**, knowing the **state** at t , is able to predict the **state** at $t+1$ with certainty" (G. PASK, 1961, p.28).

G. PASK rephrases the concept in a still more precise way: "A behavior is state determined if $X(t+1)$ depends in a *unique* fashion upon $X(t)$ and, in the **phase space**, this means that the **path** describing a state determined behavior *does not bifurcate*" (Ibid).

As stated by G. PASK, a state determined behavior "must either converge... to a fixed **state**, called the **equilibrium** point, or enter a behavioral **cycle**" (p.29).

The **equilibrium** point is also called a punctual **attractor** and the behavioral **cycle** is inscribed in a **confluent** or **basin of attraction**.

0269

BEHAVIOR SYSTEM²⁾

A **model** of a **data** system assuming that the **relationships** among **variables** are invariant.

This **model** is introduced by G. KLIR who says that these **invariances** are so "with respect to the supporting **medium** involved" (1993, p.32). The **invariances** can be in **time**, **space**, **space-time**, **population**, etc.... Furthermore: "The **relationship** may involve not only **variables** contained in the experimental **frame**, but also additional **variables** defined in terms of the former by specific **translation rules** in the supporting **medium**. When the supporting medium is **time**, for example, we obtain **lagged variables**" (Ibid).

And: "We say that a **data** system is represented by a behavior system if, under appropriate **initial** or **boundary conditions**, the support-invariant **relation** of the latter can be utilized for generating **data** of the former" (Ibid).

→ **Reconstructability analysis**

0270

BEHAVIORAL ALGORITHM^{2) - 5)}

A genetically inherited or learned behavioral **pattern** that became stabilized.

J. CORBARA and A. DROGOU give the example of the three basic **patterns** of behavior of some ants: taking care of the brood, seeking fodder or being inactive. The different **patterns** are in that case activated or deactivated through social **triggers** (1993, p.835).

Behavioral algorithms seem very basic for carrying out in an economical way many **routine** tasks. Training, a more channeled way of **learning**, leads in many cases to the acquisition of such algorithms (e.g. swimming, using a **language**, driving a car).

0271

BEHAVIORAL CHAINS

→ **Action Chain**

0272

BEHAVIORAL PROPERTIES¹⁾

J.W. SUTHERLAND states: "...behavioral properties of any real significance are generally dependent upon a **context** for their **viability**" (1973, p.37).

This should be understood in two different senses:

1. Behavioral properties are basically "constructed" by the system in accordance with its genetic characteristics (corresponding to its **archetype**, as well as its proper, more specific ones), which reflects the historical adaptive **evolution** of the **archetype**.

2. More specific behavioral properties are variations on the basic ones, learned in accordance with the special **situations** encountered by the system in its **environment**.

0273

BEHAVIORAL SPACE²⁾

"The **set** of **paths** a system is capable of taking" (K. KRIPPENDORFF, 1986, p.6)

According to this author: "A behavioral space represents, sometimes graphically, and/or abstractly,... just what a system can do, so that what it actually does can be seen as a special case determined by **initial conditions**, circumstances, **purposes**, etc" (Ibid).

Behavioral space is to **processes** what **states space** is to possible **states** of the system.

0274

BEHAVIORAL UNCERTAINTY⁵⁾

A certain **level** of leeway in behavior.

While behavior must be more or less narrowly channelled by mental and psychological **algorithms** in order to respond efficiently to a wide **range** of variations in the **environment**, a degree of leeway is also necessary for **adaptation**.

Behavioral uncertainty is especially developed in man and gives him an increased power to select alternative **responses** when faced with hitherto unknown or unforecasted **changes**.

It tends however to decrease with **ageing**.

Cognitive maps, which are necessarily normative, tend to reduce behavioral uncertainty, but at the same time allow for it, at least in some measure.

0275

BEHAVIORISM^{3) - 4)}

The school of psychology that considers that it is objectively possible to observe and describe animal and human **behavior**, stresses the role of **environmental constraints** upon such **behavior** in terms of **inputs** (**stimuli**) and **outputs** (**responses**), and admits that it is possible to modify **habits** by appropriate conditioning.

While it offers some systemic aspects, it is not really possible to admit behaviorism as a systemic theory because:

- with its over-emphasis on **habits** to explain **behavior**, it tends to trivialize the **relationship** of the acting animal onto its world *as it perceives it*.
- it reduces **relationships** between the animal and its **environment** to over-simplified **feedbacks** (a kind of simple and very **deterministic mechanicism**).
- it gives little consideration to the internal **organizational closure** of the animal, considering it only as apt to be conditioned and thus denying it any measure of **autonomy** (at least in B.F. SKINNER's version of behaviorism).

There is a strong antinomy between behaviorism and **constructivism** or **autopoiesis**.

0276

BEING, DOING, BECOMING^{1) - 3)}

According to J.L. LEMOIGNE, "An **object's** definition is made by triangulation: it includes

- a functional definition (what the **object** does)
- an **ontological** definition (what the **object** is)
- a genetic definition (what the **object** becomes)" (1977, p.39)

LEMOIGNE adds that this "Triadectics of being, doing and becoming is probably the key of **representation**, if not even of **knowledge**" (Ibid).

This important insight reminds us that none of the three definitions corresponds to an absolute **knowledge**:

- What the system actually does may be quite different of what we believe it does, or of our specific viewpoint in relation to our research;
- We do not know if the "real **object**" corresponds perfectly to the **model** we did construct (see "Ontological skepticism");
- It is not secure that our **forecasts** in connection with the future of the **object** are valid, nor even that it would be possible to make any valid **forecast**.

The trialectic concept of LEMOIGNE's is basic for the whole of his "Système General" Theory (p.40).

W. PANKOW writes on the same topic: "Being is becoming. Self-transcendent systems are **time** generating systems. Being and **time** are complementary aspects of **gestalt**. **Gestalt** has no origin: it is its own origin" (1976, p.21).

0277

BELIEF¹⁾⁴⁾

"Mental acceptance or conviction in the **truth** or actuality of something" (Am.Heritage dict., p. 121, 1978)

Beliefs are very significant in individuals and in social systems. It is debatable if "acceptance" is "mental". It seems generally to be rather emotional.

In any case, for an individual, beliefs are a pre-ordering factor of **reference frames**, whether rational, esthetic, philosophical or religious. But a rational belief may lead one to question a religious belief, or conversely. Different kinds of beliefs lead naturally to different **decision making and behavior**.

In any human group, as for example a business, or a political party, common beliefs are the indispensable common ground without which **cohesiveness** cannot be maintained and **coherent behavior** be sustained.

This remains true even if these beliefs are implicit and never overtly proclaimed.

Similarly, different **cultures** are different precisely because the basic beliefs shared by individuals in any specific culture are at variance with the beliefs of other ones.

In any culture, the **set** of beliefs acts as a general behavioral **control**, because it compatibilizes and coordinates individual behaviors (in German: Gleichschaltung)

Moreover, its beliefs set endows a culture with a kind of **immunity** to encroachments from other cultures. Unfortunately this derives frequently into intolerance and reciprocal hostility between individuals or groups alien to each other.

→ **Clanthink; Community; Communities (types of human); Compatibility; Group-think; Human Systems; Language and Culture; Semantics (General); Systems (Cultures as)**

0278

BELOUSOV – ZHABOTINSKII REACTION^{2)–5)}

"A complex chemical reaction involving the cerium-catalyzed bromination and oxidation of malonic acid by bromate ions" (J.S. TURNER, 1982, p.48).

A now famous chemical reaction, whose relation to **nonlinear systemic processes** studies is thus described by TURNER: "The great interest of the Belousov-Zhabotinskii (BZ) reaction lies in its unique ability to exhibit a wide variety of characteristic **nonlinear behavior**. Ranging from **homogeneous** chemical **oscillations** in stirred reactors to travelling chemical **waves** and stationary spatial **structures** in unstirred mixtures, the **phenomena** observed in this system include all the types of **nonequilibrium** coherent **structures** that have been studied theoretically in the past decades. In the last few years, besides, new experiments have suggested that the same chemical **processes** which give rise to coherent **phenomena** may also yield incoherent or **chaotic behavior** as well" (p.48).

The BZ reaction is an example of a **reaction-diffusion system**, resulting from the competition of a force that tends to produce **dissipative structures** and another that tends to dampen them out.

0279

BÉNARD's INSTABILITY^{2) – 5)}

A **phenomenon** of **structuration of forms** through **energy dissipation**.

This **phenomenon** was discovered by the French physicist BÉNARD at the beginning of the 20th century, but its **general systemic meaning** was not understood until PRIGOGINE's discoveries in **thermodynamics of far from equilibrium systems**.

F. DAVID PEAT describes this kind of instability as follows: "It occurs when a pan of water is heated on a stove or when hot air in the desert lifts tiny particles of sand into the air. If the pan of water is heated slowly, heat at first moves upward into the cooler water by conduction. Since no part of the liquid is far from thermal **equilibrium**, the surface is smooth and undisturbed. However, as the water at the bottom becomes hotter, and therefore less dense, it tries to rise while, at the same time, cooler water falls from the top. Under these competing **flows** the water is now **far from equilibrium** and it contains a mixture of **flows**, eddies and whorls... In fact, **chaos** has set in.

"As the rate of heating continues to rise, however, a **critical point** is reached at which the whole system moves from **disorder** to **order**. This occurs when heat can no longer be dispersed fast enough through **random** movements alone and the tiny eddies suddenly become magnified into large-scale **flows**. Almost

magically, movement in the liquid shifts from **chance** into a series of stable convection currents which have the effect of producing a regularly ordered **lattice of hexagonal** currents.

"... millions upon millions of molecules suddenly move coherently rather than in a **random** way – a **phenomenon** that recalls the convergent movements of **cells** in the slime mold (Note: see *Dictyostelium discoideum*) or electrons in plasma." (1988, p.78-9)

→ **Hexagonal space filling; Structure (Dissipative)**

0280

BENEFIT per unit cost²⁾⁵⁾

The relation between a system's **input** and the **resources** that it must spend in order to obtain them.

This relation must remain positive, i.e. it should yield a better than average return, at least as a general mean.

This is a very general relation, that can be observed from Biology and Animal Ecology to Business and Economics

In Economics for example, it is expressed through marginal utility.

It obviously governs **behavior** in any system in its relations with its **environment**.

When the **costs** of obtaining needed **inputs** cross a specific **threshold**, the system is losing its balance. If this **situation** is not corrected, the system could be on its way toward **collapse** of bankruptcy.

→ **Foraging theory; Stability (Dynamic)**

0281

BIFURCATION²⁾

The splitting of a **trajectory** into two or more new **trajectories**.

Bifurcations characterize states of **uncertainty**.

They occur in the "**region of the parameter space** where a **state** of a system becomes **unstable** and gives way to a pair of **states** in which a new **order parameter** has a finite **value**" (R. FIVAZ, 1991, p.31).

According to this comment by FIVAZ, a bifurcation is thus characterized by the **emergence** of a qualitative change in the nature of an **attractor**. According to I. PRIGOGINE and G. NICOLIS; "... (a) bifurcation is basically a "**decision making**" process. But because of the multiplicity of **choices** at the "decision" point, a **selection mechanism** is necessarily involved. Now all physical systems possess such a mechanism, in the form of **random fluctuations** that are generated spontaneously around the **deterministic evolution**" (1985, p.6)

Of course, "**decision making**" in physical systems does not imply any human willfully **meaning**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

PRIGOGINE also adds: "... the **phenomenon** of bifurcation is extremely general and ... there is a wide **variety** of solutions that can bifurcate: multiple **steady states**, **oscillating** solutions, propagating **waves**, etc. Also there could occur higher-order bifurcations" (1984, p.50).

It is by crossing a **critical value** in the **parameter space** that the **trajectory** becomes divided into two possible **trajectories**, corresponding to two different qualitative **behaviors**.

According to R.N. ADAMS "... a number of alternative further **paths**" is even possible (1988, p.66) and, at such "crossroads" any small **random effect** may lead to **nucleation** of new **structures**.

It thus becomes impossible to predict with perfect accuracy the future **behavior** of the system.

The **domain** of possible **behaviors** becomes discrete, and sudden **transitions** (i.e. "**catastrophes**") may occur from one **state** to another quite different one.

The first **bifurcation** signals the onset of **chaotic behavior**, proper of **non-conservative**, or **non-Hamiltonian systems**, also called **dissipative**.

The concept of bifurcation is a significant link between:

- the theory of **irreversible systems far from equilibrium** (i.e. **dissipative**)
- the mathematical theory of **catastrophes**
- the theory of **chaos**, or **topological dynamics**

According to S. WIGGINS such a **change** is a result of "qualitative **changes** that occur in the orbit **structure** of a dynamical system as the **parameters** on which the **dynamical system** depends are varied" (1988, p.62).

K.DE GREENE states: "A bifurcation is most generally the appearance of a new solution to reaction-diffusion equations at some **critical value**. Systems moving toward bifurcations reflect both **deterministic** and probabilistic features. These systems behave deterministically between bifurcation points; however, near bifurcation points, **fluctuations** are essential to **selection** of the **path** the system will follow. Such systems may be structurally **unstable** if arbitrary small **fluctuations** alter the mechanisms of **interaction** between system **elements**. Evolving **complex systems** show successive **instabilities** associated with successive bifurcations that produce increasing **coherence**" (1988, p.290).

0282

BIFURCATION AS AN IRREVERSIBLE PHENOMENON²⁾

I. PRIGOGINE and P.M. ALLEN write: "When bifurcation occurs, then **stability** of the existing **state** of the system breaks down, allowing the **amplification** of some small **random fluctuation** to occur and to carry the system off to one of the possible, new branches of solution".

And "... **nonlinear interactions** can give rise to bifurcating solutions of the phenomenological equations, such as those of chemical kinetics, for example, and this gives rise to new dynamic, coherent **structures**, which have been called **dissipative *structures**. However, even in **equilibrium systems**, bifurcating solutions can occur, but in such cases they correspond to the occurrence of an **equilibrium phase transition**" (1982, p.7).

According to F. HEYLIGHEN when a bifurcation takes place, pushing the system into one of several new **regimes**: "...the **process** is no longer predictable. We do not know which of the available **trajectories** the system will choose at the bifurcation point. The **process** becomes **stochastic**". (1989, p.366).

At a point of bifurcation the **process** becomes **divergent**. Thus bifurcations are antinomic to **equifinality**.

0283

BIFURCATION (Symmetry-breaking)²⁾

A bifurcation leading to the non-symmetric splitting of a rotating fluid as it solidifies.

The subject was introduced by H. POINCARÉ (1892, 1901) in relation to the study of rotating gravitating fluid masses in celestial mechanics. It seems that these were the very first examples of an incipient **chaotic behavior**

0284

BIFURCATIONS (Social)⁴⁾

E. LASZLO has proposed the following applications of the bifurcations **model** to societies. He makes a distinction among:

- **T bifurcations** "due to the destabilizing **effects** of technological innovations";
- **C bifurcations** "due to **instabilities** introduced by **conflicts** and conquests";
- **E bifurcations** "triggered by the internal **collapse** of the dominant institutions owing to mushrooming economic and social crises" (1987, p. 150).

LASZLO gives interesting examples of all of these bifurcation types, showing that the **model** is much more than a **metaphor**, or even an **analogy**, in social sciences.

0285

BIJECTIVE RELATION²⁾

A relation between two **sets** of **elements** such as any **element** of the first one corresponds to one and only one **element** of the second one.

Bijective relations are important in order to establish and verify a satisfactory relation between a **concrete system** and its **model**, or between general **models** derived from various **concrete systems**.

0286

BINARY CODE⁵⁾

A **code** which is used to express numbers on base 2, using 0's and 1's only.

Such a **code** permits the reduction of complex sequences of **decisions** to a succession of "yes/no" ones. It is based on **Boolean** logics and is perfectly fit for use in **digital computers**. It can be used in any type of **operations** corresponding to the third excluded logic.

0287

BINARY LOGIC

→ **LOGIC** (Binary)

0288

BINARY RELATIONS²⁾

Binary relations appear in **graphs** and **matrices**.

There are different types of binary relations, as follows:

- **reflexive**, by which a **node** is connected to itself through a **loop**
 - **symmetric**, by which two **nodes** are connected by two opposite **arcs** of the same value
 - **transitive**, by which a third or nth **node** is connected to the previous ones by an unbroken **path**
 - **antisymmetric**, where two **nodes** are connected by opposite **arcs** of unequal value
 - **equivalent**, if the connection is simultaneously reflexive, symmetric and transitive
 - **similar**, if the connection is simultaneously reflexive and symmetric
 - **ordered**, if the connection is simultaneously reflexive and transitive
- (After A. KAUFMANN, 1970, p.21-26).

This classification is helpful in order to distinguish more clearly different types of relations. The binary character of these relations is very convenient for computer **modeling**

0289

BINARY SIGNAL

→ **SIGNAL** (Binary)

0290

BIO-AMPLIFICATION^{1) - 5)}

The progressive concentration of chemical products through the pyramid of **living systems**.

A good example is the primary absorption of DDT or other toxic chemicals by the phytoplankton and their further concentration through the oceanic trophic sequence: small fishes, big fishes or penguins and other marine birds, and finally carnivorous marine mammals.

The possible effects for animal life in general are still ill known.

0291

BIOCENOSE⁵⁾

The living **community** of plants and animals in a **biotope**

0292

BIOCHEMICAL EVOLUTION⁵⁾

This subject was tackled by the belgian biochemist M. FLORKIN (1944)

While this technical work seems rather specialized, it has been important in showing the "unity in diversity" in the general **organization** of life in animals.

Florkin also considered, in his former "Introduction a la Biochimie Générale", biochemistry's relations with **biosphere** and the consequent **interrelations** of living beings to the biospherical **cycles**.

This research is probably still more significant today, after the deep alterations of the biosphere by man's activities.

0293

BIOCOMPUTATION⁵⁾

von FOERSTER biocomputation, in the words of W.R. WINBURN "... reveals how the **structure** of the nervous system and the **recursive** nature of **neural events** determine an **organizationally closed process** of **cognitive development**...

von FOERSTER explains how **autopoiesis** and **cognition** may operate in accordance with the mathematics of **recursive function** theory, in which an infinite series of **recursive operations** in a closed algebraic system develops stable **values** that produce themselves (i.e., **eigen values**, the German term for self-values) (1991, p.565).

0294

BIOCYBERNETICS: Its eight basic rules^{2) - 5)}

F. VESTER thus defines and comments the basic **rules** of biocybernetics:

"1. **Negative feedbacks** must predominate over positive ones.

... **Positive feedbacks** provoke **reinforcements**. Negative ones protect **stability** against **perturbations** and avoid **thresholds** overcrossings.

"2. Systems **functions** must be independent from **growth**.

... Energetic and material **flows** become constant in the long run. This limits the influence of **irreversibility** and uncontrolled crossings of **values limits**.

"3. The system should be **function** oriented, not product oriented.

... Resulting **variability** enhances **flexibility** and **accommodation**. The system becomes able to survive variable requirements.

"4. Use of available forces, according to the Jiu-Jitsu principle instead of boxing method.

... Outside **energy** is better used (**energy** cascades and chains), while internal **energy** is mainly used for steering. This enhances **self-regulation**.

"5. Multiple use of **functions**, organizational **structures** and products.

... This reduces **flows**, increases **integration** and reduces **energy**, **matter** and **information** expenditures.

"6. **Recycling**. Re-use through cyclical **processes** of **waste** and residual heat.

... Amalgamates **outputs**. When **flows** become **cyclically** organized, **irreversibilities** and **dependences** are restricted.

"7. **Symbiosis**. Reciprocal use through exchange and harmonious **coupling**.

... Favours limited runoffs and shorter transport lines. Diminishes **flows** and external **dependence**, while increasing internal **dependence**. Limits **energy** use.

"8. Biological **design** of products, **processes** and organizational **structures** through **feedbacks** planning with the **environment**.

... Takes **endogenous** and **exogenous rhythms** into account, as well as useful functional matches. Harmonizes the **system's dynamics**. Allows for the **integration** of new **elements**, in accordance with the eight basic **rules**" (Adapted from F. VESTER - 1983, p.82).

These basic **rules** could seemingly be extended to **groups** and social systems, as a groundwork for **sociocybernetics**.

0295

BIOLOGICS^{2) - 5)}

"A field of research intended... to establish super-additive **nonlinear** composition **rules** for the **elements** of **living systems**" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.160).

This field was introduced by H.von FOERSTER (1958, p.240-255), who spoke of "biological computers" and established the differences between the ways of internal **organization** of electronic computers and **living systems**.

In these, "...as the general case, the **function** "phi" of the **whole** exceeds the sum of the **functions** of the **parts**:

$$\Phi(x,y) > \Phi(x) + \Phi(y)$$

(BLAUBERG et al, p.160).

The subsequent development of biologics led to the concepts of **autopoiesis**, **self-reference**, **eigen-values** and **organizational closure**, and to a better **understanding** of **neural networks**.

More recently, it seems to open the way toward a still more general **understanding** of social **nets** and kinds of "social robotics" and highly **parallel** computing (**connection machines**).

0296

BIOLOGY (Relational)¹⁾⁵⁾

Organismic biology, as developed by Bertalanffy, Needham, Weiss, Woodger and others was one of the roots of systems theory, as a more general **transdisciplinary worldview**.

It was however not the only one. D. Gernert writes: "In the late 1920's. a pioneer of mathematical biology, Nicholas Rashevsky, set up mathematical **models** of specific biological **processes**, such as nerve excitation, cytokinesis, cardiovascular dynamics, central nervous **functions**, and many others. This was done with **mathematics** of that time...

"Later on, however, Rashevsky himself was more and more worried by doubts about the reach of his **models**, and looked for "a successful mathematical theory which would treat the integrated activities of the **organism** as a **whole**" (Rosen, 1994, p. 421). His endeavours led to what he called relational biology, as distinct from quantitative or metric biology. What really counts is no longer one or another **variable**, accessible to physical measurement, like blood pressure or electric potential at a certain spot, but the overall **structure**, which can be expressed, e.g., by a set of **organs** and the set of the relations between the **organs** (see e.g. Rashevsky, 1967) (quoted from D. Gernert, 2000, p. 157-58) Gernert adds: "Molecular biology, developmental biology and other fields require fundamental **patterns**-related **operations**: **pattern generation**, **pattern transfer**, **pattern recognition**, **pattern interpretation** and **patterns application** (Ibid.)

The same aspects became also apparent in **ecology** and in animal **ethology** and **zoo-semiotics**, as for example in the **interpretation** of biological molecules (pheromones, etc) as **signs** carrying **meanings** between animals, and even between plants and animals.

0297

BIOMATRIX⁵⁾

The global **network** of living beings (After G.G. JAROS, 1994, p.5-6)

The biomatrix is a **hierarchy** of many **levels**, all interconnected. JAROS considers the isolated study of any **part** (in his vocabulary: "**tel-eons**") of the **network** as quite difficult, in view that his theory corresponds mainly to the study of **processes**.

0298

BIOMORPHS²⁾

Graphical **structures** that represent, in a very simplified way, **processes** of **evolutionary transformations**.

R. DAWKINS (1986) introduced these curious **models** that, through **processes** of splitting and growing according to some **rules** prescribing the **behavior** of different "genes", can proceed from very simple to quite complex **forms**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0299

BIONICS⁵⁾

The science of **artifacts** or artificial systems whose **structure** and/or **operation** is imitated from natural systems.

It also includes the study of the natural **design of living systems** or their **parts**.

Bionics started with the **design** of architectural **structures** and, later on, of artificial limbs, for example. It is now progressing apace through the study of natural **processes** of **organization** and **regulation**. A. GIORDAN proposes the name of **physionics** for this extension of bionics (1996, p.81-6).

0300

BIOS¹⁾⁵⁾

A natural **process** mainly in **living systems** that continually creates novel and transient **patterns** (H. Sabelli, pers. comm.)

Sabelli develops the concept as follows:

"As unpredictability defines **chaos**, novelty defines bios" "Biotic patterns have been identified in time series of:

- heartbeat intervals
- economic indexes
- series generated by the process equation that formulates **process theory**

"Bios resembles natural processes and human **language** in continually generating new patterns. In contrast, an **attractor**, including **chaotic** attractors, is changeless-the more it changes, the more it stays the same. Bios is also characterized by: 1) **asymmetric** rather than symmetric statistical **distribution**, 2) multiple **fixed points**, 3) high self-correlation (PEARSON's **correlation**), 4) anti-persistence (Hurst exponent <0.5), 5) patterned wavelet and **recurrence** plots resembling those obtained with 1/f **noise**, and 6) ring patterns in complement plots. In contrast to **random** series, bios is characterized by determined novelty and determined **recurrences** rather than abundant recurrence and low **determination**."

Around this basic concept, Sabelli and his collaborators have developed important applications in medicine and psychiatry, establishing a much closer connection between physiological and psychological disorders.

Sabelli is attached to the Rush Hospital in Chicago.

0301

BIOSEMIOTICS¹⁾³⁾⁵⁾

The study of the origins of **meanings** as a problem of biology (K. Kull, 2000, p. 91)

"A new **field** which concerns itself with **signs** in biological systems, ranging from **communication** among animals to the individual **cells'** genetic **code** as a **sign** system of its own" (Cl. EMMECHE, 1994, p.126)

The field is also known as **Semiotic Biology**

The beginnings of Biosemiotics can be traced back to J.von UEXKULL (1928, 1934)

However, the subject lay dormant for many years. It is now reviving, specially with G. WITZANY in Austria (2000), M. BARBIERI, University of Ferrara, Italy, K. KULL, University of Tartu, Estonia and the "Cybernetics and Human knowing group" of S. BRIER, in Denmark.

The following statement by WITZANY, quoted by Kull (2000, p. 92) seems to clearly define the central idea of Biosemiotics: "...living nature is structured and organized in a **language-like** and communicative manner, i.e. that all **organisms**, including humans, are members of a global **community of communication**... Evolutionary **history** could then be understood as a developmental history of **interaction** semi-oses"

→ **Biosphere; Colony; Ecosphere; Ecosystem; Ecosystems dynamics; Ecosystemic relation; Evolution(Co); Gaia hypothesis; Information transmission; Stigmergy; Swarm; World Engine**

0302

BIOSOMA⁴⁾⁵⁾

The indissoluble **combination** resulting from the **interactions** between **biology**, society and **machines** (G. BUGLIARELLO, 1998, p.230)

BUGLIARELLO, who introduces this interesting concept, comments: "**Technology**, the **process** that human societies devised to produce and use **machines**, is in itself the quintessential biosoma" and "Despite the prevalence of such bio-socio-**machine** complexes, we rarely consider their broad implications. Nevertheless, our future depends on understanding the different characteristics, potentials and **pathologies** of the three **elements** of a biosoma and the opportunities that a well-guided **synergism** can offer".

The author adds: "Problems arise in a biosoma when there are imbalances among its **elements**... The social **element** of a biosoma responds slowly to innovations in the **machine element**. These frequently require new organizational **patterns**, new laws, the development of new **perceptions** or the evolution of new customs"

Moreover: "The human **element** of a biosoma is bound to commit **random** errors in **performance**, and it is powerfully affected by psychological factors" (p. 229-31)

0303

BIOSPHERE¹⁾

The global **space** occupied on our planet by **living systems** within their total **environment**.

The term "Biosphere" was introduced by the Russian geochemist Vladimir VERNADSKY (1863-1945) in 1926 (see 1929)

In 1935, A.G. TANSLEY introduced the closely related concept of "Ecosystem"

The biosphere is merely a "... thin covering of the planet that contains and sustains life" (UNESCO-UNEP, 1983, p.6)

The existence of the biosphere is the result of the ability of living beings to construct and maintain complex **structures** by **dissipating** electromagnetic **energy**, at the high **cost** of major global **entropy production**. However, it seems that globally, through what LOTKA called the **world engine**, this **process** tends to respect PRIGOGINE's **theorem of minimum entropy production**... save the puzzling fact that, at present, mankind seems to be violating this principle on a massive scale.

According to J. LOVELOCK, the biosphere is an **integrated system** wherein **energy**, mineral **elements** - gaseous, liquid and solid - and living beings find themselves enmeshed in a global **symbiosis** in continuous **evolution** through **time**. This is the so-called **GAIA hypothesis** (1979).

A deeper **understanding** of the numerous **symbiotic** exchanges within the biosphere seems to be an urgent condition of **survival** for mankind.

Recently, E. ODUM proposed a **parasitic model** of the **relation** of mankind with the biosphere (1997).

Such a **model** seems indeed close to the actual and present ways of man's **relations** with our planet. Possibly our challenge is now to shift from a **parasitic relation** at least to a **commensalist** one and, hopefully to a **symbiotic** one. In fact, the idea is not new: It was proposed (in 1935!) under the guise of an "**Interdependence** declaration" (between plants and animals - among them, men of course) and an "Ecological Constitution", by W.P. TAYLOR, at the time President of the American Society of Ecology.

...So many significant ideas lost in the mists of the past!

0304

BIOTOPE⁵⁾

"A small geographic unit occupied by a **community** of plants and/or animals and characterized by a high degree of uniformity in its main climate, soil and biotic conditions" (UNESCO-UNEP, 1983, p.7).

A sand desert, or a small island, or a lake are examples of biotopes as defined by UNESCO-UNEP lexikon.

As a rule the plant-animal **community** entertains **symbiotic relations** and fluctuates in relation to the **environmental** conditions.

0305

BISOCIATION³⁾

The supposed interlocking of two **matrixes**, or **frames** of thought, leading to creative ideas.

This concept was proposed by A. KOESTLER, as the sudden **association** of "two self-consistent, but habitually unconnected **frames of reference**". KOESTLER explains: "I have coined the term "bisociation" in order to make a **distinction** between the routine skills of thinking on a single "plane", as it were, and the creative act, which... always operates on more than one plane" (1964, p.35).

Bisociation is generally sudden and unexpected. Numerous examples are known in sciences and the arts.

Bisociation, as a **model**, is in fact an attempt to explain the way **analogies** (or even significant **metaphors**) suddenly crop up.

The concept seems also related to K. STEINBUCH's **learning matrixes**.

0306

BIT (= Binary digit)⁵⁾

"The unit of selective **information-content**... which determines a single **choice** between equiprobable alternatives" (D. MCKAY, 1969, p.172).

This unit of quantity of **information** is also sometimes called the HARTLEY, as this author studied **transmission of information** as early as 1928.

A bit represents a single yes/no **decision** and is the basic unit in **digital computers**.

The bit capacity of a **channel** is the number of bits transmissible per second (p.175).

0307

BLACK BOARD⁵⁾

A zone of common access in a **distributed artificial intelligence network** where **information** can be traded between autonomous **modules**.

E. BUCHBERGER describes it as the: "Global **data structure** which stores all the intermediate and final results in an **expert system**" He adds: "The blackboard is mostly **hierarchically** organized. Any **data** exchange between **programs** (or **knowledge** sources) ensues on the blackboard" (1987, p.29).

Another possible **communication** mode is by reciprocal sending of **messages** between the **modules**. In this case **criteria** of **channel availability** and **periodicity** must be established.

This, interestingly, seems a good **model** of the exchange of **information** in **human systems**: an example could be the electronic trade boards in stock markets, which **information**, furthermore, can be transmitted over electronic **networks**.

0308

BLACK BOX²⁾

"A box to which **inputs** are observed to lead and from which **outputs** are observed to emerge" (St. BEER, 1968, p.293).

The "black box" **model** has been - according to ASHBY - introduced by J.C. MAXWELL to "justify the building of functioning **descriptions** (in his case equations) that accounted for the observed **behavior** of some **phenomenon** when the workings of the **phenomenon** were not clearly visible" (R. GLANVILLE, 1982, p.1)

And "Briefly, a black box can be characterized as:

- a) being believed to be distinct
- b) having observable (and relatable) **inputs** and **outputs**
- c) being black (that is, opaque to the **observer**") (Ibid., p.1)

Of course, any black box is black for some specific observer, i.e. becomes a **construct** of the observer through his peculiar way of **observation**.

GLANVILLE, who discusses widely the black box model, adds that, after experimenting with the box, "what the observer has is a functional **description** that has worked in the past. That it will continue to do so is a pure article of faith: The black box regularity is an **assumption**" (Ibid, p.2).

However, when repeated **observations** produce similar results, this assumption is reinforced and "it is said that the black box has become white. The whiteness (as WIENER, 1948, asserts) is not a property of the box, but of the observer's **interaction** with it" (Ibid, p.4).

Viewed possibly from outside (by another observer), the interaction between the black box and the observer is, in fact, between two black boxes, and the whole system is thus a higher level black box.

In order to reach some **consensus** about a (tentative) conclusion we should thus clearly state our own observation **level**.

The black box can be either a concrete experimental **artifact**, or a conceptual **model**.

R. ESPEJO writes: "The black-box **construct** is a shorthand for the real world, that is, for the **transformations** actually taking place in it" (1988, p.140).

It however should never be forgotten that different **observers** may interpret the same black-box **behavior** in different ways (W. KARGL, 1991, p.577). The internal **organization** of this box is at the start of the experiment totally unknown. It must be conjectured by making hypotheses about the links between **inputs** and **outputs** and modifying these hypotheses as the experience is furthered.

St. BEER comments: "The reason why we contemplate a box having such odd properties, is that the more familiar box in which something is known about the internal **connectivity**, has its **variety** (already) **constrained**... Even if an arrangement having fairly high **variety** were chosen, the potential **variety** of all the other arrangements which could have been built in is

suppressed. But a black box is assumed to be able to take on any internal arrangement of **input-output connectivity** at all; it can therefore proliferate maximal **variety**" (Ibid.).

→ **Grey box**.

0309

BLACK BOX METHOD^{2) - 3)}

"A **strategy** for investigating a complex object without **knowledge** or assumptions about its internal make-up, **structure** or **parts**" (K. KRIPPENDORFF, 1986, p.7)

The general idea of this **method** is to send **inputs** into the system and to monitor the resulting **outputs**, making conjectures about the internal **processes** within the system that can explain how a specified **input** produces a specific **output**. In general, systems are "grey" boxes, i.e. **entities** about which at least something is known.

The black box method is widely applied in engineering, biology and other sciences, because of its **heuristic** value.

However, as stated by KRIPPENDORFF: "The **isomorphism** between the black box and its **model**, which the **method** aims to establish, does not imply **structural** correspondences between the two" (Ibid). One should thus be careful and not extract unwarranted conclusions from experiments that could be incomplete or ill interpreted.

0310

BLACK BOX OR BLACK ENGINE ?³⁾

J.L. LEMOIGNE proposed to dynamize the **black box model** (1977, p.99).

From the systemic viewpoint the **black box** does not merely possess one determined **state**. On the contrary it develops a series of successive **states**, as it possess a **diachronic structure**. Only by registering large series of **behaviors**, resulting from a great **variety** of **stimuli**, corresponding to very varied global **situations**, could we discover part or the **whole** of its internal **organization**.

This is why LEMOIGNE puts forth the concept of "black engine", which is of course implied in the **understanding** of the **black box model** by most cyberneticians and systemists.

0311

BLINDSPOTS³⁾

The non-**perception** of some aspects of **problem situations**.

H.von FOERSTER uses the example of the ocular blindspot as a **metaphor** for psychological and mental selective blindness. P. LEDINGTON has given a remarkable example of this anti-systemic disease (1992, p.57), but many others are well-known. The basic causes are the difficulties for specialists to **see** aspects of a **situa-**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

tion outside their own field, their feeling of righteousness about their own way to tackle a problem and their tendency to mere technical patching up.

LEDINGTON observes that there is also a kind of communities blindness – through **subsumption** of individual and **groups** blindness – which does not allow them to face their problems in a coherent way.

G.de ZEEUW's "invisibility" and R.S. ACKOFF's fables and parables are closely related to the blindspots problem.

The elimination – or at least, **reduction**- of blindspots can be obtained through **conversation** among various **observers** who observe the same **situation**. In effect, each one observes or can observe the blindspots of the other observers and thus contribute to their detection

0312

BLOCKING MECHANISM¹⁾

In relation to the existence of **functional cycles**, J.von UEXKÜLL, as early as 1928, showed the presence in systems of mechanisms able to block functional **processes** when they could cross a **threshold of instability**.

He added that the blockage is absolute in the case of a critical **threshold** whose crossing would provoke the systems destruction. However, when the **process** leads to **fluctuations** within acceptable **limits**, the mechanism merely acts as a guideline (1979, p.164).

von UEXKÜLL's concept may be generalized, considering that any **function** in a **complex system** appears to be controlled by a **pyramid** of hierarchical blocking **mechanisms** at different **levels**.

→ **Slaving Principle**

0313

BOIDS²⁾⁵⁾

Computer **models** of birds used to study **flocking behavior** in real birds.

These "computer birds", designed by C.W. REYNOLDS, are assigned the following individual **rules of behavior**:

"1. Maintain a minimum distance to other **objects** (including other boids) in the **environment**.

"2. Seek to adjust speed according to the other boids in the immediate **vicinity**.

"3. Maintain the position in the **vicinity** of that **location** considered by the boid to be the center of the flock (the "center of gravity" of the other boids nearby)

"A migratory urge is built into the **model** and specified in terms of a global direction, ...to make sure that the flock does not remain in the **location** but continues forward"

These **rules** are sufficient to elicit collective **behavior** of the boids, as for instance avoid by suitable dispersal, obstacles introduced in the modeling **space** and thereafter reconstruct an ordered **flocking**. (C. EMMECHE, 1994, "Schools, Shoals, Swarms", p.89-90)

0314

BONDING MECHANISM (Inchoate)²⁾

The incipient or not yet perfected establishment of bonds between **elements**.

This concept is discussed by J. BRYANT (1991), p. 113-120) in relation with the progressively organizing **linkages** among **neurons** in the **brain**. He writes, about synaptic **links** between neurons: "We shall assume that (such) transient electrochemical states actually do occur when neurons fire; and we shall call them inchoate bonds, since they function in a matter similar to, and as prior conditions for the **growth** of a synaptic bond"(p.114)

Analogous **mechanisms** are probably active in any system developing the internal relational **organization** among its **elements**. It should be useful to discover their existence and characteristics in all **complex systems** in their formative **process**

The study of **globalization** processes in these terms could be useful

→ **Autogenetic system precursors; Engram; Memory;Parallel distributed Processing; Zero system**

0315

BOOLEAN ALGEBRA²⁾

The algebra corresponding to discrete (or finite) mathematics.

This algebra was introduced by the British mathematician and logician G. BOOLE in his book "An Investigation in the Laws of Thought" (1854)

J. WARFIELD resumes: "There are precisely two **constants** in Boolean algebra. They are 0 and 1. A Boolean **variable** *x* is an unknown that may take only the values of the constants, that is 0 or 1.

"The complement of 0 is 1, and the complement of 1 is 0. The complement of a Boolean **variable** *x* is written $\bar{x}$. It is also called the "negation of *x*" or may be read simply as "not *x*" (1989, p.208).

The parts of Boolean algebra which are relevant for systemics are "... **sets** and partitions, **orders** and partial orders, **binary relations** and **lattices**..., vectors, **matrices** and **digraphs**" (Ibid)

WARFIELD develops these aspects and gives references (p.208-84). He developed his theory in notably systemic terms.

0316

BOOLEAN formulation of a network²⁾

Let us suppose *N* Boolean **automata** (able to transmit only the values 0 or 1) that are connected in a network. At any moment *t*, each automaton has a value 0 or 1, which is function of the value of a number of other automata in the network at the instant *t-1*. In such a network there are 2^N possible **configurations** (i.e. 10^{30} for a network of 10 automata with all their potential connections) (adapted from H. ZWIRN, 2002, p. 54)

As it is not possible to consider simultaneously the behavior of many automata (as it depends from the others and that **communication** is neither **isochronic**, nor isospatial, the behavior of the network is difficult (practically impossible) to forecast. However"...as the number of possible configurations is limited, the network's global behavior must be cyclical... However, the **cycle** is necessarily very long and the network's dynamics will seem chaotic" (Ibid)

0317

BOOLEAN FUNCTION²⁾

"A logical switching **rule** which specifies the **activity** of a **variable** in response to all the possible combinations of **activities** in the **input variables**" (St. KAUFFMAN, 1993, p.65).

St. KAUFFMAN writes: "The Boolean function specifies for each possible combination of current **activities** of the **input variables**, the **activity** of the regulated **variable** at the next moment. For example, an **element** with two **inputs** might be active at the next moment if either one or the other or both **inputs** are active at the current moment" (1993, p.188).

There are two Boolean functions:

- The **OR function**, "which says that a **variable** will be active if any of its **inputs variables** is active" (Ibid).
- The **AND function**, which "declares that a **variable** will become active only if all its **inputs** are currently active" (Ibid.).

These very simple **rules** were enounced originally by George BOOLE and are of cardinal importance for any study of **networks**.

0318

BOOLEAN NETWORK²⁾

"A system of **binary variables**, each with two possible **states of activity** (on and off), coupled to one another such that the **activity** of each **element** is governed by the prior activity of some **elements** according to a **Boolean switching function**" (St. KAUFFMAN, 1993, p.182).

St. KAUFFMAN writes: "In a Boolean network, each **variable** is regulated by others that serve as **inputs**. The dynamic **behavior** of each **variable** – that is, whether it will be on or off at the next moment – is governed by a logical

switching **rule** called a **Boolean function**" (see above) "The **function** specifies the **activity** of a **variable** in response to all possible combinations of **activities** in the **input variables**... One can calculate how many **Boolean functions** could conceivably apply to any **binary element** in a **network**. If a **binary element** has K **inputs**, then there are 2^K possible combinations of **inputs** it could receive. For each combination, either an active or inactive result must be specified. Therefore, there are 2 to the 2^K power possible **Boolean switching rules** for that **element**" (1991, p.67)

Many, if not all social **interrelations** in the most general sense seem to be amenable to **network modelling** in the Boolean sense as for example: neural **nets** in the **brain**, **nets** in **connection machines**, social interactions in **groups** and, possibly in the future **networks of robots** (see for example R. BROOKS, 1991)

0319

BOOLEAN NK NETWORK (Autonomous random)²⁾

A Boolean network whose **inputs** are all of **endogenous** origin.

Such networks are used by St. KAUFFMAN for the study of biological systems (1991), but have obviously a potentially wider field of applications, as for example in **languages** and in natural or artificial social systems.

The concept also seems to be related to **autopoiesis**, **organizational closure** and **autocatalytic hypercycles**. In KAUFFMAN's words: "A critical feature of random Boolean networks is that they have a finite number of **states**. A system must therefore eventually reenter a **state** that it has previously encountered... It will consequently **cycle** repeatedly through the same **states**" (p.66)

For a full development of the NK model, see reference.

0320

BOTTOM UP¹⁾

The progressive **self organizing mode** of a system or **model** composed of numerous **elements** each of which endowed with limited elementary capabilities and able to interact in a not absolutely determined way.

This notion has been described as follows by J. ERCEAU and J. FERBER in their study on **Distributed Artificial Intelligence**:

"**Agents** endowed with an elementary **behavior** potential, of the type **stimulus-action** (for example: to be attracted by a **signal**) are able to interact. From these local **interactions**, **structures** arise, which appear as globally organized. "Intelligence" thus emerges from the **interactions** of a great number of **agents**, individually devoid of "intelligence". An **analogy** sometimes used here is the anthill, the termite-hill or the beehive" (1991, p.755)

Furthermore: "The elementary units have thus specific **behaviors**, which do not necessarily coincide with **subfunctions** of the wanted global **function**. This will emerge from the **interactions** among elementary units.

"...In the bottom-up approach, the system organizes itself to react in an adequate fashion in every case, from which its **flexibility** results. Furthermore, a breakdown in some unit does not impair the global working of the **whole**, thus conferring its robustness to the system" (Ibid).

This **description** seems to fit even very complex **social systems** (i.e. systems including a very great number of **elements** capable of undergoing a very considerable number of **interactions**). As well as to societies of insects, it can probably be extended to societies of **automata**, to human societies and, possibly to societies of neurons in the **brain**.

As to **models**, for instance in **systems dynamics**, the bottom up procedure insists on starting with complete **models** of all the separate subsectors. D. MEADOWS et al state that these "should be carefully estimated, tested, elaborated and explored, so that one understands and has confidence in each part of the **model** before they are fitted together" (1982, p.274)

Still, in the case of the **Systems Dynamics model**, the **process** of fitting together, far from spontaneous, is decided by the modelizer and thus more or less depends on her/his subjective views.

The "bottom up" approach should not be exclusive of the "**top-down**" one. Both are in fact complementary, as expressed by Cl. PAHL-WOSTL (1993): "...the **dichotomy** between **top-down** and bottom-up **control** converges to a mutual and inseparable **dependence** on both factors. Neither a purely **reductionist** approach nor a merely **holistic** perspective is sufficient to encompass the intrinsic nature of the systems **behavior**"

0321

BOUNDARIES of a PROBLEM^{1) - 3)}

According to St. BEER, determining the boundaries of a problem "is the most difficult problem in **operational research**". He adds: "In practice the scientist needs to enlarge the scope of his study in every dimension until the factors he is bringing in seem to make no tangible difference to the answers he is getting" (1968, p.53)

BEER's comment could very well be extended to the whole research on **complex systems**.

Furthermore, we should never forget that the accuracy of the definitions of boundaries depends on the perceptive competence of the **observer**: what is tangible? to whom?

See "cognitive **blindspot**", "**invisibility**", "**underconceptualization**"

0322

BOUNDARY^{1) - 3)}

"The **subsystem** at the perimeter of a system that holds together the **components** which make up the system, protects them from **environmental stresses**, and excludes or permits admission to various sorts of **matter-energy** and **information**"

This is J. MILLER's definition in his list of the **20 critical subsystems** of any system (1978, p.3)

In B. BANATHY's words: "The boundaries of a system delimit the system **space** and set aside from the **environment** all those entities that make up the system" (1973, p.85)

K. BAUSCH describes boundaries as the "**parametric** conditions that delimits and define a system and set it apart from its **environment**" (Glossary - Personal communication)

The concept of boundary is basically ambiguous, in two different ways.

First, the boundary separates the system from its **environment** by defining what is inside and what is outside the system. In some cases however, it is difficult to distinguish precisely if some **elements** of the boundary belong to the system or to its **environment**... or to both.

Besides, the boundary does not define an absolute enclosure. It allows some specific **inputs** and **outputs** and bars others. It is selectively permeable.

In L. CARLSON-SABELLI and H. SABELLI's words: "Boundaries, when they exist, are **interphases** where **opposites** coexist, neither sharply delimited as in logic, nor simply gradual **transitions**, but actual areas of interchange and/or **conflict**, as illustrated by cellular **membranes**, and by national boundaries. The **basins** relative to two **attractors**, for instance, can penetrate each other in a manner which is **topologically** very complicated, rendering the outcome undetermined" (1992, p.681).

Furthermore, the boundary may be open or closed, in relation to the circumstances which affect the system and its **environment**.

T.F.H. ALLEN and T.B. STARR (1982, p.262) define the boundary as "a **distinction** made by an **observer**" and add: "Artificial boundaries are drawn arbitrarily and haphazardly. Natural boundaries are still arbitrary, but tend to be robust under **transformation**. That is, natural boundaries coincide for many distinct **criteria**".

Quoting G.H. GOODE and R.E. MACALL, G. P. SHCHEDROVITZKY writes "... boundaries pass over broad vague territories and the search for their precise position would elicit large but fruitless controversies" (1966, p.35)

These difficulties move G. WEINBERG to write: "**Interface**" is a more useful word than "boundary", for it reminds us to pay attention to the **connection** and not just the separation between system and **environment**" (1975, p.147)

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

Boundaries of physical systems are at the atomic or molecular **level**. In **living systems** they become organized as permeable **membranes**. In an **organization** they can be material enclosures as well as the **behavioral** result of abstract **criteria** of membership.

0323

BOUNDARY CONDITIONS^{2) - 4)}

"...a **set** of supplementary **constraints** that the solutions of differential equations must satisfy at all times" (T.F. ALLEN and T.B. STARR, 1982, p.262).

It appears from the context that these authors understand that each **set** of boundary conditions corresponds to a typical **hierarchical level** (p.44).

As stated by H. HAKEN, boundary conditions can be **periodic** (1983, p.269). Consequently, there are specific boundary **variables** which affect boundary conditions.

J. PLATT writes: "The surface may be taken as passing through a family of points where some **parameter** such as "**interaction-density**" has a maximum **gradient**" (1969, p.201-214).

Furthermore... "The boundary-surface for one property (such as heat-**flows**) will tend to coincide with the boundary surfaces for many other properties (such as blood **flow**, **sensors** endings, physical **density**, and so on) because the surfaces are mutually-reinforcing".

And... "All **gradients** and **flows** in the **region** very near the boundary will tend to be either parallel or perpendicular to the boundary... Evidently in the **region** close to a boundary the strong-**coupling interactions** within the systems are parallel to the boundary while the weaker-**coupling interactions** between the system and the larger **super-system** flow in and cut perpendicular to the boundary" (Ibid).

All this obviously applies to boundary conditions in **social systems**, as for example beehives, anthills, business companies or nations.

A very important observation by I. PRIGOGINE et al. is that: "A sufficiently small system will always be dominated by the boundary conditions – the conditions imposed at the walls of the vessel (note: the authors are referring in this specific case to a chemical reaction. Similar effects are however present whenever boundaries are proportionally very important in relation to surface and volume)." In order for the **non-linearities** to be able to lead to a **choice** between various possible solutions, it is necessary to go beyond some **critical spatial dimensions**. Only then can the system acquire a degree of **autonomy** with respect to the outside world" (1975, p.31). This is because: "In the case of small-size **fluctuations**, boundary effects will dominate and **fluctuations** will regress" (Ibid, p.43).

This aspect is probably the most basic explanation of the universal tendency of systems – natural or artificial – to grow in **size**, at least up to some critical **limit** where the effects of big **size** become preponderantly negative.

Boundary conditions are not necessarily constant. A.S. IBERALL states: "... if boundary conditions of a nonconstant nature are maintained, the system may find a **process** which is either in **steady state** or which is dynamically fluctuating... It has begun to be realized that **fluctuations** and turnover are necessary conditions for the maintenance of **form** (See e.g. the work of PRIGOGINE, KATCHALSKY, MOROWITZ, PATTEE, IBERALL, ZHABOTINSKY)" (1973, p.5).

Such **concepts** were developed as early as 1942 by the French engineer Ch LAVILLE in his theory of **vortexes**.

0324

BOUNDARY (Elusive)²⁾

Fractal boundaries are infinitely complex and seem to dissolve as we try to pin them down more precisely.

This is undoubtedly a feature of existing **complex systems**, but then only up to the point where the **elements** of the boundary dissolve at a lower **scale** in some other type of lesser **elements**.

However, the mathematical **models**, especially their graphic representations, are quite useful to visualize the elusiveness of boundaries, which means that any boundary **element** is simultaneously within the system and within its **environment** (or within neither).

WEIERSTRASS function expresses this characteristic through the impossibility to differentiate for any **value** of the **function** (i.e. to draw a tangent to any part of the curve).

The same principle applies to every **fractal**.

0325

BOUNDARY OF EQUAL ADVANTAGE^{1) - 2) - 4)}

In K. BOULDING's words: "... any **organization** in competition with others will find that its advantage in the **interaction** diminishes as it goes away from some kind of "home base", so that at some point the advantages of any further expansion fall to zero".

BOULDING adds: "... the concept could easily be generalized. It is these boundaries of equal advantage which really define the **niches** of an **ecological system**" (1972, p.69-70).

The respective boundary of equal advantage tends to be more or less geometrically regular for competing or **cooperating** systems, as shown by W. CHRISTALLER and A. LÖSCH (see **hexagonal space filling**).

This seems to be a rather general result of **structuration by dissipation**.

It is also probably related to a problem of length of **lines of communication**, as the distance from the center of the system increases: the possible expansion of political or economic systems must submit to BOULDING's boundaries of equal advantage.

0326

BOUNDARY REGULATION^{1) - 2)}

No boundary is ever absolutely closed, nor completely open. It depends on the **energy flow**, as noted by R.N. ADAMS, in accordance with LOTKA's **Principle of maximum energy flow**: "The distinctiveness and **stability** of the boundaries of a **dissipative process** vary directly with the tendency of that **process** to seek a minimum **dissipation rate**, inversely with its tendency to maximize **energy flux**" (1988, p.149).

As to the **autonomy** of the system it depends at least partly on its ability to close or open its boundary for the purpose of maintaining its **dynamic stability** by regulating its **inputs** and **outputs of energy**.

The study of a variety of systems shows that boundary regulation is partly automatic (by **reflexes**) and partly voluntary. Furthermore the deliberate part of **regulation** grows steadily with the **complexity** through the evolutive **scale** of systems.

As **dynamic stability** results generally from the **cyclical** or **hypercyclical** succession of **states**, boundary regulation depends on the **knowledge** the system has of its own **states**, past, present and possible futures. The heightened **predictability** aptitude in highly **complex systems** goes matched with the increase of the **feedforward** (i.e. willful) capacity for **regulation** of their boundary conditions.

0327

BRAIN^{3) - 5)}

St. BEER described the brain in cybernetic terms as follows: "We have in the cranium a slightly alkaline three-pound electrochemical computer running on glucose at about 25 watts. This computer contains some ten thousand million (that's 10^{10}) logical **elements** called **neurons**, operating on a basic **scanning rhythm** of ten **cycles** per second. Then this is a **high-variety dynamic system** all right; but it really *is* finite. It follows from ASHBY's law that we can recognize **patterns** up to a certain **limit**, and not beyond. Thus if something is going on that involves a higher **variety** than the brain commands, we shall not recognize what it is. This is the old **constraint of requisite variety**" (1974, p.58).

BEER adds the following: "About a quart of blood (about one seventh of the circulation) flows through the brain every minute, and is heated about one degree Fahrenheit. That takes about 25 watts.

"The resting **state** of the brain, called the **alpha state**, is characterized by the **alpha rhythm**, which tends to be **stable** at around **ten cycles**" (p.67).

Of course, in 1974, research on **networks** and **connection machines** was just starting. The **analogies** between the brain and the computer (**digital** or **parallel**, or both?) surely needs still more careful scrutiny.

From another angle, related to the general **organization** of the brain, it would seem that it is at the same time localized (with specific perceptive and active areas), distributed (even a seemingly global **function**, as for instance sight, is the global result of a **synchronic synthesis** of distinct **perceptions** of **limits**, **position**, shape, motion, depth, colors, etc.)... and **hierarchical**, in the sense that, admitting the **modular** character of brain **organization**, brain works in a coordinated way (Philippe LAMBERT on Xavier SERON's cognitive neuropsychology - 1999, p.39-43 - Hemai PARTHASARATHY, 1999, p.29-31).

However "**hierarchical**" does not imply an all powerful and precisely localized organizer. It seems to respond to a kind of **chaotic determinism** through multiple **simultaneous** neuronal **interactions**, within diffuse **limits**, leading to **autopoiesis**

This could better explain **creativity**, **learning**, and also partial readaptation after some disability (as a stroke, for example).

→ **Algorithm (Back propagation); Algorithm (Framing); Algorithm (Iterative refinement); Algorithmization by selection; Information; Nervous system and brain, Memory (Distributed); Taxon memory**

0328

BRAIN and ENVIRONMENT^{1) - 3)}

... or the macrocosm within the microcosm.

According to V.I. KREMYANSKIY: "The brain first developed mainly as an organ of internal **interconnexion**, and then primarily as an organ of **interconnexion** with the **environment**" (1969, 125-46).

In fact, it seems probable that both developments have been simultaneous and complementary all along **evolution**, by a kind of alternating **process of reinforcement**, in relation to ASHBY's **Law of Requisite Variety**.

KREMYANSKIY adds: "This augmented the **dependence** of the **organism** on far more distant and complex **events** in the **environment** (with the development of the **organs of perception** and systems of **receptors**) (p.141).

Man has been speeding up this movement during the last centuries, with the **emergence** of more numerous and complex artificial **means of perception** and interpretation.

However, admitting that the enhanced presence of the **environment** under the guise of **representations** within the brain increases **dependence** it also increases the capacity to handle it, which of course brings forth new hazards.

0329

BRAIN CIRCUITS¹⁾⁵⁾

C. KOCH and G. LAURENT write: "Brain **circuits** are not **Boolean networks**, where **connectivity** is everything. They are not made of static, **linear neurons**, **isotropic nets**, or constant **connection weights**.... A more realistic accounting of the dynamic nature of neuronal ensembles and their nonrandom, inhomogeneous **connectivity topologies** has been incorporated by TONONI and his colleagues into a formal definition of "neuronal complexity" using concepts drawn from **information theory**. These concepts express the degree of **interactions** between **elements** of a neuronal **population**... **Complexity** will be high if a large number of subassemblies of varied sizes can be formed within the population" (1999, p.97).

Further on they add: "The standard **von NEUMANN** computer **architecture** enforces a strict separation between **memory** and **computation**. **Software** and **hardware**, which can be easily separated in a **computer**, are completely interwoven in brains... Furthermore, brains wire themselves up during **development** as well as during adult life, by modifying, updating, replacing **connections**, and even in some circuits by generating new **neurons**. While brains do indeed perform something akin to **information processing**, they differ profoundly from any existing computer in the scale of their intrinsic structural and dynamic **complexity**" (Ibid, p.98)

As stated by the authors, much work will still be needed to reach a better understanding of brain circuits.

→ **Synaptic weights**

0330

BRAIN - EYE LAW³⁾

This law has been proposed by G. WEINBERG in the following complementary form:

"To a certain extent, mental power can compensate for observational weakness;

"To a certain extent, observational power can compensate for mental weakness" (1975, p.96).

The first leg of this law is a result of the existence of conceptual **paradigms** and tested **models** and **methods**, accumulated through **learning**. **Observation** conversely, lead to a renewal of **viewpoints**, eventually conducive to a renewal of abstract **frames**.

0331

BRAIN: its organization¹⁾⁵⁾

The main parts of the brain are the following (for locations see fig.)

The definitions are from J. ECCLES (J.E.)(1977), or from the American Heritage Dictionary (AHD), (1978 ed.)

- Archicortex: the ancient part of the cerebral cortex; it includes the **hippocampus** (J.E. p. 234)
 - Cerebellum: the brain structure responsible for **regulation** and **coordination** of complex voluntary movements (AHD, p. 219)
 - Cerebral cortex: the extensive outer layer of gray tissue of the cerebral hemispheres, largely responsible for higher nervous functions
 - Cerebro-cerebellar pathways: the complex pathways linking the cerebral cortex and the cerebellum in both directions (J.E. p. 234)
 - Cerebrum: the main **structure** of the brain occupying most of the cranial cavity and divided into two cerebral hemispheres (AHD, p. 219)
 - Corpus callosum: the tract of nerve fibers connecting the cerebral hemispheres (J.E. p. 235)
 - Hippocampus: one of two ridges along each lateral ventricle of the brain (AHD, p. 624)
 - Hypothalamus: a deep lying part of the cerebral cortex, concerned in visceral control, f. ex. in relation to temperature, salt, water, food, endocrines, and mood (J.E. p. 238)
 - Medulla oblongata: the nervous tissue at the bottom of the brain that controls respiration, circulation and certain other bodily functions (AHD, p. 816)
 - Neo-cortex: the most recently developed part of the cerebral cortex, composing the cerebral hemispheres (J.E., p. 236) The neo-cortex includes an enormous array of interconnected neurons
 - Thalamus: the massive collection of nerve cells deep to the cerebral cortex, in part concerned with transmission of cutaneous sense to the cerebrum.
 - Ventricle: a small anatomical cavity in the brain (AHD, p.1421)
- A part of the thalamus (called ventrolateral) is specially concerned by the transmission from the cerebrum to the cerebellum (J.E. p. 243)
- This is of course a very simplified and sketchy description of the brain's structures.
- For much better **information** see f. ex. J. ECCLES (1978), J.Z. YOUNG (1978) here also used, or some more recent work, as for ex. R. CARTER (1998)

0332

BRAIN METAPHOR³⁾

As the **hypercomplex system** that it is, the brain is not yet fully understood. This is probably why it has been extensively used as a meta-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

phor for different concepts of **regulating** and **deciding** devices. The **hierarchical** brain metaphor extols the brain as the all powerful chief **controller** and **commander**, who should know and decide about everything.

Another and newer metaphor is the brain as a **learning** and adaptable **network** of **elements**. This seems to be a more adequate **analogy**, but the unifying and regulating powers of **networks** should not be forgotten. It is quite possible that future research into brain physiology could lead us to a still different metaphor or **analogy**, not necessarily incompatible with the existing ones.

Our metaphors should not blind us to some other important facts, as for instance the necessary **connections** of the brain (and other **learning-regulating-deciding** devices) with other critical **subsystems** and their significance.

0333

BRAIN (Triune)⁵⁾

A three levels model of the brain.

This **concept** of a multilevel **organization** of the brain as a **complex system** was developed by P. Mac LEAN, as quoted by A.S. IBERALL: "At its base lies the reptilian brain, in which one might say the **routines** or rituals of higher forms of life are governed and programmed. Surrounding that **structure** is the paleomammalian brain, the limbic **structure**, sometimes referred to as the older "smell" brain. Out of this the governing of the world originating from smell, the worlds of food and sex and aggression are intermingled (and sometimes confused). Finally, at the top emerges the neomammalian brain, the brain of sight, the primate brain, the brain of **cognition** and **language**, and coordination of **language**... What is characteristic of the neocortex is its rapid **response**, particularly to sensory **signals**. It programs at the millisecond **level**. It devotes a considerable part of its capacity to handling optical **signals**" (1975, p.21).

This **model** of the globally integrated brain has also been considerably developed by the French physiologist H. LABORIT (1954 and 1970).

0334

BRAIN-COMPUTER ANALOGY³⁾

It could be said that the superficial analogy between brain and computer which filled the pages of so many popular magazines has considerably obscured the issue of comparison of **artificial** as compared to natural **intelligence**.

Only the introduction of some "deus ex machina" would permit us to sustain such superficial analogy as for example in this statement by N.A. COULTER Jr. "Intelligence may be

defined as the **set** of **software programs** which enable the Supervisor (or Ego) (sic) to acquire, create, and execute application **programs**" (!) (1976, p.36).

Curiously enough COULTER himself adds: "... the self-determinism of brains is one fundamental difference between brains and computers"... but he immediately relapses again into the idea that these self-determined brains depend on "the consent of its Supervisor - Ego" to be "programmed" Where could such a "Supervisor" be located?

More recently, M. BODEN makes, from a different standpoint, the following criticism of the **analogy**: "... current **neural-network models**, for all their likeness to the brain, are significantly unlike brains too. For instance, nearly all involve two-way **connections**, whereas brain-cells send **messages** in one direction only. Any one unit is directly connected to only a few others, whereas the lacy branches of a given neuron usually abut to many hundred of **cells**. **Computer models** contain no **analogue** of the neurochemicals that diffuse widely through the brain. Further, neuro-scientists still know very little in detail about what computations are carried-out by brain-cells, and how" (1990, p.131). BODEN admits however that: "Certainly, the brain is a **connectionist** system" (Ibid).

Somehow, the brain is probably working simultaneously in **parallel** and sequentially, a "trick" that computers have just started to learn.

0335

BRAINSTORMING^{4) - 5)}

A mental exploration technique seeking new ideas through **unconstrained** conceptual **associations**.

Brainstorming tends to break rigid **reference frames** and, using coincidence, open the way to **serendipity** and discovery. It is a collective technique, used by groups interested in considering a **situation** and aiming at producing as many as possible new and creative ideas. It avoids critical stances as inhibitory to **creativity**. On the contrary, it encourages free-wheeling imagination, unfettered by inhibiting, authoritative or logical **constraints**. Its nature is systemic, since it helps to discover and explore hidden **interrelations** in **complex situations**.

The technique, quite popular during the fifties, is now nearly forgotten. It should possibly be reconsidered in more systemic terms, as it can be very useful in **decision making** on a wider **understanding** basis. See for example J. WARFIELD (1994b).

0336

BRANCHING²⁾

A graphical way to represent **hierarchical organization** in **space** or **bifurcating evolution** in **time**.

Branching as a **model** started from the "tree" **metaphor**. But a real tree is no **metaphor** and its main and secondary branches represent stages in its **growth**. Besides, its roots are also branching.

Of course, **organizations** where one commander or manager has **control** over 10 executive officers, each of whom in his turn commands and/or oversees a large group of people do exist, and can be represented by a branching **diagram**. So is a sequence of various simultaneous **operations**, modelled in a **flow graph** in **time**.

Branching thus corresponds to a well specified type of **order** within systems and/or **processes**. It is now formally incorporated in **theory of graphs**

0337

BRANE¹⁾

This shortened neologism for "membrane" has been introduced recently by some authors. Its usefulness remains to be established, specially as an intended generalization.

→ **Membrane**

0338

BREAKDOWN¹⁾

The structural disintegration or functional disruption of a system or **subsystem**.

M. BUNGE distinguishes: "If **integration** fails the system undergoes *structural breakdown*. On the other hand **coordination** concerns the **relation** among either **components** of **functions** resulting in functional **maintenance**. If **coordination** fails the system undergoes *functional breakdown*. There can be **integration** without **coordination** but not conversely. A complex **machine** out of kilter is integrated but not coordinated. On the other hand **organisms** are coordinated and a *fortiori* integrated as long as they live (1979, p.38).

While **machines** can be sometimes repaired, breakdown in **organisms** and **sociosystems** is generally **irreversible**.

0339

BREAKDOWN TIME²⁾

The **time limit** after which a system submitted to **wear** finally gets out of order or is destroyed.

The subject has been reconsidered recently by P. WINIWARTER and C. CEMPEL (1992, p.9-34), according to whom: "...the breakdown time is determined by the internal **structure** of the system and the way of **energy dissipation** inside the system" (p.25). Furthermore: "Every type of **symptoms** of **wear** approaches infinite **value** asymptotically at the **vicinity** of the breakdown time" (p.27).

Living systems, as well as artificially constructed ones have each a more or less characteristic breakdown time.

0340

BREMERMANN's LIMIT^{3) - 5)}

"No **data** processing system, whether artificial or living can compute more than 2×10^{47} **bits** per second and per gram of its mass" (as stated by K. KRIPPENDORFF, 1986, p.8).

G. KLIR writes: "Using the limit of **information processing** obtained for one gram of mass and one second of **processing time**, BREMERMANN then calculates the total number of **bits** processed by an hypothetical computer the size of the Earth within a **time period** equal to the estimated age of the Earth... This imaginary computer would not be able to **process** more than 2.56×10^{92} bits, or when rounding up 10^{93} bits. This last number 10^{93} is usually referred to as BREMERMANN's limit and **problems** that require processing more than 10^{93} bits of **information** are called transcomputational **problems**" (1993, p.44-5)

KLIR adds: "The problem of transcomputationality arises in various **contexts**. One of them is **pattern recognition**... Another **context**... is the area of testing large-scale integrated **digital circuits**". As a result, we need a "science of simplification" to reduce the **problems** of **complex systems** to a manageable size. This is one of the basic aims of **systemics**."

K. KRIPPENDORFF writes that the limit "refers to a self-contained system where the power supply is included in the total mass and where computation is defined as the **transmission** of **information** over one or more **channels** within the system. Recognizing that computation requires **energy** for changing physical **markers** and for recognizing such **changes** in subsequent steps, the limit is obtained from EINSTEIN's relation between **energy** and **matter**, $E=mc^2$, and HEISENBERG's **uncertainty principle**, which specifies the inaccuracy or **noise** in the **measurement** of **energy**" (1986, p.8).

For a suggestive development about "Everything material stops at 10^{100} " see W. ROSS ASHBY (1974, 166-9).

0341

BROWNIAN MOTION^{3) - 5)}

The **random** motion at microscopic **level** of particles suspended in a liquid or a gas.

As stated by P. DAVIES: "Brownian motion is the archetypical, **random** unpredictable **process**. Yet, so the argument ran, if we could follow in detail the **activities** of all the individual molecules involved, Brownian motion would be every bit as predictable and **deterministic** as clockwork. The apparent **random** motion of the Brownian particle is attributed solely to the lack of **information** about the myriads of participat-

ing molecules, arising from the fact that our senses are too coarse to permit detailed **observation** at the molecular **level**" (1990, p.49).

However: "Two major developments of the 20th century have... put paid to the idea of a clockwork universe" (Ibid).

The first was quantum mechanics which introduced **indeterminacy** at the physical micro-level as well as in relation to our possibility of **observation**. And the second one is **chaos** which, while still somehow **deterministic**, rapidly makes even very simple systems fairly **unpredictable**.

Thus, **determinism** cannot be polarly opposed to **randomness**, nor is **unpredictability** simply a result of our imperfect **perceptions**.

0342

BROWNIAN MOTION²⁾

A **Brownian motion** affected by some **constraints**, not sufficient to bring about full **deterministic behavior**.

This **concept** has been introduced by the French biologist P. VENDRYES (1942).

This author gives various examples. One is the register - by himself - of a Parisian taxi driver, who showed the following absolute or relative - **constraints** upon passengers instructions, or whims:

- remain within the **limits** of Paris municipality
- respect one way traffic **signs** and traffic lights
- follow some obliged routes for public transport
- occasional or more or less permanent diversions due to public works
- existence of some focal and thus more frequently asked for destinations: museums, famous monuments, railway stations, hospitals, etc.

A similar **model** was introduced by W.R. ASHBY in 1956 under the guise of **Markov chains** and **transitions probabilities matrixes** - with some quite entertaining examples (1956, Ch.9).

0343

BRUSSELATOR^{2) - 5)}

A general **model** for **cross-catalytic reaction cycles**.

The Brusselator **model** has been created by I. PRIGOGINE's **thermodynamics** study group in Brussels, "as a perfectly acceptable model for the study of cooperative **processes** in chemical kinetics. It plays somewhat the same role as such models as the harmonic **oscillator**..." (G. NICOLIS & I. PRIGOGINE, 1977, p.94). It consists of the following (very simplified) steps:

1. $A = X$
2. $B + X = Y + D$
3. $2X + Y = 3X$
4. $X = E$

X and Y are intermediate molecules in a global sequence through which A and B become D and E. The Brusselator is thus a very fundamental **transformation cycle**. For accurate description and insights, see reference.

0344

BUFFER⁵⁾

A device introduced into a **communication** system to allow asynchronous **communication**.

L. BRIM comments: "A buffer preserves **message** sequences. The buffer discipline is as follows:

- The **sender** may always send a **message**
- The **receiver** may always receive a **message**, provided the **medium** is not empty
- The order of receiving **messages** is equal to the order of sending **messages**" (1992, p.135).

Buffers allow for serialized and ordered **communication**, avoids bottlenecks and, to some extent, **overloads** in **communication channels**.

0345

BUFFER COMPARTMENT¹⁾

"A **part** of a system which acts as a reservoir for incoming **energy**, **matter**, or **information** such that the **inputs** enter the rest of the system with smoothed and averaged characteristics" (T.F.H. ALLEN & T.B. STARR, 1982, p. 263).

The quantities of **energy**, **matter**, or **information** stored in the buffer compartment are at the free disposal of the system. They can be used by **regulatory subsystems** when needed. This permits a **range** of differential **responses** in a changing **environment**, an adaptive **mechanism** sometimes called buffering, and it also opposes wide structural destruction.

0346

BUTTERFLY (LORENZ)^{1) - 2)}

A **chaotic attractor** whose graphical **representation** is similar to butterfly wings.

This **attractor** was discovered by the American meteorologist E. LORENZ. It graphicates the **turbulent sequences** of meteorological variations, submitted to the **stochastic determinism** proper to very **complex systems**. The same type of **attractors** appears in many other **situations** dependent from the **sequence** of **interactions** between various **initial conditions**. More generally, this is a **chaotic attractor**, for which, as stated by R. MAY "arbitrary close **initial conditions** can lead to **trajectories** which, after a sufficiently long **time**, **diverge** widely. This means that, even if we have a simple **model** in which all the **parameters** are determined exactly, long term **prediction** is nevertheless impossible" (1976, p.466).

In a **metaphorical** – but not at all rigorous – way, the so-called “butterfly effect” in weather forecasts says that, if a butterfly flaps its wings somewhere in the States today, it may produce a typhoon in the Eastern Pacific one month later, i.e. a small local initial **effect** may trigger a **snowball effect** eventually leading to a gigantic accumulative **event**, possibly faraway in **space and time**.

0347

BY-PRODUCT¹⁾

A secondary product or **side-effect** of the **activity of a system**.

By-products or **side-effects** are mainly results of the **activities** of artificial **systems**. Save (very significant) exceptions, they are generally damped by the **environment**. However various problems may become serious.

First, while slight **side-effects** or limited quantities of by-products can be absorbed by the **environment**, massive quantities may suffocate it.

Secondly, there is a specific **critical time** lapse for **assimilation** of by-products by the **environment**. A quite obvious case is half-life at a scale of millenia for radioactive **waste** produced by nuclear **energy** utilities.

Thirdly, some synthetic by-products (or even products) are unassimilable by the **environment**, which offers no known **process** to recycle them.

The by-products and **side-effects problems** are typically systemic, because they affect or may affect the whole natural setting, or a large part of it, during very long **periods**.

0348

BYSTANDER EFFECT¹⁾

The effect on other **elements** of some **input** into one **element** in a system.

This effect has been observed in human biological systems where “**cells** that suffer a direct hit from radiation alter the level of gene activity in neighbouring cells” (Jack LITTLE, quoted by R. EDWARDS, p. 22, 1998).

This implies some **communication** between these cells, probably “through chemical messengers” (Ibid.)

Conversely, where there is a **communication link**, a bystander effect is probably possible. A search for **bystander effects** in societies should eventually be rewarding.

0349

BYTE⁵⁾

A set of various **bits**.

The most common is the octet, which permits the identification of one possibility among 256 ($2^8 = 256$). A kilobyte equals to 1024 bytes and a megabyte is one million bytes.

C

0350

CALCULUS FOR SELF-REFERENCE²⁾

This logical calculus has been introduced by F. VARELA as an extension of G. SPENCER BROWN's **calculus of indications** aiming “... to encompass all occurrences of self-referential **situations**” (VARELA, 1975, p.5).

VARELA explains: “This is done through the introduction of a third state in the form of **indication**, a state seen to arise **autonomously** by self-**indication**” (Ibid.).

This third state represents the unavoidable **organizational closure** of the **observer**. In VARELA's words: “... a third, not so obvious but distinct **domain**, of a self-referential **autonomous** state which other laws govern and which *cannot* be reduced by the laws of the dual **domains**. If we do not incorporate this third **domain** explicitly in our field of view, we force ourselves to find ways to avoid it as has been traditional) and to confront it, when it appears, in **paradoxical** forms” (Ibid., p.19).

Known, assumed and well understood self-reference leads to a quite different viewpoint in comparison to unconsciousness of self-reference (see “**Self-reference in logic**”).

For a complete development of this calculus, see VARELA'S reference.

→ **Laws of form**

0351

CALCULUS OF INDICATIONS²⁾

A fundamental arithmetic that forms the ultimate basis of **Boolean** algebra. It has been introduced by G. SPENCER BROWN in his book “**Laws of Form**” (1969, 1979).

F. VARELA states: “By succeeding in going deeper than **truth**, to indication and the laws of its form, he has provided an account of the common ground in which both logic and the **structure** of any **universe** are cradled, thus providing a foundation for a genuine **theory of general systems**” (1975, p.6).

BROWN's calculus of indications starts from the ideas of **indication** and **distinction** as “...a necessary condition for an act of **indication** is the drawing of a **distinction**. The **form** (**paradigm**) of **distinction** is taken as *the form* (**paradigm**). All other **forms** (**paradigms**) are taken out of (follow from) *the form*” (R.A. ORCHARD – 1975, p.102).

“A **state** distinguished by the **distinction** is marked with the mark 1 and the **state** is called the marked **state**” (Ibid.).

Arrangements (i.e. combinations) of marked and non-marked **states** and the use of a directional barb allow for the development of the whole of calculus of indications.

0352

CANTOR SET (Triadic)²⁾

This set, imagined by Georg CANTOR towards the end of 19th century is probably the first ever abstract **representation** of a **fractal** set.

It is constructed, starting from a segment, which is divided in three equal parts, the middle third being removed. This operation is renewed on the two subsisting segments ad infinitum (supposedly!). In this way, we should obtain finally an infinity of points... whose total length dimension, or linear measure, would be zero. The Cantor triadic set has a fractal dimension of 0.63. Another Cantor set can be constructed removing at each stage two fifth segments within the remaining part of the original segment. It has also a zero linear measure and its **fractal dimension** is 0.68.

The Cantor set is **self similar**.

If we could invert the construction **process** of the Cantor set (i.e. from an infinity of points to a complete segment) we would have modelled the genesis of a macrolevel **system** constructed from discrete **parts**.

Other mathematical objects of the same type are the “snowflake” Koch curve, and the Peano curve, made from an infinitely folded segment which finally would wholly cover a surface. There are also objects of the same kind in three or more dimensions.

0353

CAPSULATION^{1) – 2)}

The enclosure of a number of hitherto independent **elements** within a common **boundary**.

Such an **event** is generally a result of some kind of pressure within the common **medium**. The more or less accidental concentration of numerous **elements** in a reduced **space** produces **crowding** and, due to the increasing closeness of the **elements**, these start to interact, whether being of the same or of different types. The boundary defines an incipient internal **space**, in opposition to, but in **communication** with the external one, i.e. defines an **invironment** and an **environment**.

A near synonym also used is “**encapsulation**”

0354

CARRYING CAPACITY¹⁾

1. “... The **population level** for long-range survival” (H. ODUM, 1983, p.125).

2. “The maximum number of living things that can be supported indefinitely by a given **eco-system** or area without deterioration” (UNESCO-UNEP Glossary, 1983, p.7).

These definitions are proper to **ecology** and related to basic physical **resources** (mineral **cycles**, soil, water **levels**, plants, etc.) However there are also **limits** to the carrying capacity of **transmission channels** of any kind.

An eventual larger carrying capacity must be "based on the continued **flow** of the concentrated potential **energy**" (ibid., p. 123).

The carrying capacity of any **biotope** or **ecosystem** remains stable only when the **environmental** conditions remain within stable **limits**. This does not exclude some more or less periodic maxima or minima, for example during winter, or dry season. Very long term **constraints** are more elusive and, as a result, long range carrying capacity is quite difficult to evaluate with reasonable certainty.

Still another definition is the following: In any **subsystem** – but particularly in a **niche** in an **ecosystem**, the ultimate **limit** to the number of **elements** or individuals able to survive in the **niche**.

The ultimate limit is generally characterized by heavy **overcrowding**, which leads to blockage (for instance in vehicles traffic on trunclal roads), massive destruction (by **epidemics**, for example), massive emigration (as the one caused by overpopulation and the potato blight famine in the 1840's in Ireland) or gregarious **mutation** and **behavioral change** (as in **Dicystelium discoideum** or in solitary locusts reaching a **critical density**)

0355

CASSANDRA'S SYNDROME ¹⁾⁴⁾

The fate of any clear-sighted individual, able to **forecast** some future **event**, but nearly never believed. This was the case of Cassandra, daughter of King Priam of Troy, who was endowed with such a gift, but fated by the god Hermes never to be given heed. (Homer's Iliad)

The syndrome is in fact systemic and specific to social systems. Some very few individuals are endowed with foresight because they perceive quite concealed and unobtrusive **interactions** in a **situation** or **issue**, that could later on trigger very considerable and possibly dramatic consequences. Meanwhile, common people remain shortsighted and, as they see nothing special in the situation, they don't believe "Cassandra".

Another curious greek tale, more or less similar, is about Tiresias, the Theban prophet, who was blind. In many cases, the foresighting individual seems to be blind to the present issue, as his forecasts or prophecies appear to be incredible according to what common people perceive from the actual facts. Tiresias also is thus not understood or believed.

Let us hope a better fate for systemists concerned or worried about the future of human systems!

→ **Interception; Prospective**

0356

CATABOLISM ¹⁾

The **process** of dis-**assimilation** and emission or elimination of products by a **living system**.

The catabolic **process** includes the following phases:

- **Production**: the synthesis within the system of specific material or energetic products destined to be exported as **outputs** into the **environment**.

- **Encoding**: the **recoding** of internal **information** into a public **code** in order to produce **information** that can be interpreted and used by other systems (specially in **human systems**).

- **Output transduction**: The translation of the prepared products from the system through its **boundary** into its **environment**.

Not all products – specially those of **human systems** – are innocuous for the **environment**. Some, as for example long life radioactive **wastes**, cannot even be artificially **recycled** in an efficient manner.

For the respective **roles** of the **subsystems** concerned in catabolic **processes**, see J. MILLER's **20 critical subsystems**.

The process of absorption and **assimilation** of **inputs** by a system is called "**anabolism**", while "**metabolism**" is the generic term for the whole **process** of absorption, **transformation** and emission of **matter**, **energy** and **information**.

In a more or less **analogic meaning**, higher **level living systems** (groups, enterprises, **organizations**, **communities**, etc...) all catabolize specific **outputs**.

0357

CATALYSIS ^{1) – 5)}

The recurrent action of an **element** in a system, which activates some **process**.

This is a systemic extension of the classical chemical **model** of catalysis.

M. ZELNY observes that "...it is unreasonable to assume that the catalyst is unaffected by its participation in the production of **links**. Each single act of production diminishes its catalytic power. Initially, when there is a lot of free substrate, the number of produced **links** is naturally very high. At the same time, the number of holes necessary for **disintegration** is still very low" (1977).

However, the catalyst uses up the **substrate** and, as a consequence, finds less opportunities to act. It is its own **activity** which limits, and finally suppresses its capacity for **activity**.

This seems to open avenues for the explanation of what ZELNY calls "built-in death" of **autopoietic organizations**.

0358

CATALYSIS (Auto-) ²⁾

"**Cycle** where a product of the reaction catalyzes its own synthesis" (LASZLO 1992, p.242).

This is the simplest type of catalysis.

It may lead to a **runaway process** in the case of an unchecked multiplicative reaction. However, auto-catalytic processes are generally inserted in more complex **hypercycles**, organizationally closed.

As stated by G. PASK, the concept "is used in **cybernetics** in connexion with all kinds of **change** in the **state** of the system" (PASK, 1961, p.114).

Other authors use the term "**Self-Catalysis**" in an apparently similar sense (see hereafter).

0359

CATALYSIS (Cross-) ²⁾

"**Cycle** where two different products (or groups of products) catalyze each other synthesis" (E. LASZLO, 1992, p.242).

LASZLO observes that cross-catalysis leads to catalytic **cycles** or **hypercycles** and "tend to be naturally selected in the course of time by virtue of their remarkable **stability** under a wide range of conditions." (ibid)

He adds: "The formation of cross-catalytic **hypercycles** allows dynamical systems to emerge on successively higher **levels of organization**" (ibid., p.244).

0360

CATALYSIS (Self) ²⁾

Reproductive **process** of complex **elements**, by the ordering action of some of their **parts** on simpler **elements** already present in their **environment**.

According to J.de ROSNAY: "A peculiar form of **fluctuations** which plays a fundamental role in the genesis of an organized **structure** is the self-catalytic reaction. There is self-catalysis when products of a reaction act as a catalyzer in this same reaction. A self-catalytic reaction may lead to the **emergence** of a **structure** ordered out of an **homogeneous medium**. It is the case of a **chain reaction** which produces (by **random** molecular collisions) a more complex molecule capable to **catalyze some stages of its own formation**. The chain closes on itself and produces a **positive feedback** starting from simpler molecules already present in the **medium** and available as building blocks. The complex molecule builds itself and the **process** accelerates with the help of the just created products" (1975, p.227).

This **process** is active in the DNA and RNA chain of reproduction... and thus in the reproduction of superior **organisms**.

It plays also a role in the autopoietic **process**. Self-catalysis is an important mechanism for the **emergence**, multiplication and **stabilization** of **complex systems**.

0361

CATASTROPHE ^{2) – 3)}

The sudden **transition** of a **trajectory** from one **basin of attraction** to another.

In terms of H. and L. SABELLI: "Catastrophes are the simplest forms of **bifurcations**, i.e. the **transition** from one **point attractor** to another (i.e. **choice** or rejection). The simplest catastrophes are governed by only two **control** variables: a) **asymmetric**, which at mid values is associated with large **changes** between the opposite **modes**, while at extreme values is associated with small **changes** around the **modes**; and b) **bifurcating**, which at low values is associated with **continuous** outcomes and at high values, with a **discontinuous** outcome" (1992, p.663).

0362

CATASTROPHE (Delayed)²⁾

A catastrophe occurring after a long and slow **accumulation** of small **effects**.

These catastrophes have been discussed by M. KARSKY (1993, p.1413-21). This is a very dangerous type of **phenomena**, in natural as well in artificial systems. Small **individual effects** are generally irrelevant, and perceived as such. But, as shown by KARSKY, the damped **oscillations** they provoke can suddenly "jump out of the track" and lead to new and unexpected **macroscopic** qualitative **effects**. KARSKY observes that: "this **phenomenon** takes place only in a very narrow band of **parameters** variations and may easily pass unnoticed in absence of a systematic policy of **simulation** through multiple **scenarios**. It could however explain in some cases the occurrence of seemingly inexplicable catastrophes" (p.1417).

That the **accumulation** be slow implies another danger: the **nonperception** of the progressive buildup of a **macroscopic change** in the making. When finally it becomes evident that a dramatic **change** is to occur, it is generally too late to do something about it.

→ **Cycles and Effects (Delayed)**

0363

CATASTROPHE THEORY^{2) - 3)}

"A **topological** theory describing the **change** of a system's **structure** along a **continuous morphogenetic** landscape, including occasional jumps" (K. KRIPPENDORFF, 1986, p.9).

In R. THOM's, founder of the theory, words: "It gives a kind of local description of a system within a **control parameters space**. One may modify the **controls** on the basis of a certain system of **values** and describe, through the choice of convenient surfaces in this **space**, the **continuous variations** and the occurring **catastrophes**" (1993, p.30).

THOM thus defines the elementary catastrophe: "Any **conflict situation** between local **regimes**, potential minima, which may occur in a stable manner on the four dimensional **space-time**" (1974, p.71).

K.B.DE GREENE states: "Catastrophe-theoretic **models** deal with systems that show **multiequilibrium behavior** and usually show a path **irreversibility (hysteresis)**" (1990, p.55).

Catastrophe theory is a formalized geometrical theory that cannot even be sketched within the limits of this work (see R. THOM's, E.C. ZEEMAN's and T. POSTON and I. STEWART's references) Let us only try to describe its nature and the wide scope of its applications, as well as to warn against its improper **metaphorical** uses.

T.F.H. ALLEN and Thomas B. STARR explain it as: "A theoretical construct used for the description of certain types of disjunct **behavior**. It derives from a **topological** consideration of folded surfaces describing the **interactions** between **variables**. Catastrophe theory is rather specific in its appropriate application, although it serves a more general usefulness as a mathematical **metaphor**" (1982, p. 263).

F. HEYLIGHEN observes: "It was developed by R. THOM (1975) in order to model the (**continuous**) **development** of (**discontinuous**) forms in **organisms**, thus extending the much older work of the biologist D'ARCY THOMPSON (1917)" (F. HEYLIGHEN, 1997, p.33).

Catastrophe theory is undoubtedly a systemic one, since it addresses to a wide field of general **phenomena**, starting from a qualitative **topological** view and giving them a common basic ground through **isomorphic models**. It is basically a theory of **discontinuous phenomena**, related to sudden **phase transitions**, marking a jump from one **attractor** to another. It is closely related with the following topics: **Field gradients** leading to **singularities**; **markovian systems** and **LIAPOUNOV stability**; **bifurcations** and **unfolding**; **morphologies** and **morphogenesis**; and the different corresponding **attractors**.

The best known part of catastrophe theory are the seven basic elementary catastrophes, upon which according to THOM a general catastrophe theory is to be built upon. (in ZEEMAN, 1977, p.633)

The seven elementary catastrophes (a synthesis of THOM's (1974) and ZEEMAN's (1977) presentations):

	Dimensions		Typical Phenomena
	of state space	of control space	
a) Cuspoids			
Fold	1	1	No dynamics
Cusp	1	2	Hysteresis, breakdown, sudden regime change, phase transition
Swallowtail	1	3	Conflict between two regimes
Butterfly	1	4	Stability in a zone through equilibra- ted forces

	<u>Dimensions</u> <u>of state of control</u>		<u>Dimensions</u> <u>Typical</u>
	<u>space</u>	<u>space</u>	<u>Phenomena</u>
b) Umbilics			
Hyperbolic	2	3	breaking waves
Elliptic	2		3 submitted to an organization center
Parabolic	2	4	Surface penetration with break-through

Graphical **models** have been produced by THOM (1972).

Numerous applications of the elemental catastrophes have been proposed in physics and chemistry (the relation to **dissipative structuration** and **bifurcations in far from equilibrium systems** is still a fuzzy area); in engineering; in biology and embryology; in animal and human ethology; in psychology (**perception** and **behavioral** shifts) and in social sciences (economics, markets shifts).

However, J. CASTI observes that there have been "... attempts by practitioners to use the theory as a vehicle for **predictions in situations** where it can at best be used only to explain" (1994, p.48).

In effect, in some cases – undoubtedly and at least partly due to the "mediatic" name given by THOM to his theory – the catastrophe **models** became a somewhat misused and abused **metaphor**.

0364

CATCHMENT^{1) - 2)}

The incorporation by a system of some formerly independent **elements** or systems.

Catchment is in fact a **process** of expansion of the **attractor basin** of the system, corresponding to the expansion of its **field** of influence.

A typical example is the catchment by a river **basin** of some adjacent area.

0365

CATEGORIES FORMATION³⁾

According to D. BOHM and F.D. PEAT: "... categorizing involves two actions: **selection** and collection. According to the common latin root of these two words, *select* means "to gather apart" and *collect* means "to gather together"...

"The second phase of categorization is that some of the things that have been selected (by virtue of their difference from the **background**) are collected together by regarding their differences as unimportant while, of course, still regarding their *common* difference from the **background** as important" (1987, p.112).

All dogs are selected in the animal taxonomy, possibly together with cats and horses, as distinct from, let us say, marine mammals. Thereafter, we collect them in the family canidae, and more specifically in the species *canis*, in order to distinguish them from any other mammals.

Systemic categorization, while essentially the same, may be used in an inverse way: we abstract very general categories, that can be used to launch **transdisciplinary** bridges. The **hypercycle**, for instance, as a generalized systemic **model of catalysis**, may be observed as a **process** in numerous systems of very different classes: cyclical chemical reactions, enzymatic reactions in **living systems**, complex **autopoiesis** in **social systems**.

→ "Structural differential".

0366

CATEGORIES (Relativity of)³⁾

According to BERTALANFFY: "The categories of experience or forms of intuition, to use KANT's term, are not a universal a priori, but rather they depend on the psycho-physical **organization** and physiological conditions of the experiencing animal, man included. This relativism from the biological standpoint is an interesting parallel to the relativism of categories as viewed from the standpoint of culture and **language**" (1962, p.75).

We are indeed enclosed in a "observational bubble" from both viewpoints and we should thus carefully practice **ontological scepticism** and **hypothetical realism**.

In G.M. WEINBERG's words: "The most dangerous pitfall in developing category systems is imagining that one system of **paradigms** is more "real" than another" (1975, p.34).

0367

CATEGORIZATION¹⁾³⁾

"The ability to group **objects** and **concepts** by their relative **similarities** or differences" (M. CAUDILL, 1994, p.18)

Isomorphisms and **homomorphisms**, as well as **metaphors**, are depending on initial categorization.

0368

CATEGORY³⁾

A defined **class** in a system of **classification** of **objects**, **processes** or **relations**.

J.A. GOGUEN and F. J. VARELA write: "The intuitive idea of a category is that it embodies some **structure** by exhibiting the **class** of all **objects** having that **structure**, together with all the **structure** preserving **mappings** or **morphisms** among them" (1979).

R. ROSEN introduced a systemic concept of "category", also different from the one traditional in philosophy, and more formal:

"... a category consists of the following data:
1. A collection of **objects**, which we shall design by A, A',...

2. A function assigning to each pair (A,A') of **objects** in the category, a **set** denoted by H(A,A'), the **elements** of which are called **mappings** or **transformations**. This **set** may be empty for some pairs (A,A').

If $f \in H(A,A')$, then we shall call the **object** A the **domain** of f; the **object** A' will be called the **range** of f." (1960, p.46)

ROSEN also introduced the concept of sub-category, within a previously defined category and stated "... the **objects** and **mappings** of a sub-category themselves comprise a category" (p.47).

The preceding notions give the bases for a formally organized **taxonomy** of systems and **subsystems**, and has been introduced by ROSEN for the "**Representation** of biological systems".

0369

CATWOE²⁾

"A mnemonic of the six crucial characteristics which should be included in a well-formulated **root definition**" (in **Soft System Dynamics Methodology**) (R. RODRIGUEZ ULLOA, 1999).

The six crucial characteristics are:

Actor: A person who carries out one or more of the **activities** of the system.

Customer: A beneficiary or victim of the system's **activity**.

Environmental constraints: The external impositions which the system takes as given.

Owner: The individual who find himself in the problem **situation** and could modify or destroy the system.

Transformation process: The core **transformation process** in a **human activity system**, which can be expressed as the conversion of some **input** into some **output**.

Weltanschauung: The (unquestioned) **image** or **model** of the world which makes this particular **human activity system** (with its particular **transformation process**) a meaningful one to consider.

The CATWOE characteristics were originally introduced by P. CHECKLAND

0370

CAUSAL EXPLANATION³⁾

HUME, as quoted by F. DAVID PEAT (1987, p.40), wrote: "We have no other notion of cause and **effect**, but that of certain **objects** which have been *always conjoined* together... We cannot penetrate into the reason of the conjunction". Elaborating on HUME, PEAT concludes: "The chain of linear **causality**, therefore, is a mixture of **habit**, belief, and common sense. But this common sense is based on a number of assumptions, namely:

- That two **events** are unambiguously separated from each other and have their own independent existence, as, for example, two bodies with well defined **boundaries**.
- That some contact, force, or influence flows from one body or **event** to the other.

- That there is a clear **flow of time** with the cause occurring in the past and the effect in the present" (p.41).

The spanish philosopher J. MARIAS writes: "... causal explanation has to be schematic and universal, leaving out the concrete individuality, which is the most real part of the thing explained" (1975, p.145).

As stated by R. LILIENFELD: "... logical or pseudo-logical schemes ... gain manipulability at the cost of reality" (1979, p.5).

In PEAT's terms, the supposed **chain of causality** is "in fact a complex **network of causality**". And "The more the **limits** of this **network** are extended, the more it is seen to stretch out over the entire earth and ultimately the universe itself" (p.45). We are thus faced with two **practical** problems when we want to **construct causal models**:

- Where to fix reasonably – i.e. on the base of a sufficiently **global information** – the **limits** of the **network** related to the system, **situation** or **phenomenon** we seek to modelize? ("To talk of planetary influence on a game of tennis is obviously far-fetched" (p.45) – But possibly not so the effects of planetary temperature increase on investment at a sea-side resort at a 30 years **time lapse**.
- How much should we extend the **network** into the past, admitting that we can obtain reliable **information** For example, using historical and geological **information** about the Mississippi flood plains.

E. JANTSCH equates causality with **local determinism**, "... often effective in describing microaspects of **change** in a nonsystemic and short range perspective. Newtonian mechanics belongs here as well as many predictive cause/effect **models** in the social domain" (1975, p.98).

(POINCARÉ's **three bodies problem** shows that Newtonian mechanics with all its achievements, is indeed a simplified view of celestial mechanics).

Complex systemic **models** are still **models**, but at least, they aim at a more complete **description** of real entities. To construct such **models** we are in need of **cybernetic** and systemic conceptual means, able to reflect a higher degree of **complexity**. New logical and mathematical formalisms are also required, as for example SPENCER BROWN's Laws of form; ZADEH's **fuzzy sets**, or LORENZ, SMALE's et al, **deterministic chaos**.

We thus end up with, in A. ARIELY's words: "... an album of **maps** to be studied not as an ultimate truth, but as way-points that the applicator can use provided that he verifies the **model** by his intuition, imagination and the conditions of the problem at hand" (1979, p.12).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0371

CAUSAL LOOP ¹⁾ - ²⁾ - ³⁾

A **cause** and **effect** relation closed on itself.

A causal loop is the result of a **feedback** of the **effect** upon the **cause**. **Interconnected** causal loops may become very complex. This **model** has been extensively explored by M. MARUYAMA (1994, p.75-87).

The **feedback** can also take the form of a **circular** and **cyclical** chain of **feedbacks**. It can reduce, maintain or amplify the **process**.

MARUYAMA explains: "The **dynamics** of causal loops has two aspects: quantitative and qualitative. The former is a matter of **change amplification** and **change** counteraction; the latter deals with **heterogeneity** and interrelations among **heterogeneous elements**, as well as the creation of new **patterns** and inventive **processes**" (p.75).

At the beginnings of **cybernetics**, much emphasis was on reducing or stabilizing causal loops. This is still the case in some disciplines. In MARUYAMA's words: "Causal loops have become invisible in the **black box**, and we have fallen back on loopless **input/output relations**". LEONTIEFF's **input/output matrixes** in economic theory are a typical case.

MARUYAMA moreover observes that: "Economists tend to ignore **change-amplifying** causal loops and believe in **equilibrium** or the **cycle** almost superstitiously" (p.75). See "**Economics in systemic terms**".

MARUYAMA offers a causal loops notation with the needed explanations (p.76-80). He insists on the importance of **initial states**, **reversal effects** and of **time delays**.

see figure below

Figure: see entry **CAUSAL LOOP**

Causal loops: an example

From H. T. ODUM: 1971, p. 36

0372

CAUSAL PROCESS (Mutual) ¹⁾ - ²⁾

This model was introduced by M. MARUYAMA in 1963. He observed that the classical **model** of **cybernetics** was "focusing on the **deviation-counteracting** aspect of the mutual **causal relationship**, (but that) cyberneticians paid less attention to the systems in which the mutual **causal effects** are **deviation-amplifying**". He noted that the latter: "... are ubiquitous: **accumulation** of capitals in industry, **evolution** of **living organisms**, the rise of cultures of various types, interpersonal **processes** which produce mental illness, international **conflicts**, and the **processes** that are loosely termed as "vicious circles" and "composed interests"; in short, all **processes** of mutual **causal relationships** that amplify an insignificant or accidental initial kick, build up **deviation** and **diverge** from the **initial condition**" (p.233).

He called the study of these **processes** "the second **cybernetics**" (not to be confused with von FOERSTER's **cybernetics of 2d order**). He observed that: "The **deviation-counteracting** mutual **causal process** is also called "**morphostasis**", while the **deviation-amplifying** one is called "**morphogenesis**" (Ibid).

The similarities with various **processes** and **models** discovered later on is evident: **dissipative structuration**, **bifurcations**, **sensibility to initial conditions**, and **chaos**.

He stated, for example: "... when the **deviation amplification** mutual **causal process** is combined with **indeterminism**, here again a revision of a basic law becomes necessary. The revision states: A small initial **deviation**, which is within the **range** of high probability, may develop into a **deviation** of very low probability (or more precisely, into a **deviation** which is very improbable within the **framework** of prob-

abilistic unidirectional **causality**). Not only the law of **causality**, but also the **second law of thermodynamics** is affected by the **deviation-amplifying** mutual **causal process**" (p.234).

MARUYAMA proposed the following simple **model** of the **deviation amplifying** mutual **causal process** (practically a **cellular automata**, complete with graphic **representation**):

"Let us imagine, for the sake of simplicity, a two-dimensional **organism**. Let us further imagine that its cells are squares of an equal size. Let us say that the **organism** consists of four types of **cells**: green, red, yellow and blue. Each type of **cell** reproduces **cells** of the same type to build a tissue. A tissue has at least two **cells**. The tissue grows in a two-dimensional **array** of squares. Let us give a **set of rules** for the **growth** of tissues:

"1. No **cells** die. Once reproduced, a **cell** is always there.

"2. Both ends of a tissue grow whenever possible, by reproducing one **cell** per unit time in a vacant contiguous square. If there is no vacant contiguous square at either end, that end stops growing. If there are more than one vacant contiguous squares at either end, the direction of the **growth** is governed by the preferential **order** given by rules 3,4, and 5.

"3. If, along the straight line defined by the end **cell** and the penultimate **cell** (next to the end **cell**) there are less than or equal to three **cells** of the same type (but may be of different tissues) consecutively, the preferred direction is along the same straight line. If that direction is blocked, follow rule 5.

"4. If, along the straight line defined by the end **cell** and the penultimate **cell**, there are more than or equal to four **cells** of the same type (but may be of different tissues) consecutively, the preferred direction of **growth** is a left turn. If a left turn is impossible, make a right turn.

"5. If, when a straight **growth** is preferred, the straight **growth** is impossible because the next square is already occupied, do the following. If the square to which the straight **growth** would take place is filled with a **cell** of the same type as the growing type, make a left turn. If the square ahead is filled with a **cell** whose type is different from that of the growing tissues, make a right turn.

"6. The **growth** of the four types of tissues is timewise out of **phase** to each other: green first, red second, yellow third, and blue last within a **cycle** of one unit of **time**" (p.237).

MARUYAMA's **rules** are practically **framing algorithms**.

A very important feature of the **model** is the **initial state**, i.e. the disposition of the first four units on the grid (MARUYAMA's "initial kick"). And, of course, the player is furnishing the **energy** for the **process** of construction.

(This kind of graphical experience is much less complicated in practice than would appear by reading the rules).

MARUYAMA's graphics are self-structuring, i.e. *self-constraining*, in accordance with the chosen rules, which may be widely varied. This is very significant for **concrete systems**, which are always based on ruled **interrelations** between some more or less reduced types of **elements**. CONWAY's **games of life** are of the same kind, even if based on quite different rules.

→ **Positional value**

0373

CAUSALITY³⁾

The **link in time** between two **events** such as the first one is necessarily followed by the second one, through some well defined **process**.

This is the classical, strictly **deterministic** concept of causality. The first **event** is generally supposed to be *the only* cause of the second one, or at least its principal and overwhelming cause. Moreover, this **relation** must be verified each **time** the second **event** occurs after the first one. This implies some well defined and invariable sequence in a characteristic **process**.

This classical oversimplification of the Aristotelic concept of causality, useful as a first approximation and for prediction, has been now widely reconsidered and refined in **systemics** and **cybernetics** (see hereafter).

For a recent wide-embracing reconsideration of the multiple hues and shades of the concepts of **cause** and causality, see Chr. HARDY (2001, p. 44-55)

0374

CAUSALITY (ARISTOTELIAN)¹⁾³⁾

Just as a useful general reference, the four basic causes Aristotle used to answer all "why?"-questions are remembered hereafter:

- material cause
- efficient cause
- formal or formative cause
- final cause

→ **Causality; Determinism; Random processes; Randomness; Time**

0375

CAUSALITY (Circular)

→ **Causality (Cyclic)**

0376

CAUSALITY (Cyclic)^{2) - 3)}

"A cyclic causal **relationship** (is)... a **sequence** of coupled cause-effect **relationships** that leads back to its starting point: A - B - C - ...A" (HEYLIGHEN, 1989, p.374).

However "It is only possible to move toward the future, not toward the past" (p.375). Thus, cyclic causality does not imply **reversibility**. Or, as stated by HEYLIGHEN: "If a distinguishable **change** has occurred, then at the global **level** (i.e. the **level** where all observed **distinctions** are taken into account), there was no real causal cycle and it is possible to define an absolute ordering between all the **events** in the causal chain" (p.377).

To avoid this type of **ambiguity**, it should probably be advisable to avoid the voice "Cyclic causality", or even "Circular causation" (as observed by R.N. ADAMS - 1988, p.68) and to speak, for example of "causality by recurrent **feedback**".

0377

CAUSALITY (Limits to)³⁾

F. HEYLIGHEN states: "Causality appears to be a local concept, which can be used to describe certain aspects of certain **processes**, but which cannot be simply generalized in order to build an encompassing, **deterministic** and reversible theory, such as classical mechanics. In other words, general **processes** are only partially causal. They only conserve certain **distinctions**, perhaps only during a limited **time interval**" (1989, p.372).

We should first remember that past and present **events** have been univocally determined: they occurred in one and only one manner, as a result of a concatenation of some or many concurrent **causes**.

Before their occurrence, they were only partly and conditionally predictable, which is the case of all future **processes**.

0378

CAUSALITY (Linear)^{2) - 3)}

A causal relation without **feedbacks**, in which cause comes always "before" and **effect** "afterwards".

This is the classical concept of causality, of strictly **deterministic** character, allowing perfect **predictability**. It implies the absolute, or for practical purposes, near absolute **stability** of the general **environment** of the **process** inside and outside of the system ("Et ceteris paribus").

While, in E. JANTSCH's words: "It is frequently efficient for the description of **changes** in a non-systemic and short term perspective" (1975, p.118), it is also frequently more or less useless for complex and/or **long term forecasting**.

0379

CAUSALITY (Multiple)¹⁾

The existence of various **simultaneous** and concurrent causal lines in a **complex system**.

Multiple causality is closely related with the very nature of **complexity**. In a **complex system**, a number of different **processes** must take place at any instant, and the **effects** constantly interfere with each other in varying ways. This generates a kind of global **determinism**, but with some, or much, leeway for specific **processes**. The only basic **constraint** is that none of these should infringe the general conditions necessary for the **survival** of the system.

Important consequences are that very numerous combinations of **interactions** are normally possible among the various **processes**, and that their **simultaneous** character, combined with different **time lags**, lead to some **instability**, or possibly to an **ergodic**, or even **chaotic behavior**.

→ **Ergodicity and Homeostat**

0380

CAUSALITY (Mutual)^{1) - 2)}

The **interactions** between two or more **processes** in such a way as that anyone evolves in a way conditioned by some or all of the others.

The **concept** has been introduced by M. MARUYAMA (1968). Mutual causality **processes** evolve from some initial **situation** through the **operation** of specified **rules** within a limited or unlimited **space**. They are generally **pattern-forming** and are closely related to **cellular automata** and **self-organizing networks**. See: "Causal process (Mutual)".

Some mutual causality **processes** can be self-limitating, while other can become **cyclical** or lead to a **runaway event**.

When mutual causal **relationship** appear between more than two **elements**, a multi-loop mutually causal system may develop.

0381

CAUSALITY (Principle of absolute)³⁾

1) All **distinctions** are **invariant**.

2) "All causes of an **event** are predictable if the **states** of the system and the **behavior laws** are known" (K. KORNWACHS & W.von LUCADOU - 1989, p.135).

The principle may be considered as the basic axiom of classical **determinism**. However, according to KORNWACHS and von LUCADOU: "The principle of **determinism** implies that every **event** has its special causes. There is no **event** within the system without any cause" (Ibid).

F. HEYLIGHEN explores some of the foundations of the causality principle in the following way:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"Objects are supposed to have an **invariant identity**. During their movement they do not disappear or merge with other **objects**, and no **objects** are created out of the void or by the breaking up of existing **objects**. In other words, the **distinction** between **object** and **background** is always conserved

"The attribution of a predicate to an **object** is objective, and all **observers** are supposed to agree on it. Hence, the **distinction** between having a property or not having it is also **invariant**.

"The same apply to propositions that are either true or false, independently of the **observer**, and to the **time** ordering of two **events**, which are either simultaneous, or the one precedes the other one. Hence, propositional and temporal **distinctions** are also **invariant**.

"Again the same principle applies to **dynamical constraints**: A **transition** is either allowed or not allowed, without any **ambiguity**.

"Finally the principle applies to state **trajectories**: Two **trajectories** starting at distinct **states** at a certain instant will always remain distinct and have always been distinct".

In conclusion, all **distinctions** between **objects**, between predicates, between different **trajectories**, between **truth** and falsity, between past and future, between possible and impossible, are **invariant**; they remain the same for all times and for all **observers**. This absolute **distinction** conservation can be taken to be the defining characteristic of the classical way of **representation**.

"...each of the nonclassical **representation** can be characterized by the nonconservation of a particular type of **distinctions**" (1990 a, p.434-5).

These basically **ontological** assumptions are very old in the occidental philosophical and intellectual tradition, being already present in Plato (The myth of the Cavern). It has been historically very useful, because it permitted the establishment of the basic sciences of **macroscopic** simple **processes**. But it has been a hindrance to the understanding of **complexity** and the consensual nature of **knowledge**.

HEYLIGHEN concludes: "...the classical **representations** are the result of a completely closed **observation cycle**. The **state** of the system can be perfectly prepared by the **observer**, the **evolution** of prepared **states** in the system is completely causal, the new **states** of the system can be perfectly detected, and the **observer** is supposed to possess all **information** and **knowledge** needed to predict or explain the detected **states** of the system (this is the assumption of perfect, "unbounded" rationality)" (p.435).

This **causalism** is practically a metaphysical stance and has been the dominant **paradigm** of classical science since NEWTON. It implies an overly simplifying **ontological determinism**, which is now in process of deep reconsideration. (see f. ex. M. BUNGE's work - 1979).

0382

CAUSATION (Downward) ¹⁾ - 2)

D.T. CAMPBELL introduced this **concept** in the following way: "Where natural **selection** operates through life and death at a higher **level of organization**, the laws of the higher-level selective system determine in part the **distribution** of the lower-level **events** and substances. **Description** of an intermediate-level **phenomenon** is not completed by describing its possibility and implementation in lower-level terms. Its presence, prevalence or **distribution** (all needed for a complete explanation of biological **phenomena**) will often require reference to laws at a higher **level of organization** as well... All **processes** at the lower **level** of a **hierarchy** are restrained by and act in conformity to the laws of the higher **levels**" (1976, p.87).

Since the higher **levels** were as well somehow constructed from **bottom up**, the following comment from R.N. ADAMS seems important: "That characterization... somewhat obscures the **self-organizing** quality of the **process**. The issue is more one of **control** than of causation; and it is not simply "downward" since it also involves the **feedback** from the subassemblages to the center" (1988, p.153).

0383

CAUSES AND CONSEQUENCES DIAGRAM ²⁾

A **sequential** graphical **model** that aims at the complete **description** of the antecedents and consequences of some **event**.

This a very practical systemic tool for **risk analysis** and **assessment**, based on preliminary studies of specific cases in some activity, generally industrial. Its use aims at the better **understanding** of what should be or not be done at each moment during the successive **stages** of some critical **situation**.

A. LEROY and J.P. SIGNORET, who describe the **methodology**, based on **binary sequences** of successive alternatives, give an interesting example of its use as applied to some risky incidents in oil extraction at sea. (1992, p. 34-5).

The **methodology** is quite similar to **expert systems**.

0384

CAUTION PRINCIPLE ¹⁴⁾

Innovation of any kind should be carefully scrutinized in order to try to understand their possible **side effects** and, in cases, to avoid them.

Unobtrusive possible effects may include **delayed effects**, **mass effects**, **spillover effects**, etc., all of them easily ignored or underestimated, but frequently quite difficult or impossible to overcome, once manifested. This is specially important in applications of scientific discoveries.

Countless examples have been registered during the 20th Century, as for example acquired resistance of many kinds of bugs to insecticides, and of pathogens to antibiotics, or unmanageable cars traffic in cities and roads.

The first condition for practical caution is the **understanding** of possible **links**, between apparently unconnected aspects, or eventual **accumulation** of effects **short, medium and/or long term**

At least a clearer **understanding** of not obvious effects permits a better balanced **evaluation** of **decisions** to be made, or not.

Caution principle is also known as "precaution principle"

→ **Cassandra's syndrome**; **Risks analysis**; **Risks in human issues**

0385

CELL ²⁾ - 5)

The most basic biological **level of organization** in J.G. MILLER's **taxonomy of living systems**.

Interconnected and interacting cells (1st **level of organization**) form **organs** (2nd **level**).

Cell also means an **element** in so-called "**cellular automata**".

J. HOFFMEYER (1995, p. 23) gives the **cybersemiotics** and **autopoietic interpretation** of the cell: "The simplest entity to possess real genuine **semiotic competence** is the cell. This is because the cell is a **self-referential system** based on redescription in the **digital code** of DNA"

0386

CELL 2 ¹²⁾

Any closed portion of **space**.

An entity with an **enveloppe** which defines an internal **space** and an external one is basically a cell, of whatever kind. Most generally, the **internal space** tends to acquire an **organization** different from the **outer one**.

0387

CELLULAR ARRAY ²⁾

"A subdivision of a limited **space** into units which completely fill the **space**" (1976, p.53).

K. CULIK II & A. LINDENMAYER state: "Tessellations and maps are examples of two-dimensional cellular arrays" (Ibid.). This is somewhat unexpected, since what the authors seem really to have in mind, are **dynamic** cellular arrays. (see following heading).

These authors, being mainly interested in biochemical and cytological aspects, concern themselves "... primarily with **neighborhood** aspects of such arrays, i.e. **topological** aspects, and not with their detailed metric **descriptions**". They thus choosed **graph representation**.

What they proposed is "... a powerful and general **mechanism** for defining **connection rules**, dependent on **node** and **edge labels**, **edge directions**, and on the **structure** of the **neighborhoods**" (p.54).

0388

CELLULAR AUTOMATA ARRAY ²⁾

"... an interconnected collection of similar sub-units ... (each of which is) usually not to be more complex than a finite **automaton**" (p.45).

A. LINDENMAYER and K. CULIK II define this **model** and state some shortcomings of former **models** of the kind: "In the case of the McCULLOCH-PITTS nerve **net models**, the problem is that the **size** of the array remains constant; furthermore, that the entire array behaves as a single finite **automaton**. In the case of von NEUMANN's **self-reproducing automata**, the array is laid out on a square grid and is allowed to grow only at the margins (i.e. the active part of the array). While these **structures** are as powerful as **TURING machines**, they are not suited to simulate in a realistic manner growing cells or multicellular **organisms**" (Ibid).

To remedy these limitations, the authors proposed a **modeling** method whose principle is what they call **parallel rewriting of graphs**.

The formalism they propose seems closely related to the specific problem of **internal growth of networks**, as for example in embryology and more generally in **morphogenetic fields**. The subject is also closely related to the "Physics of vegetal spirals" and **FIBONACCI series** (see St. DOUADY and Y. COUDER - 1993).

0389

CENTRALIZATION ²⁾

"The **process** whereby the **interaction** coefficients increase in a **part** of a system or in an individual **element**" (I.V. BLAUBERG, V.N. SADOVSKY & E.O. YUDIN, 1977, p.55) (Adapted).

BLAUBERG, SADOVSKY and YUDIN conclude: "As a result, small variations of this **part** (the leading **part** of the system) produce essential variations in the whole system" (Ibid).

Poly-centralization and hierarchized centralization appear possible.

0390

CENTRALIZATION (Progressive) ^{1) - 2)}

Emergence of a part of the system, which starts to act as a global center of **regulation** and **control** (According to A.D. HALL & R.E. FAGEN, 1956, p.22).

As the **complexity** of the system increases, the **coordination** between its numerous differentiated **functions** become more necessary and, at the same time, more difficult. This **coordination**, however, takes place automatically by the interplay of countervailing **regulations** at different hierarchical **levels**.

The global center of **coordination** appears at the higher **level** and must in principle take charge only of the most general **problems** which are significant for the system as a **whole**.

It can be said that centralization becomes excessive when the global center of **coordination** starts meddling inefficiently with local or specific **problems**, encroaching on the **regulation** centers activity at lesser **levels**.

0391

CENTRALIZATION versus DECENTRALIZATION ^{1) - 4)}

According to K. BOULDING: "Centralization produces failure to optimize because of the breakdown of the **communication network**. Decentralization on the other hand produces **suboptimization**, from the point of view of the **organization** as a **whole**, and likewise produces a failure to optimize" (1972, p.88).

It becomes clearer that, in well organized systems, some basic **functions** should be centralized and secondary or local ones, be decentralized. The **model of heterarchical organization** should be helpful in this.

0392

CHAIN REACTION ¹⁾

"A reaction that proceeds in a series of steps with each step being made possible by the preceding one" (UNESCO-UNEP, 1983, p.7).

A chain reaction may lead either to a **run-away** in case of unchecked **positive feedback**, or to **dynamic stability** as for example when a **hypercycle** sets in, or still, to the progressive extinction of the **process** in case of damped **oscillations** leading to a final **static equilibrium**.

0393

CHANCE ³⁾

The characteristic of unexpected, unpredicted or **random events**.

The idea of chance is not much more than a mental crutch, corresponding to our lack of understanding of the generally very complex causes of more or less **random events**. With

the discovery - at least partial - of these complex causes through **chaos theory**, the basic nature of what we call chance has become at least somewhat clearer.

0394

CHANGE ¹⁾

The **transition** from one **state** to another in a system, or from one value of some **variable** to another in a **function**.

Change can be **periodic** or aperiodic; **random** or **determined**; swift or slow (according to some **time scale**); local or global, i.e. affecting some **structure and function**, or the system as a **whole**.

It can also be **cyclical** in a simple or complex way. It may remain channeled within **limits**, or escape from them.

The most radical changes, as stated by I. PRIGOGINE, occur when: "**nonequilibrium macroscopic** conditions create new **microscopic processes** which in turn change the **macroscopic** conditions, and so on" (1984, p.61).

Each type of change is related to some specific cybernetic and/or systemic **behavior**.

The **perception** of change depends on the capacities of our senses, possibly aided by **artefacts**; on our specific training and on the **correlation** between our own **time scale** and the **scale** of change. We are ill equipped to perceive very small or very large change, as well as very swift and very slow ones. As a result we are exposed to be surprised by **delayed** or **mass effects** and **catastrophes**.

0395

CHANGE AGENTS ^{1) - 4)}

Changes do not occur without causal agents, which can be of very different types.

It is important to try to recognize such agents when they are still **potential** or in incipient **activity**, because this is the only way not to be caught by surprise, experiencing negative **effects** or missing opportunities.

Apart from their nature, their ways of acting may give us inklings about their possible **timing** and **effects**. Such a **knowledge** is practically the only way to acquire at least a modicum of **predictive** capacity.

It may also lend us some possibilities to adapt to future changes or even to make a creative use of them when they surface.

J.H. MILSUM observed the importance of change in the **stimuli** as: "...in (their) absence most of the relevant **receptors** generally cease to be stimulated" (1968, p.44). He also notes that, in the long run, the lack of change in **stimuli** may lead to the partial or total impairment of specific **perceptions**.

J.A. JOHANNESSEN and A. HAUAN introduce the notion of a change agent as a specific person in an **organization**, who normally introduce changes, whether technical, organizational or conceptual (1992, p.174).

0396

CHANGE (Forms of)^{1) - 2)}

We do not generally pay much attention to the concept of change and as a result, our evaluations of some changes that we witness are frequently erroneous or out of step with reality.

If we consider change in systems and systemic **processes**, we may establish the following tentative **classification** of its different possible modalities.

- Morphostasis	linear periodical or cyclical (or autopoietic-homeostatic)
- Growth	generally homeorhetic , non linear logistic , or within asymptotic limits in systems already autopoietic , but not yet mature
- Morphogenesis	non-linear without limits viz- logarithmic , exponential , factorial leads to discontinuities ("catastrophes")
- Emergence and Evolution	discontinuity leading to higher level of organization

The correct understanding of the kind of change in a **process** or a system is of paramount importance for better **predictability**.

Moreover some specific type of systems or **processes** change generally depends on the **stability** or **instability** of their **meta** (or **supra**) **system** or **environment**.

Some authors (viz. WILDEN, 1972) seem to understand **morphogenetic** change as cyclically **autopoietic**. Others (viz. WADDINGTON) consider **homeorhetic growth** as **morphogenetic**. Contrarywise ROBB considers that "unexpected degrees of freedom appear" which may lead to "**emergence of order at a higher level... or collapse**" (1990, p.140).

The very basic concept of change is now modified by the recent developments of the theory of **Self Organized Criticality**. P. BAK writes: "Any small **change** of any **event** (Note of the editor: or possibly any different small **event** - or in any case simply any **event**, even small) will sooner or later affect **everything** in the system. If the initial **event** caused a large **avalanche**, the **effect** will take place sooner rather than later" (1996, p.159)

0397

CHANGE (Incremental)→ **Change (Rates of)**

0398

CHANGE (Principle of nonproportional)^{1) - 2)}

"It is impossible for **models** of different **sizes** to possess identical characteristics"

The principle has been enunciated by K. BOULDING (1956, p.66-75), who comments: "As any **structure** grows, the proportions of its **parts** and of its significant **variables** cannot remain constant. It is impossible... to reproduce all the characteristics of a **structure** in a **scale model** of different **size**. This is because a uniform increase in the **linear dimensions** of a **structure** will increase all its areas as the square, and its volumes as the cube... As some of the essential **functions** and **variables** of **structure** depend on its **linear dimensions**, some on its areal **dimensions**, and some on its volumetric **dimensions**, it is impossible to keep the same proportions between all the significant **variables** and **functions** as the system grows.

"This principle has two important corollaries. The first is that **growth** of a **structure** always involves a compensatory change in the relative **sizes** of its various **parts** to compensate for the fact that those **functions** and properties which depend on volume tend increasingly to dominate those depending on length. Large **structures** therefore tend to be "longer" and more convoluted than small **structures** in the attempt to increase the proportion of **linear** and areal **dimensions** to volumes" (p.71).

BOULDING gives interesting examples from biology to insect and human architecture.

"The second corollary follows immediately from the first: If the **process** of compensation for structural disproportion has **limits**, as it seems to be the case, the **size** of the **structure** itself is limited by its ultimate inability to compensate for the non-proportional changes. This is the basic principle for the "law of eventually **diminishing returns to scale**" familiar to economists" (p.72).

This corollary shows that the **analogy** between dinosaurs, business conglomerates and bloated bureaucracies is quite more than a **metaphor**. It also shows how much any type of **organization** would benefit from a better understanding of global **isomorphisms**.

BOULDING still adds: "It is interesting to note that the principle of compensation may operate in two very distinct ways - in the direction of attempt to **solve** the **problems** posed by large **scale** or in the direction of an attempt to **avoid** these **problems**" (p.72).

Of course, the second way is generally much more economical than the first one, since the reduction of an overgrown **structure** is much more costly - when still possible! - than the means usable to avoid its excessive **growth**.

0399

CHANGE (Propagation of)¹⁾²⁾

In complex systems, propagation of change is very difficult to evaluate in real time and still more difficult to forecast.

It is in most cases a **percolation phenomenon** as for ex. in floods or in forest fires. This is so because:

- change can be self multiplying in a **fractal** form, for ex. by the production of flying sparks in a forest fire
- some **parts** of the **environment** are more conducive than others to propagation: sparks can trigger a new focus on a dry place or be extinguished in a pool of water

Such types of **propagation** are very difficult to predict because they affect environments which are similar to **non-homogeneous networks**, with locally different characteristics, which may, or may not brake or accelerate the **process** and, in cases, start secondary sequences of **events** of different types.

These in turn can be multiplicative by **positive feedbacks** or self-limitative by negative ones.

0400

CHANGE (Rates of)¹⁾

Every system and **phenomenon** has its own rate of change, which may even change with **time**.

We still lack a good general systemic theory of rates of changes. This is a gap that needs urgently to be closed.

In particular, the non **perception** of slow change is one of the most dangerous problems for **social systems** endowed with the power to change practically every aspect of their internal **organization** and **interrelations** with their **environment**.

Slow changes result in **large scale effects** whose **accumulation** is slow and insidious and whose reversal may be very difficult. The true importance of this matter is now becoming patent in problems of global climate change or loss of genetic **variety**, for example.

0401

CHANGE (Second Order)¹⁾

A change framed within or brought upon the physical or mental **memory** of former **situations**.

With time, any evolving or **learning** system accumulates **structures**, **functions** and/or **memories**, which do not anymore disappear and become the unavoidable **frame** for future **adaptations**, for which they offer short cuts.

G. BATESON emits the following comment: "The very economy of **trial and error** which is achieved by **habit formation** is only possible because **habits** are comparatively "hard pro-

grammed", in the engineers' phrase. The economy consists precisely in *not* re-examining or rediscovering the premises of **habit** every time the **habit** is used" (1973, p.245)

0402

CHANNEL¹⁾

"The instruments (objects, **events**, and their properties) that produce **transmission**" (R. ACKOFF & F. EMERY, 1972, p.190).

"That part of a **communication** system along which **messages** are conveyed, or its mathematical **representation**" (G. PASK, 1961, p.114).

R. ACKOFF and F. EMERY give the following examples: "In sending a letter, the postal service is the channel, in telephone communication it is the telephone system, and in speech it is the atmosphere" (ibid).

There are numerous different types of channels. Some examples are:

- a telephone wire
- electro magnetic waves of well defined **frequency**
- atmosphere as **transmitter** of sounds
- the operating system within a computer
- defined **paths** within the nervous system

To be transmissible through a specific channel, **information** must be translated into the kind of **signals** proper to the channel. This is done by a sender using a **code**.

The physical **code** to be used should not be confused with the **code** expressing **meanings**. Generally, *both* are needed.

A physical channel has a specific capacity to convey so many **signals** per **time-unit**, as a maximum. The main concern of an engineer is the **choice** of the best possible type of channel corresponding to some **class** of **signals** to be transmitted; the protection of this channel against outside **perturbations (noise)** and, if this is not absolutely possible, calculating the number of repetitions of the **signals (redundancy)** needed to maintain intelligibility.

Of course, this complex **process** of **communication** is used to transmit **information**, but this should be understood in a quantitative sense. For example, a channel may be able to carry so many **bits** per second, when in optimal condition, i.e. noiseless. This is however never possible in any real channel. And, taking **noise** into account, the **transmitter** should allow for so many **bits** of **redundancy** per second. It is in this sense that **information** can be quantified.

0403

CHANNEL and NET^{1) - 2)}

"The **subsystem** composed of a single route in physical **space**, or multiple interconnected routes, over which **markers** bearing **information** are transmitted to all parts of the system" (J. MILLER, 1978, p.3).

This is one of the 20 critical **subsystems** in MILLER's **taxonomy of living systems**. As such, it offers general characteristics for channels and nets and is submitted to the general limitations of the same.

Channel and net appear in a similar way in FORRESTER's **Systems dynamics**.

0404

CHANNEL CAPACITY²⁾

The maximum **rate** (expressed as the number of **information** units per second) at which a channel can transmit **messages** with minimal distortion.

According to C. SHANNON: "If the **source** is of a simple type, releasing **symbols** of equal length (as in the case of a teletype for example), if in this **source** each chosen **symbol represents s information bits** (freely chosen from 2ⁿ **symbols**) and finally the channel may transmit, let us say, n **symbols** per second, the capacity C of the channel is then defined as being ns **bits** per second" (1949).

This is of course a strictly quantitative and numerical **measurement**, once the needed **energy** has been used to create the **signals**. In R.N. ADAMS words: "The channel capacity of a telephone **circuit** refers to the fact that the physical composition of the **circuit** can receive only a finite amount of energetic **activity** over a given **period of time**" (1988, p.84).

0405

CHANNELS (Cost of)¹⁾

Channels for any kind of **communications** must be constructed and maintained. H. ODUM states: "The many channels required to make the special chemical and physical **structures** for maintaining ordered **networks** take much work and therefore much **metabolic energy**" (1971, p.98).

This is also true for non-biological systems, as may be observed in any human **organization**.

0406

CHAOS^{1) - 2) - 3)}

"The irregular, unpredictable **behavior** of **deterministic nonlinear** systems (R. JENSEN - 1987, p.168).

"The operation **mode** of persistently unstable systems" (after B. JONES, 1994).

This **meaning** of the term "chaos" was introduced by J. YORKE, of Maryland University (1975).

It is not possible to develop, even sketchily, the concept of chaos in this dictionary, basically because:

- 1) it is highly complex with broad mathematical development
- 2) it is still in the making

According to A.B. CAMBEL, chaos theory is "a heterogeneous amalgam of different techniques of mathematics and science. Systems that upon analysis are found to be **nonlinear**, **nonequilibrium**, **deterministic**, **dynamic** and that incorporate **randomness** so that they are sensitive to **initial conditions**, and have strange **attractors** are said to be chaotic" (1993).

J. GLEICK introduces chaos in the following terms: "To some physicists chaos is a science of **process** rather than **state**, of becoming rather than being...

"Chaos breaks across the lines that separate scientific disciplines. Because it is a science of the global nature of systems, it has brought together thinkers from fields that had been widely separated...

"Chaos poses problems that defy accepted ways of working in science. It makes strong claims about the universal **behavior** of **complexity** (1987, p.5).

As to its real importance, GLEICK comments on R. MAY opinion: "Chaos should be taught, he argued. It was time to recognize that the standard education of a scientist gave the wrong impression. No matter how elaborate **linear** mathematics could get, with its **Fourier transforms**, its orthogonal functions, its regression techniques, MAY argued that it inevitably misled scientists about their overwhelmingly **nonlinear** world: "The mathematical intuition so developed ill equips the student to confront the bizarre **behavior** exhibited by the simplest of discrete **nonlinear** systems" he wrote.

"Not only in research, but also in the everyday world of politics and economics, we would all be better off if more people realized that simple **nonlinear** systems do not necessarily possess simple dynamical properties" (p.80).

The chaos **concept** is an important part of a new **set** of mathematical theories at present in process of build-up. It is more or less closely related to **catastrophe theory**, **stability** theory, **fractals**, a renewal of the **concept** of **cycle**, general **topology**, **thermodynamics of irreversible systems far away from equilibrium** and **criticality** and **percolation theory**.

It has led to a deep questioning of the traditional - and absolute - notions of **determinism** and **randomness**. Formerly, in the words of GLEICK: "Either **deterministic** mathematics produced **steady behavior**, or **random** external **noise** produced **random behavior**. That was the choice.

"In the **context** of this debate, chaos brought an astonishing message: simple **deterministic models** could produce what looked like **random behavior**. The **behavior** actually had an exquisite fine **structure**, yet any piece of it seemed indistinguishable from **noise**" (p.78-9).

Also J. CASTI emphasizes: "Scientifically speaking, chaos is only the appearance of **randomness**, not the real thing" (1994, p.88).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

I. EKELAND, in turn, cites MAXWELL: "It is a metaphysical doctrine that the same antecedents always produce the same consequents. Nobody could deny it. But it is of reduced usefulness in a world like this one, where the same antecedents can never be found and where nothing recurs twice... The physical axiom which looks alike is that similar antecedents produce similar consequents. But here we changed from exactness to **similarity**, from absolute precision to a more or less crude approximation" (1984, p.85).

Chaos definitely puts an end to LAPLACE's Clockwork Universe and, altogether, to the age old dream of absolute **predictability**.

In any **complex system**, and at any moment, there is a new set of **initial conditions**. This leads to the practical impossibility of definite evolutive **forecasts**, as possibilities relentlessly open up at any future **time** and the internal **correlations** of the system become reduced. The only **invariance** is a global **enveloppe embedding** many possibilities as no future **transformations** can escape the historical development of **archetypes**.

From another viewpoint, as stated by Chr. VIDAL: "...the **strange attractor concept**, while undoubtedly broadening the recognized domain of **determinism**, simultaneously establishes on quite more strong bases the need to resort to statistical methods... now imposed by the very logic of mathematics" (P. BERGÉ et al., 1984, p.288).

It should at last be recognized that "pure" **determinism**, as well as "pure" **randomness** are merely ideal limit cases of all possible **behaviors** of systems, corresponding, the first to strictly **lineal** systems and the second to completely degraded **order**.

As observed by E. LASZLO: "Chaos is not the opposite of **order** but its refinement: it is a subtle, complex, and ultrasensitive form or **order**" (1992, p.243).

This is probably the reason why science started to discover it just one century ago (POINCARÉ's **three bodies problem**) and to explain it no more than 30 years ago (E. LORENZ).

0407

CHAOS (Anti-) ¹⁾

A property of "some very disordered systems (which) spontaneously *crystallize* into a high degree of **order**".

Such "very disordered systems" seem to contain implicate **order**, through the **nonlinear interactions** between a number of different **simultaneous** types of **behavior** within the system. These result in a very complex global **determinism** at such a very **long term time horizon** that it either cannot be observed, or becomes deeply transformed in **time** by **perturbations**. See "Prime numbers" and "Three Bodies Problem".

"However, in some cases, these **nonlinear interactions** become associated in such a way as to generate a strongly unifying and self-maintaining **pattern**. **Solitons** are good examples of this kind of **self-organization**.

According to J. BRIGGS & F. DAVID PEAT (1989), **solitons**, very far to be only a rare and curious hydrodynamic **phenomenon**, as for example giant waves that sometimes appear in oceans, would be a very general one, even in biological systems and in nervous transmission.

0408

CHAOS (Centre for Hyperincursion and Anticipation in Ordered System) ¹⁾

This Centre, based at the Institute of Mathematics, University of Liège, Belgium, is focusing its activity on **anticipatory processes** and systems, in a **transdisciplinary** spirit.

Its founder and mentor, Prof. Daniel Dubois, writes: "Anticipation is not only a property of biosystems, but is also a fundamental property of physical systems. In electromagnetism, the **anticipation** is related to the Lorenz transform. In this framework, the anticipation is a strong anticipation because it is not based on a prediction from a **model** of the physical system, but is embedded in the fundamental system".

In fact, the proceedings of the yearly meetings of the CHAOS Centre (organized since 1997) show a widely embracing **transdisciplinary** viewpoint. Published papers include not only general concepts and **models**, but also anticipatory studies related to biological systems, psychology, psychiatry, **linguistics**, economics and **social systems**.

Papers also consider modelling means as **neural networks**, **genetic algorithms**, **automata**, **holograms**, **fractals**, etc.

The Centre publishes its "CASYS- International Journal of computing Anticipatory Systems"

More information can be obtained at the page: <http://www.ulg.ac.be/mathgen/CHAOS/CHAOS.html>

0409

CHAOS (Computability of) ⁵⁾

According to R. JENSEN: "Another manifestation of the **unpredictability** of **chaotic dynamical systems** is that the time-evolution is computationally irreducible. There is no faster way of finding how a **chaotic system** will evolve than to watch its **evolution**. The **dynamical system** itself is its own computer" (1987, p.179).

However, we can nevertheless compute reliable odds or probabilities for the outcome of these **processes** (i.e. for example football, or soccer games or turbulent flows). As a conse-

quence probabilistic and statistical theories provide a natural **description** of average properties of **chaotic systems**".

"... Since simple **models** can yield complex, irregular **behavior**, we can actually hope to develop theoretical **descriptions** of a wide variety of apparently **random**, unpredictable natural **phenomena** using mathematical **models** which exhibit deterministic **chaos**" (Ibid).

Hence, the paradoxical situation appears wherein **determinism** can be partly described from a **random** base, but never in a such precise way as to allow for rigorous **prediction**.

0410

CHAOS (Control of) ^{1) - 2)}

E. OTT and M. SPANO showed that, while "the extreme **sensitivity** and complex **behavior** that characterize **chaotic systems** prohibit long-range **prediction** of their **behavior**", they "paradoxically allow one to **control** them with tiny **perturbations**" (1995, p.34).

They explain this **stabilization process** as follows: "The **periodic** orbits embedded in a **chaotic attractor** are all unstable in that if one displaces the system **state** slightly from a **periodic** orbit, this displacement grows exponentially with **time**. Thus **periodic** orbits are typically not observed in a free running **chaotic system**". However: "Very infrequently a **chaotic** orbit may, in its **ergodic** wandering, approach close to a given **periodic** orbit. If this happens, the orbit may approximately follow the **periodic** orbit for a few **cycles**, but subsequently moves away, resuming its wandering over the **chaotic attractor**".

The **control** problem consists in stabilizing these "wanderings" near some selected **periodic** orbits. To do this the authors state: "We tailor our small **time-dependent controls** in such a way as to stabilize one of the **unstable periodic** orbits that yields improved **performance**" (p.35-6).

In this way, the **ergodic** character of the system could be to some extent reduced. (For technical details see this very suggestive paper).

The experimental research, to date, shows the feasibility of chaos control. The authors conclude: "The remaining question is whether it will prove possible to move from laboratory demonstrations on **model systems** to the real-world **situations** of economics, engineering and societal importance. The ubiquity of **chaotic dynamics** leads us to suspect that this will indeed be the case" (p.40).

The other remaining question is however if meddling with **naturally chaotic systems** would necessarily be wise. The **rhythm** of the heart pulses for example has been proven to be normally slightly **chaotic**, possibly as this implies **adaptive variety** to internal and external **disturbances**. We are in problems when this **rhythm** becomes too narrowly and regularly

periodic. We should beware not let ourselves entrapped in our classical **semantics**, according to which **chaos** is "bad" or "scandalous" in itself.

→ **Chaotic system (Stabilization of a)**

0411

CHAOS (Deterministic) ^{1) - 2)}

Unpredictability in a globally deterministic system.

Systems affected by deterministic chaos are **nonlinear** and have a high **sensitivity to initial conditions**.

Generally speaking, **predictability** is (more or less) possible at global **level** and impossible at local ones.

It also swiftly diminish into the future. However "... recent developments in **self-organization models** and **nonlinear thermodynamics** have attracted attention to the opposite **phenomenon**: microscopically **deterministic** systems that behave in a completely **unpredictable** way when considered from a macroscopic viewpoint. Examples are the so-called "deterministic chaos" and certain types of **cellular automata** whose local dynamical **rules** are completely **deterministic** but for which there is no global **algorithm** allowing to predict their overall **evolution** without computing all the individual, microscopic **transitions** from the given **initial state**". (F. HEYLIGHEN, 1989, p. 378; also S. WOLFRAM, 1984).

However, these systems are only globally (but not "completely") **unpredictable**: they would have a global **vicinity of behavior**, at least until a **bifurcation** makes them cross a **stability threshold**, changing their nature by **emergence**, or destroying them.

According to P. DAVIES: "...the study of chaos has revealed how it is possible to reconcile the **complexity** of a physical world displaying haphazard and capricious **behaviour** with the **order** and simplicity of underlying laws of nature" (1990, p.51).

However: "The key feature of a chaotic **process** concerns the way that predictive **errors** evolve with **time**" (ibid., p.49), i. e. the way they rapidly increase and practically destroy **predictability**".

0412

CHAOS (Edge of) ²⁾

A **threshold** zone of complex **dynamics** unstably balanced between determined **order** and chaos.

R. LEWIN, in his review of St. KAUFFMAN's book "The Origines of Order" explains: "This poised state... offers rich possibilities for computation in mathematical **models**. KAUFFMAN draws on these principles and develop rich im-

ages and cogent mathematical **descriptions** how they might operate within biological systems. Life, he suggests, exists on the edge of chaos" (1993, p.46).

Emergence of higher **levels of organization** seems possible in dynamical **situations** freed from rigid **order** of controlled **stability** where **behavior** may become "most flexible, complex and adaptable" (ibid).

0413

CHAOS (Free will and) ^{1) - 3)}

J. CRUTCHFIELD et al. state: "Innate **creativity** may have an underlying chaotic **process** that selectively amplifies small **fluctuations** and molds them into macroscopic mental states that are experienced as thoughts. In some cases the thoughts may be **decisions** or what are perceived to be the exercise of will. In this light, chaos provides a mechanism that allows for free will within a world governed by **deterministic laws**" (1989, p.49).

This hypothesis could be well grounded if the **brain's neuronal nets** are the seat of **chaotic processes**. (This subject would justify a thorough investigation). It would be the case if various interconnected **subnets** should simultaneously show independent **periodic oscillations** whose **frequencies** would not have a common divisor.

As to "**deterministic laws**" it is now obvious that the **meaning** of the word "**deterministic**" direly needs a careful revision, precisely in the case of chaotic **behavior** in **complex systems**: **determinism** is not abolished, but it becomes relativized in a way which is not yet quite clear.

0414

CHAOS: Historical meaning ¹⁾

Originally a greek word meaning chasm, abyss. This derived toward meanings like undifferentiated, confused, disordered, shapeless.

E. SCHWARZ, in his "Systemic Glossary" (in french) states "Chaos: Initial unorganized state of the world in Hesiod's cosmogony (8th b.C.) in which is it nevertheless possible to recognize the primeval dyad Gaia and Ouranos, as well as the primeval Eros, the dynamical principle" (1993, p. 2)

Curiously this type of chaos never went away from human minds. Its more recent expressions are the Big Bang and its first moment "inflation", or the recent resurgence of the aether as the locus of materialization of paired particles (positive and negative) out of ...a "something-nothing"

→ **Entelechy**

0415

CHAOS (Onset of) ²⁾

P. BERGÉ and M. DUBOIS describe three different ways leading form a **periodic behavior** to a chaotic one:

- By **period doubling**, where the basic **period** is multiplied by 2 at each **bifurcation**, until an infinite **period** is approached;
- The **intermittences** scenario, in which the **periodic states** become slowly disorganized until suddenly exploding into **turbulence**;
- The quasi-**periodicity** scenario wherein the **nonlinear interactions** of 2 or 3 **oscillators** lead to **chaotic behavior**. (1992, p. 128).

→ **Ergodicity**

0416

CHAOS (Weak) ^{1) - 2)}

Characteristic of a **composite system** which "evolves on the border of chaos" (P. BAK & K. CHEN, 1991, p.32)

These authors state: "This **behavior**... is a result of **self-organized criticality**. Weak chaos differs significantly from fully **chaotic behavior**. Fully **chaotic systems** are characterized by a **time scale** beyond which it is impossible to make **predictions**. Weakly chaotic systems lack such a **time scale** and so allow **long term predictions**" (p.32).

This seems somehow debatable. From one part so-called "full chaos" seems to maintain for extremely long periods a measure of global **determinism**. On the other hand, even on base of a known **flicker noise** some **uncertainty** (growing with **time**) always remains as to when a **runaway event** or **percolation process** may appear. It must be conceded however that a stock market or a **population crash** is creating the conditions that impede another stock market crash or population crash. The **percolation event** destroys the global **cluster** that it has built... but leaves open the possibility of reconstruction of another **cluster**.

Compare with "**ergodicity**"

0417

CHAOTIC DYNAMICS

→ **Dynamics (Chaotic)**

0418

CHAOTIC SYSTEM ¹⁾

J. BRIGGS and F.D. PEAT state: "Chaotic systems are locally unpredictable, but globally stable" (1991, p. 74). They give the now classical example of climate.

According to K.B.DE GREENE (1990, p.52), who quotes R.L. DEVANEY (1987): "... a completely chaotic system (is) one that is **unpredictable** (highly dependent on **initial conditions** that greatly reduce the accuracy of numerical study), indecomposable (the system cannot be broken into **subsystems**), and recurrent (producing **periodic orbit**). These features correspond to physical systems that show **turbulence**"

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

And: "... systems (may) not be completely chaotic and may show limited windows of chaos. In systems **evolution** chaos and **turbulence** may well be prerequisite to **structural change**".

These concepts are also applicable to **eco-systems** and **sociosystems**.

→ **System (Ergodic)**

0419

CHAOTIC SYSTEM (Stabilization of a)²⁾

According to Ed. OTT et al. (1990, p.1196), as quoted by D. BROOMHEAD, a chaotic system can be stabilized, at least in the absence of other uncontrolled effects as for example genuine **noise** "... by repeated application of small **perturbations**, in a **state** which approximates the chosen **state** to within a preset **error**. By keeping the **error** small, the magnitude of the **perturbation** is correspondingly kept below a **threshold p****" (1990, p.23).

However, this is possible only "... when the chaotic wandering has brought the system sufficiently close to the center C (of the **saddle** of the **attractor**). It is property of the **chaotic attractor** that this will happen after an unknown but finite **time t**" (Ibid.).

→ **Chaos (Control of)**

0420

CHEMOTAXIS⁵⁾

"A **phenomenon** whereby a chemical released in the system attracts or repels a **population of cells or organisms**" (I. PRIGOGINE, P.M. ALLEN and R. HERMAN, 1978, p.40).

Chemotaxis is a **socialization** factor, in the same class as pheromones in social insects. It induces a kind of spatial **anisotropy**, as for example in the amoeba *Dictyostelium discoideum*, whose **aggregation** is controlled by the **level** of adenosine triphosphate (AMP) secreted by the **cells**. It is also operating in the construction of the nervous system, as shown by the recent discovery of so-called netrin proteins, which guide the growth of axons, by a team under the lead of M. TESSIER-LAVIGNE (Scientific American, Jan. 1995). The establishment of this type of spatial **gradient** is quite a general **phenomenon**. It corresponds probably to some not yet discovered similar one in human crowds showing collective nonrational **behavior**, yet to be explained.

0421

CHESS AS A DESTRUCTIVE DYNAMIC GAME^{2) - 5)}

A. LOTKA stated as early as 1924 the basic characteristics of chess as a systemic **game** and described them as follows:

"The elements that determine the course of the **game** are as follows:

1. A topographic map, a chart of geometric **constraints**, the chess board.

2. Movable upon this chart, a number of movable points (chessmen), each the **center** of a **field of influence**, defined for each movable point in relation to the geometric **constraints**. So, for example, the field of influence of a pawn extends to the two squares diagonally in front of the pawn.

3. A law restricting the **time-rate** of advance of each moving point (moves alternate from white to black).

4. A law defining the influence upon each other of two points in **collision**, i.e., two points whose fields of influence have interpenetrated to a prescribed extent. An example of this is the **rule** that a chessman arriving upon a square occupied by a hostile piece, throws the latter off the board.

5. A law restricting the movements of the points when not in collision, i.e., when outside one another's field of influence. So, for example, a bishop may move only diagonally.

6. The elements enumerated so far place **restrictions** upon permissible changes (moves). These elements alone cannot, evidently, **determine** any occurrence of any kind. Absolute immobility, for example, or any **random** move that did not violate the **rules** of the **game**, would equally satisfy the conditions enumerated.

7. In addition to the elements 1,2,3,4,5, there must therefore be in operation some positive principle (tropism) which not merely restricts possible occurrences, but which determines actual **events**. In chess this principle is furnished by the effort of each player to bring about checkmate" (1956, p.343).

A similar analysis could be made of the **game** of GO or the **games of life** of J. CONWAY. **Similar rules** were also proposed by M. MARYAMA in his **2nd Cybernetics**.

All these **games** could be very useful for the study of the **transformations** of numerous natural and artificial systems based on different **rules**... and for aiding man to become a better chess player on the planet's chessboard!

0422

CHINA IN SYSTEMS SCIENCE¹⁾

The Chinese Institute of Systems Sciences is established in Beijing.

Under the leadership of Prof. GU JIFA and in collaboration with the Centre for Systems Studies at the University of Hull (UK) a first International Conference was organized in Beijing in 1995. The conference was supported by the National Science foundation of China.

Scholars from China, Japan and the United Kingdom took part in the event and the Proceedings have been published at the University of Hull under the editorship of Gerald MIDGLEY and Jennifer WILBY.

This event signaled in fact the effective entry of the Chinese systemists in the international systems community.

In August 2002 the forty sixth Meeting of the ISSS took place at the Tong Ji University Business School in Shanghai, again in connection with the Univ. of Hull Business School. Prof. Mike Jackson, President of the IFSR and Professor at Hull and Dr. ZHICHANG ZHU were Programme Organizers co-chairmen

0423

CHINA-JAPAN-UK. Systems Project¹⁾

A group of systems researchers from China (JIFA GU and ZHICHANG ZHU), Japan (YOSHITERU NAKAMORI) and the UK (M. JACKSON and other Hull University scholars) initiated this cross-cultural learning and integration systems project in 1993-94.

From 1995 to 2001, five project conferences and workshops have been held in China, Japan and the UK., and cross-visits organized.

A detailed report about respective approaches, methodologies and application areas and specific projects has been published in "Systems Research and Behavioral Science", vol. 19 (1), 2002

0424

CHINESE SYSTEMS CONCEPTS AND METHODOLOGIES¹⁾

The authors describe as follows the concepts in Chinese thinking that form the basis of a Chinese systems methodology: "The basic theme of Wuli, Shili and Renli contends that *wuli* (regularities in objective existence), *shili* (ways of seeing and doing) and *renli* (patterns underlying human relations) constitute a differentiated whole that conditions systems projects. WSR suggests that we should design and employ appropriate methods to address and tackle *wuli*, *shili* and *renli* elements in a theoretically informed and systemic way" (2000, p. 11)

"Such relational philosophies also suggest that the Tao (**morality**), Zhi (**knowledge**) and Xing (**action**) of human beings are systemically conditioning and supporting one another and, therefore, cannot be "artificially" isolated from one another" (Ibid, p. 12)

There is of course much more to it and the subject deserves close attention from systemists in general.

The whole of first issue of volume 13 of SPAR is dedicated to Chinese systems concepts.

→ **China in systems science; Wuli; Shili; Renli**

0425

CHIRALITY^{2) - 5)}

The complementarity but opposed **symmetry** of forms.

The term, derived from the greek language, alludes to the opposed **symmetry** of the hands ("Kheir" = hand in Greek)

An example are levogyre and dextrogyre tartaric acid crystals, an opposed **symmetry** discovered by PASTEUR. Chirality is also very common in **living systems**. It seems to be a quite basic natural feature, somehow related to **symmetry-breaking**.

→ **Enantiomers**

0426

CHLADNI FIGURES ²⁾ - 5)

Patterns obtained by spontaneous ordering of powder or sand on a metallic vibrating plate.

The powder gathers at the nodal lines and materializes the **distribution** of the **energy** induced on the plate by the source of vibrations. Many different **patterns** can be obtained according to the type of powder used.

A historical antecedent was DESCARTES' magnetic phantom. C. LAVILLE also mentions GUEBHARD experiences showing the possibility to materialize KIRCHOFF's diagrams of equipotential lines of forces in a **field** through electrolytic deposition. Many different figures can be obtained. It is surely not a coincidence if many of these diagrams show **structures** quite similar with natural **forms** in **living systems** (For example butterfly wings, bone **structures**, protozoaria, etc...), and also very fundamental **processes** as in the egg's progressive division in embryology. Structural engineering as for example in bridges materializes the same types of **forms**.

For many stimulating developments related to the close relations between **energy flows**, **processes** and **structures**, see d'ARCY W. THOMPSON (1916; 1952) and C. LAVILLE (1950).

0427

CHOICE ¹⁾

The possibility of **selection** between two or more future possible **situations**, or **programs** of **action**.

The **concept** of choice is controversial because it implies at least a partial relativization of **determinism**.

According to P. VENDRYES, only regulated systems with available **reserves** and specified **goals** have such **selection** possibilities at any moment.

Choice is thus not merely a result of **indeterminacy** "à la HEISENBERG". Its relation with **chaotic determinism** and eventual **control** of the same should be explored.

(see D. BROOMHEAD - Physics World 1992)

0428

CHOICE as a systemic topic ¹⁾ - 4)

From the systemic viewpoint, choice is a very complex topic.

According to R.L. ACKOFF and F. EMERY, in a **situation** of choice a **subject** has to decide between various (or at least two) possible courses of **action**, affected with different probabilities (1972, p.146).

As a rational election among options, it thus supposes a good understanding of the nature, the needs and the **situation** of the system which is to make a choice.

However, what is understood as rationality refers solely to the logical aspect of choice, while a systemist must also take in account psychological, social and cultural aspects in their most ample sense. In G. VICKERS words: "... choice involves **valuing**, and **valuing** is by implication excluded from the rational **process**. No calculus can compare the relative values of atom bombs and medicare" (1957, p.64).

He could have added that, even if such a calculus could be made in economic or financial terms, for instance, such a problem is never put in that kind of mental **frame**.

In particular, collective choice is a matter of cultural **consensus**, in most cases neither logical or economic.

For the systemist, the problem of choice is thus multi-dimensional.

0429

CHOICE (Random) ²⁾

An arbitrary **selection** among a number of possibilities.

When some new **design**, or device or **behavior** is to be established and there is no obvious advantage of one type in relation to others, the choice is in some cases arbitrary, i.e. more or less left to **chance**.

Historical examples are right hand traffic in some countries and left hand one in others; or the use of the qwerty or the azerty keyboard in different countries.

However, once the **decision** has been taken, it starts to act as a **constraint**, orienting techniques and behavior in an ever more **deterministic** way. This is because any different way to construct devices or to organize behavior would provoke costly incoherences, squandering of **resources**, losses and finally disruptive **conflicts**. This **process** can only be modified or suppressed through a very deep innovation and, in many cases, a stressful **behavioral adaptation**.

In economy, it has been described as "**path dependence**" (B. ARTHUR, 1994)

This is the specifically technical or behavioral aspect of a much more general random choice **process** described by E. ODUM.

0430

CHOROPLETH ⁵⁾

A line of uniform value in a graphical **representation**. (M. CHISHOLM, 1975, p.62).

Choropleths are used to coordinate series of **observations**, corresponding to some specified areas, for example **population density**, or land-use proportions. They allow for the characterization of areas and comparisons between various ones in which different conditions can be summarized, i.e. allow for the **emergence** of a global meaning for collections of specific **data**.

→ **Hexagonal spacefilling**

0431

CHREOD ²⁾

"A canalised pathway of **change**" (C. WADDINGTON, 1977, p.140) or...

"A canalized **trajectory** which acts as an **attractor** for nearby **trajectories**" (WADDINGTON, 1975, p.22).

C. WADDINGTON explains: "... the name chreod, a word derived from Greek, ... means 'necessary path'".

"I have coined the word "chreod" for what is really a characteristic of an **attractor** surface in a multidimensional **space**" (1976, p.245).

He also states: "Different canalised pathways or chreods may have rather different types of **stability** built into them. These can be pictured in terms of the cross-section of a valley. You may for instance, have a valley with a very narrow chasm running along the bottom, while the farther up the hillside you go, the less steep the slope; with such a **configuration** of the **attractor** surface, it needs a very strong push to divert a stream away from the bottom of the chasm... If the system is acted on by only minor **disturbances**, it is likely always to stay very close to the bottom of the valley" (1977, p.140).

This type of **situation** corresponds to **dynamic stability**.

"In contrast, (if) we have a valley which has a very flat bottom... then, minor **disturbances** can easily shunt the stream from one side of the flat valley bottom to the other" (ibid).

This is still **dynamic stability**, but with more potential **fluctuations amplitude**.

In case of very strong **disturbances**, the system may escape from the chreod, in which case **instability** sets in and the system crosses over into another **domain of attraction** (or **stability**), or undergoes **dissipative structuration**, which will transform its very nature, or still, is destroyed.

It is interesting to note that normal **growth processes** in systems are chreodic, which is well in accordance with their **organizational closure**.

0432

CHREOD (Archetypal) ¹⁾ - 2) - 4)

An hypothetical organizing **pattern** that insures the conservation of the basic characters already acquired through **evolution**.

Ch. SMITH resumes this concept, also due to C. WADDINGTON (1975) as follows: "WADDINGTON... proposes that a similar **deep structure**, one that remains intact even during a complete mutation, must be present in living **organisms** to insure that **evolution** rather than devolution, comes about during mutation **processes**. He argues that mutations frequently involve a breaking down of an **order** that **organisms** have been building up through **adaptive processes**. Given that this breaking-down of **order** does occur during mutation, and most species go through mutations (especially in the development of their life supporting **sub-systems**), WADDINGTON argues that the present **states** of development and **order** found in **living systems** would be highly improbable without some other factor coming into play. He argues that some mechanism must be present to insure that mutation does not **reverse evolution**, destroying the degree of sophistication that the system has previously attained. He call this organizing **pattern** an *archetypal chreod* (WADDINGTON, 1975, p.200), seeing it as similar to a **function** or a blueprint. The *archetypal chreod* provides the mutating **organism** with a line of development consonant with its state of accumulated, evolutionary **learning**" (1986, p.208).

This concept seems to be valid for pre-biotic systems, as well as for **social** and even **abstract systems**. C. BRESCH studies this same mechanism in his book about general **evolution** (from pre-biotic to human) and states that a general **catalytic effect** is at work at least from the atomic level on: "**Structures** influence directly the shaping of new **structures**. This potential influence, that amplifies constantly, will lead us all along in this study". (1977, as retranslated from the spanish traslation).

The concept is also clearly related to the **stigmergy** one and there are probably *archetypal chreods* at work when new societies are born as well as new **languages** or even new mathematical concepts.

0433

CHRISTMAS TREE EFFECT¹⁾

The confusing effect on **perception** of numerous and simultaneous **stimuli**, specially visual.

This effect is fast becoming a very serious **risk** factor in control rooms (industrial, nuclear, etc...) or in front of complex panels of instruments as in an aircraft.

The main causes of the Christmas tree effect are:

- The growing **complexity** of **machines** whose totality is now very difficult to grasp by an **operator**
- The swiftness of technology **evolution** which does not allow anymore for sufficient re-adaptive **learning** and imprinting time

- The passage from a concrete **man machine system** interaction to an abstract interaction in terms of massive symbolic **representation**.

In other words, man seems to come closer and closer to the **limits** of his capacity of **perception**, at least in real time, in front of his own **artifacts**.

0434

CHRONOCENTRISM¹⁾³⁾

A tendency to explain **facts** of the past in terms of contemporary **beliefs**.

The archeologist Timothy TAYLOR gives a typical example: As "many archeologists see...a widespread signature of cannibalism across different continents, in different frames, another group of archeologists start to say: "Well, there must be other explanations- because humans don't do this" (Interview New Scientist, sept.28, 2002, p. 48)

While "**anthropocentrism**" and "**culturocentrism**" are well recognized as a source of dubious **interpretations** in human sciences, there is scant perception of the psychological and socio-cultural differences in former societies. A good example is our deeply seated uneasiness about witch hunting in western societies, a **behavior** that was considered normal to our forefathers, of which some may even have been witch hunters...or "witches."

0435

CHRONOTOPE²⁾³⁾

The **space-time framework** of natural systems.

This neologism is stated by Rafael RODRIGUEZ DELGADO in his last work (1997, p.38). He uses the **concept** in social sciences as well as in physical ones, as a way to avoid a partialized view of, mainly, **human social systems** in their historical **dimension** (p.40).

0436

CHRYZODES²⁾

Geometrical representations of numbers and their arithmetic relations.

Chryzodes have been introduced by J.P. SONNTAG (1994, p. 373-378). Chryzodes are graphical **mappings** in two dimensions of series of numbers obtained by arithmetic operations (addition, subtraction, multiplication, etc.)

The mapping is done within a graduated circle and produces what the author calls a "**cybernetic of forms**". A very high level of **complexity** emerges in the figures.

SONNTAG observes that chryzodes are not **fractals**. Their deeper **meaning** and possible uses remain unclear, but they are curious and attractive.

0437

CHUNKING²⁾

The subdivision of a system into significant fragments.

As **subsystems** possess by themselves a **structural** and **functional** specific value, a system should not be arbitrarily "chunked", as expressed by H. SIMON (1974).

K. KRIPPENDORFF gives an interesting example of **information** chunking in telephone numbers, where specific "prefixes" like 54, or 54.214 are given a specific **meaning** allowing for a significant geographic ordering of telephone numbers, wordly and within a given country (1986, p.11).

0438

CINDYNICS⁵⁾

A discipline that studies the laws of danger (from the greek "kindunos": danger)

Most of the dangerous situations do show the following characteristics:

- they correspond to **transformations** in **complex systems**;
- these **transformations** are frequently quite sudden;
- they are very generally unexpected by witnesses, protagonists or victims;
- they cannot be forecasted by simple **linear** extrapolations.

The laws of cindynics should be investigated in close connection with systemic and cybernetic **concepts**, most specially those about:

- **non-linear growth** and **positive feedbacks**
 - discontinuities (or "**catastrophes**")
 - **dissipative structuration**
 - **instability thresholds**
 - **limits to forecasting**.
- "**Disasters**"; Failure tree; Lusser theorem; Petri net; Reliability

0439

CIRCADIAN RHYTHM⁵⁾

Any **periodic behavior** in **living systems** synchronized with the alternance of day and night.

Circadian rhythms are of cardinal importance for all **living systems**, specially human systems up to the highest societal **level**. Recent research by J.S. TAKAHASHI and M. HOFFMAN (1995, p.158-65) pinpointed J. MILLER's **timer subsystem**, which is ultimately located in the suprachiasmatic nucleus (SNC) in mammalian brains. The SNC is apparently heir to the pineal eye of reptiles. It acts as a "master circadian clock" that commands **time-connected activities** and seems to be ultimately under the **control** of a specific gene, or group of genes, since the **activity** rhythms of mice has been altered by induced genetic mutations.

It is moreover interesting to observe that any animal possesses **organizationally closed** devices at the physiological **level**, responding in precisely specific ways to **environmental stimuli**. The case of vegetals, not yet much researched until now, seems to be similar.

0440

CIRCUIT (Causal)^{1) - 2)}

A circuit which "will generate a **non-random response** to a **random event**" (G. BATESON, 1973, p.380).

BATESON emphasizes that this will happen "at that position in the circuit at which the **random event** occurred" ... and adds: "This is the general requisite for the creation of **cybernetic** restraint in any variable at any given position". (Ibid)

ASHBY's concept of **constraint** is obviously synonym of BATESON's one of restraint.

The causal circuit as a **cybernetic** device "will be activated by changes in **rate** and..., when activated, will operate upon some **variable** ... in such a way as to diminish the change in **rate**" (Ibid).

The notion of causal circuit introduces necessarily the system's view and, moreover, the dynamic dimension of systems.

W.R. WINBURN puts it as follows: "(logical dilemma, like the Epimenides **paradox**) arise from the inability of logic to consider **time** in the **description** of a **causal process**. When **time** is not considered, the ability of a circuit to issue opposite **responses** to identical **stimuli** presents a contradiction. The difference between the **description** of a **linear causal process** independent of **time** and a **description** of a causal circuit in which **time** matters is analogous to a difference of **logical type**. The **time-dependent behavior** of circuits forces us to abandon the **level** of individual **parts** and see instead a "system" that responds as a **whole**" (1991, 559).

0441

CIRCUIT (Closed)^{1) - 2)}

A **loop** in which "... causal interconnection can be traced around... and back through whatever position was (arbitrarily) chosen as the starting point of the **description**" (G. BATESON, 1973, p.380).

BATESON adds: "In such a circuit, evidently, **events** at any position in the circuit may be expected to have **effect** at *all* positions on the circuit at later **times**. Such systems are always *open*: a) in the sense that the circuit is energized from some external **source** and loses **energy** usually in the form of heat to the outside; and b) in the sense that **events** within the circuit may be influenced from the outside or may influence outside **events**" (Ibid).

0442

CIRCUITS (Degenerative - Regenerative)^{1) - 2)}

A circuit may be either degenerative or regenerative, according to the type of **feedback** it includes.

A regenerative circuit, i. e. one including a **positive feedback** (as stated by G. BATESON): "... (will) if provided with the necessary **energy sources** and if external factors permit,... clearly operate at a greater and greater **rate** of intensity" (1973, p.81).

Such a **process** may of course put it on a self-destructive **path** if no **negative feedback** intervenes in due **time**.

On the contrary, a **negative feedback**, if not timely compensated by a positive one, will progressively **dampen** the system's **fluctuations** and may well finally block it.

0443

CIRCULARITY^{1) - 2) - 3)}

Character of any self-repeating **process**.

In order to take the **time-dimension** in account it would be more advisable to speak of "spirality".

Circularity is the result of **feedbacks**, specially the **cyclical** ones, corresponding to alternative positive and negative action, or **on-and-off processes**.

The circular **process** is essentially **self-referential** and basic for **recursivity**. It is generally functional and tends to generate either an **algorithm**, or a **structure**.

A degree of (frequently hidden) circularity is unavoidable in reasoning: St. KAUFFMAN, quoting W.V. QUINE, considers that "no hypothesis confronts the "world" alone. Instead, it confronts the world as part of an entire worldview of linked hypotheses plus statements about the experimental **situation**. Given a negative experimental result, something must be rejected. Either some hypothesis is wrong, or a **description** of the experimental **situation** is incorrect. But, as Quine pointed out, the **choice** of which hypothesis to reject is a *free one*. ... Different **choices** of which hypothesis to reject impinge on the whole web of hypotheses and laws. To maintain **coherence** in that web, we typically choose to salvage a central circularly interdefined **cluster** of hypotheses" (1993, p.17).

This situation appeared repetitively in science since the nineteenth Century: Non-euclidean geometries, corpuscular and undulatory theories of light propagation, quanta, relativity, **chaos**, etc...

As to **recursivity**, it corresponds to von FOERSTER's "**Eigen-**" **concept**, and to conceptual **closure**.

R. GLANVILLE observed that circularity is of utmost importance in **conversation** in G. PASK's sense, because it is : "...the basis for **understanding**, for the world as we (are) now seeing it, and for our seeing it" (1993, p.53).

Circularity is thus in no way to be confused with vicious circles. Particularly in systemic **semantics**, this dictionary uses circularity in a positive way to induce a kind of intra-dialogue in the user's mind by criss-crossing through the whole **semantic field**.

In correspondence with **organizational closure**, circularity is also a characteristic of numerous natural **processes** and systems, specially biological and ecological ones, as a result of the complex interplay of multiple **interconnected feedbacks**.

0444

CLADISTIC ANALYSIS^{2) - 5)}

A **taxonomic** tool in natural sciences based on the **clustering** of characters in individuals.

Those individuals whose respective **clusters** of characters are most similar are considered as the most closely related in **space** as well as in **time**.

If the individuals conform a temporal sequence, progressively growing **differentiation** from the type considered as original indicates the relative individual positions in the time sequence.

While cladistic analysis is basically applied in vegetal and animal **taxonomy**, it could be used in widely different disciplines, as for example the **evolution** of tools or that of related **languages**.

0445

CLANTHINK^{1) - 4)}

"An incorrect view held by all or almost all members of the **group** about something other than the complex issue being considered" (J. WARFIELD, 1994b, p.490).

Clanthink views are considered "obvious" by those who hold them. They frequently remain implicit and are never submitted to critical evaluation. This is one basic cause of so-called "**underconceptualization**" and **blindspots**, leading ultimately to unsound **decisions** and possible disasters.

Clanthink is particularly dangerous in international politics

WARFIELD comments: "Clanthink peaks when authority rather than exploration of logic drives activity. It is generally easily exposed when, in the questioning **processes** used, inconsistencies begin to appear in dialog, causing the **group** to make discoveries that are counter to what previously believed" (1995a, p.65,6).

In many cases, **action** based on clanthink is officially supported by the **group**, but can be covertly sabotaged by unconvinced hidden opponents. It also may face strong opposition from **stakeholders** who were not consulted (in some cases because they were suspected of not sharing the clan's views).

0446

CLASS¹⁾

"A collection of things having some common property".

T.A. and W. MILLINGTON state: "All classes of measurements, **objects**, persons, etc., must be defined between precise **limits** so that no one member of the class may, inadvertently, be put into more than one class" (1966, p.43).

However, in some cases, the practical impossibility to obtain such precise definition led L.A. ZADEH to the **concept of fuzzy set**.

0447

CLASSIFICATION³⁾

The ordering of a number of **elements**, **relations** or **systems** according to some pre-defined characteristics.

Classification is basic for the organization of **information** into frameworks and the typification of systems. It is however a difficult subject.

M. MARUYAMA clarifies some important points:

"... the classificational universe is characterized by its being divided into **categories** and subcategories... The **structure** of this universe is **hierarchical**. The **relations** are conceived in terms of the kinship in the **hierarchy** of superdivisions and subdivisions" (1966, p.55).

Classifications tend thus to be ordered in **hierarchical "trees"**, which supposes **criteria**... not necessarily accepted by all concerned people, because they are selected "ad-hoc" by the classifier.

Moreover R. SOKAL showed that different ways of **clustering** the **elements**, when all are endowed with characteristics of various types, lead easily to the possibility of alternative classifications (1974).

Another significant aspect observed by MARUYAMA is that: "The **relations** are static" (Ibid.).

Classifications are more **structure-oriented** than **process-oriented**.

However, "Classifications may be **polycriterial**, i. e., several classifications using mutually independent **criteria** may be surimposed" (Ibid., p.56), as for example, listing people by age and, otherwise, by alphabetic order of names, or birth place. Each specific **criterion** produces a selected **set**, but the different **sets** present intersections, which can be tabulated

or otherwise studied. For such purposes, multi-dimensional **matrixes** or **fractalized VENN diagrams** can be constructed (A. EDWARDS, 1989).

0448

CLASSIFIER²⁾

"A set of condition/action **rules**" (J. HOLLAND, 1992, p. 172)

Classifiers are necessary in **adaptive systems**. They work on **inputs**, detected from the **environment** by specific **sensors**. Any such input is matched with the behavioral **set of rules** proper of the system, according to a general "if... then" **rule**.

In HOLLAND's **model**, an **output** is produced and fed back to the **environment**. The obtained result may lead to an **adjustment** of the rules strength.

This is similar to the **back propagation algorithm** (HINTON, 1991).

Classifiers are basic, for ex. for **pattern recognition**.

0449

CLIMAX⁵⁾

The final **state** towards which an **ecosystem** tends asymptotically if no significant **disturbances** occur.

Of course, as any **ecosystem** exists in a specific **metasystem**, many significant **changes** may happen: a permanent **change** in temperature, or salinity, or humidity; or massive human interference with natural conditions, etc.

Perfect and definitive climaxes do not exist.

Climax could however be an approximate **cyclical model**. H. ODUM writes: "Systems which have some constant or repeating **patterns** with **time** are called climaxes by ecologists" (1971, p.79)

This notion is thus quite akin to **dynamic stability**, while suffering however from the same limitations.

0450

CLOSURE³⁾

The property of a system to maintain its own internal **order** and **identity** within defined and permanent **boundaries**.

The condition for closure is internal **recursivity** in the system, as demonstrated by H. MATURANA and F. VARELA.

F. HEYLIGHEN states: "Closure of a **substructure** within a larger **structure** means that the external **distinction** (between the substructure and its complement or **environment**) is enhanced, whereas the internal **distinctions** (between the **elements** or **components** of the **substructure**) are reduced. In other words, closure diminishes the **coherence** between the **substructure** and its **environment** while amplifying the internal **coherence** of the **substructure**". (1990b, p.488)

The word "**substructure**" (used by HEYLIGHEN in a paper about **representations** in quantum mechanics) could be usefully substituted by the word "system", since the concept of closure is very general.

Structural closure, in particular, implies the construction, reconstruction and repair of the **parts** of the system. As to **cognitive processes**, closure leads to their **circularity** (H.von FOERSTER – 1992, p.68)

Closure, in its organizational sense, "a logical attribute" in E. SCHWARZ words, "should not be confused with energetic closeness (or **openness**), a physical **level** attribute" (1993, p.3)

→ **Organization: a descriptive language**

0451

CLOSURE (Statistical)²⁾

"The necessity for the collective statistical **constraint** to close back on the internal, detailed **dynamics** of the **elements** of the collection".

This principle has been introduced by H. PATTEE, who explains: "... **hierarchical controls** arise from a collection of **elements**, but act on individuals of the collection. The spontaneous appearance of collective **constraints** must therefore be a statistical property of the collection, but its **control behavior** must act on the **dynamics** of individual **elements**" (1973, p.95-6).

Collective **constraints** are the factors that institute social **coherence**, precisely because they are at the same time reciprocal and global. **Ergodic phenomena** appear in this way.

This already shows in fish schools (D. RITZ, 1991) and in locusts flights, but becomes stronger in anthills or beehives and, in many new ways, in human societies.

0452

CLUB OF BUDAPEST¹⁾

E. LASZLO, in a paper in "Cybernetics and Human Knowing" (1997, p. 47-51) presents in the following terms the aims of this Club: "The Club of Budapest is dedicated to the proposition that promoting and facilitating the evolution of planetary consciousness is a vital aspect of our sustained well-being and individual as well as social development. It is an essential mission of our time".

He also writes: "The Club of Budapest is committed to promoting and facilitating a worldwide movement keynoted by the advance from thinking in terms of the existing limits to growth to the emerging chances of evolution" (Ibid)

A "Manifesto on the spirit of Planetary consciousness" was published with a number of signatories, among them the Dalai Lama and a number of prominent political leaders, two Nobel Peace Prizes and other spiritual and intellectual leaders.

Further information on the membership and activities of the Club is available from its Secretariat: Szentháromságter 6H -1014 Budapest-Fax 36-1-175-1885

0453

CLUB OF ROME⁴⁾

An international group of scholars and businessmen created in 1967 by the Italian businessman Aurelio PECCEI and whose aim is the study of human problems on a global scale.

The Club or Rome started by ordering to the Massachusetts Institute of Technology (M.I.T.) a study of the **trends** that may endanger our planetary society in the making.

This report, methodologically based on J. FORRESTER's **Systems dynamics**, was published in 1972. It stressed the **interactions** between five global critical factors: demographic explosion, food production; industrialization; exhaustion of natural **resources** and global contamination.

The quite pessimistic conclusions of the report triggered a flood of criticism, based partly on doubts about the soundness of the **methodology** and partly on ideological bents and biases. More reports were then ordered by the Club of Rome, using the same **method** for different **purposes**. The true aim of PECCEI and his friends was however not to make precise and irrefutable **forecasts**, but to draw worldly the attention on possible evolutive contradictions within our **mega-system** forming.

It is now recognized that we are all "Groping in the dark" (D. MEADOWS et al., 1982), after two decades of global **modeling**, because the tangle of interacting systems is so complex that it is hopeless to ever reach secure conclusions. Moreover, during the seventies, when the **models** were constructed, neither the implications of **deterministic chaos** were taken in account, nor the stochastic aspects of **dissipative structuration** in our obviously **far from equilibrium systems**. But at least we know it now and become more and more aware of the need to monitor **long term global trends**.

0454

CLUE¹⁾²⁾

Any **observation** or **information** that contributes to a better **understanding** of a **process** or **situation**.

Of course, a clue gains its value only for the **observer** who is able to give it a **meaning** within a wider **frame of references**.

Photographic plates stored in a closed drawer that became veiled side by side with a sample of a yet not well known mineral became the first clue of this new **phenomenon** at the end of the 19th C.

But the clue made sense only for Becquerel and the Curie's because they already knew about ionizing radiations. Quite numerous scientific discoveries resulted in the same way from a clever interpretation of some clue.

In a lighter vein, clues were always meaningful for the keen eyes and acute **perceptions** of Sherlock Holmes...but only for him!

→ **Causality; Effects (side); Predictive event; Serendipity**

0455

CLUMPERS and SPLITTERS¹⁾³⁾

This amusing expression about two quite different types of minds (New Scientist, Nr. 2211, November 6th, 1999) surely deserves being included in this work.

"Clumpers" would be the authors of grand unified philosophical or scientific theories. Newton or Darwin would be paradigmatic examples. As to "splitters", the enormous majority of researchers in any discipline, they would be the hardworking, more or less anonymous toilers, painstakingly collecting myriads of small **data** or reduced specific **models**, which would one day allow for some breathtaking synthesis by some "clumper"... as for example the treasure of specific **data** obtained by numerous chemists, which were finally ordered by Mendeleiev, the clumper, in his famous periodic chart.

Systemists tend to be clumpers, but it should be very risky for them to ignore the laborious works of the splitters. As to the splitters, their work gather more sense and **significance** within the **mental frame** of already existing wide embracing theories... even if their discoveries may well lead to some shattering conceptual revolution.

0456

CLUSTER^{1) - 2)}

A more or less interacting gathering of **elements** within a common **environment**.

Clustering is the result of existing **patterns** of circulation within the **environment**, which tend to create more or less **homogeneous** local conditions, as opposed to global **heterogeneous** ones.

Clustering can as well be more or less local, i.e. in **composite systems** many local proto-clusters may coexist, with only a very loose **interaction** (if any) until their concentration increases up to a **critical threshold**, where suddenly a global cluster appears through part or whole of the **region**. The increased closeness of the **elements** tends to trigger more **interactions** among them. This may lead to a higher **level of organization**, which in turn may become stabilized (**frozen cores**), or not.

Clusters can be observed among such diverse kinds of **elements** as stars and galaxies, plants and human settlements, political **organizations** and systems of ideas. Clustering is thus an important systemic **concept**.

0457

CLUSTER ANALYSIS²⁾

A method used in the study of **parallel processing networks** to establish in a global way what **information** the **nodes** are sensitive to in a **learning rule** (Adapted from W. BECHTEL & A. ABRAHAMSEN, 1991, p.304).

Such a method is more practical than trying to study the **sensitivity** of all **nodes** separately.

0458

CLUSTERING²⁾

The progressive ordering of **relationships** within a flow of **information**

(**Information** is given here its most extensive meaning).

Such a **process** is spontaneous in young animals, and in babies, still more so when reacting to more elaborated **stimuli** from grown ups.

Any **relationship** in itself contains the basic features of **meaning**. This is made very clear by STEINBUCH's **learning matrixes**, with the transit from a **learning phase** – which connects a specific **stimulus** or experience with a specific **signal** (being this also the basics for conditioning) – leading to a **knowing phase**, which in turn opens the way to use acquired **knowledge for action**.

Recent advances in **robotics** are now also oriented to "...make **machines** that acquire meaningful **representations** of the world with as little intervention as possible"(D. GRAHAM-ROWE, on P. COHEN's research – 2002, p. 22-23). We could be on our way to self-constructed **artificial intelligence**. (see also: **Artificial Life**)

As noted in very general terms by F. DRETSKE (1981), **meaning** comes from **interactions** with the **environment**. It derives thus primarily from a more or less high quality of **perceptions** – something that F. ROSENBLATT already had understood with his **perceptron** (1961 and 1962). Experiencing with the **environment** is also a core feature of **autopoiesis**. Clustering, finally, as a **process**, is closely related to the construction of **constraints** in ASHBY'S sense.

0459

CO-ADAPTATION

→ **Adaptation (Reciprocal); Red Queen Evolutive Parable**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0460

COALESCENCE¹⁾

A **process** of progressive concentration of formerly scattered **elements**, centered on a **nucleus**.

Coalescence results of **random** movements of scattered **elements** which casually produces some local concentration. Thereafter this core or "seed" starts to act as a center of **aggregation**

→ ("fractal aggregation", "nucleation mechanism")

It is a **percolation**, or an **emergence phenomenon**.

Coalescence is quite general and is verified in many cosmic, biological, economic and social **processes**.

0461

COALITION¹⁾⁴⁾

"Attractive **interaction** between a pair of **functions** increasing the **probability** that they follow each other in **space** or **time**" (R. FIVAZ, 1996, p.143)

The opposite phenomenon is **competition**.

0462

CODE^{1) - 2)}

A specific **set** of **signals** and their **rules** of **interconnection**, forming a **communication** system used to transmit **messages**.

There exists a great **variety** of codes.

Some have a material base, as for example the old flags code in the navy, or any printed **alphabet**. Others use modulations of some form of **energy**, as for example sound waves or electro-magnetic ones.

There are also more abstract types of codes, all of them somehow related with **transmission** of some kind of **information** between sentient and intelligent beings.

Written or spoken **languages**, with their specific phonemes, morphemes, vocabularies and syntaxes, are of this type, as well as logical and mathematical **languages** and some more specific scientific sub-**languages** used in specialized disciplines.

For any **transmission** of **information** at the mental **level**, both an abstract code and a physical one are generally needed in a sequential way.

The use of any code supposes that it is known by **receivers** as well as by senders.

Codes must be sufficiently permanent and rigid in order to remain useful.

0463

CODE (Analogic)²⁾

A code based on pictures, **graphs**, etc... with **magnitudes** related to some defined **scale**.

0464

CODE CONSTRUCTION
(In human conversation)⁴⁾

R. GLANVILLE observes that the notion of **coding** is mostly "seen as what spies do, what Alan TURING showed us how to handle and crack/decipher"(1997, p. 60). He observes: "These codings are codings of literal **connection** and **transformation** in which one sequence may be represented exactly by another, which may in principle be de-coded provided the encryption key is to hand. They are in effect, **tautological**".

So, this type of codes, once constructed, is invariable within the limits of its base-**algorithm**. However this is not so in the case of **human communication**. Once past the bare **rules** of the grammatical or syntactical use of a specific spoken **language**, human **conversation** goes to a second order codification which is progressively constructed between the conversants and is ever evolving. The general concept of interpersonal code construction was developed by Gordon PASK in his very last paper (1996, p. 350-361) wherein he derives the basic idea from H.von FOERSTER's **self-organization** concepts as the "Progenitor of Conversation and Interaction Theories"

GLANVILLE's essay stirs deeper into the subject. He concludes: "By involving the **observer** as conversationalist, by not relying on prior, agreed **meaning** (However could we agreed it?), by insisting that meaning is personal and is not communicated, by keeping the form of **communication** separate from the **content**, **conversation** provides a much more basic, much more general, much less demanding, much more cybernetic **understanding** of how **communication** can happen in the world of today"(Ibid, p. 64)

0465

CODE CREATION^{1) - 2)}

The extraction of significant **algorithms** from redundant **information**.

An **alphabet**, for example, is the most constrained collection of sounds used in a spoken **language**, or also graphic **representations** of these sounds in its written form. (or should be, since in french for example nasal sounds as "on", "an", "un", etc..., are not represented as a single letter in the **alphabet**).

This kind of **compression** is also obvious in the "**part-for-whole**" coding explained by G. BATESON: "The verbal **message** 'It is raining' is to be seen as a **part** of a larger **universe** within which that **message** creates **redundancy** or **predictability**" (1973, p.391).

This **universe** must of course have been learned before it can be used as a **frame** for code creation.

There are many types of codes: **digital**, **analogic**, **iconic**, **metaphoric**, etc...

0466

CODE (Digital)^{2) - 5)}

A code based on positions in a **matrix**, expressed in **bits**.

G. BATESON gives the following examples: "... the telephone exchange is a purely digital computer. It is not fed with **magnitudes**, but only with names of positions on a **matrix**". However, "... Cartesian **graphs** are **analogic**" (1973, p.343)

0467

CODE DUALITY²⁾

J. HOFFMEYER and C. EMMECHE introduced this notion (1991). Hoffmeyer writes: "Code duality refers to the fact that **living systems** always form a unity of two coded and interacting **messages**, the analogically coded message of the **organism** itself and its redescription in the **digital code** of DNA. As analog codes the **organisms** recognize and interact with each other in the ecological **space** giving rise to a horizontal **semiotic system** (the ecological **hierarchy** of Stanley SALTHER (1985), while as digital codes they are passively carried forward in **time** between generations (after eventual recombination through meiosis and fertilization in sexually reproducing species). This is of course responsible for nature's vertical **semiotic system**, the genealogical **hierarchy**"(1998, p. 34)

0468

CODES (Linguistic and Semantic)^{3) - 4)}

A consensual **set** of **meanings** among a number of emitters or senders and **receivers** which allow them to exchange **information** understandable by all of them.

No **information** can exist without a **language** which provides a **semantics** (apart from the physical **codings** already referred to). **Semantic coding** is also a **process** of **consensus**: a number of senders and **receivers** must reach a general agreement about the meaning of words (groups of sounds) and sentences (group of words).

For example, the users of this dictionary must necessarily share with us the basic linguistic **code**, English, before being able to study, admit, reject or accomodate for their own use the systemic **metalanguage** here proposed. To make this point perfectly informative, here is a sentence in a **language** that most readers probably do not know: "Mutoto alivunja sahani moya". The only **information** therein contained for someone who ignores kiswahili, is that the sentence, if not fanciful, must contain some hidden **information**.

Linguistic codes are generally shared by a definite human group, in **space** and **time**. Every **language** conveys **information** in a specific and peculiar way. This is why the Italians say: "Traduttore, traditore". It is really very difficult to find a non-scientific word whose

meaning is identical in various **languages**. Witness, for example, the quite different sense given to the word "democracy" in different nations. Moreover, **meanings** vary with time: they are not only culturally-subjective but also temporally-subjective.

All this is true even for most of the **scientific language**. While we have a unique rigorous and universally imposed **meaning** for units like the hartley, the ohm or the joule, we are quite less sure about **meanings** when we speak of "determinism", "autonomy", "randomness" or "information", for example.

0469

CODING²⁾

The physical and/or **semantic translation** of a **message** into a precisely defined **code**.

In fact, **communication** entails successively **encoding**, **transmission** in the **code's language** and **decoding**.

0470

CODING (Selective)²⁾

Mechanism or device through which only some specific **inputs** are recognized as compatible with the system and thus accepted.

According to D. KATZ and R.L. KAHN: "Through the coding **process** the *blooming, buzzing confusion* of the world is simplified into a few meaningful and simplified **categories** for a given system. The nature of the **functions** performed by the system determines its coding **mechanisms**, which in turn perpetuate this type of functioning" (1969, p.96).

The basic coding of any system is defined by the characteristics of its original constitution (See: **Archetype**)

Moreover, coding acts as a powerful **constraint**, limitative of the numerous possible **disturbances** brought by the **environmental variability**. However, there is a price to be paid, i.e. the impossibility for the system to perceive more than a small fraction of its **environment**.

Man solved partly this problem by creating **codes of coding**, as for example those which allow for the indirect **perception** (by their effects upon **readable codes**) of numerous radiations or microscopic **objects** or very distant astronomical **objects**.

0471

COGNITION^{1) - 3)}

The acquisition of an ordered and operative **understanding** of ourselves and our **environment**.

H. MATURANA thus states the **autopoietic** view on cognition: "... reality and its cognition had to (i.e. have to) be accepted as a mode of **operation** of the nervous system as a closed **neuronal network**" (1979, p.25).

He also writes: "**Living systems** are cognitive systems, and living as a **process** is a **process** of cognition" (1980, p.13).

As to "reality", this view may seem somewhat extreme. We should perhaps speak here of "perceived reality".

As to cognition, we seemingly cannot do without some explanation about the **autogenesis** of such "closed **neural networks**".

Also von FOERSTER presented "... evidence that cognition is a continuously recursive computation of **descriptions** of reality" (K. WILSON, 1979, p.32).

This amounts to an **analogy** of the **brain** as a biological **computer**. This **analogy** however should be taken with much care, because the **brain**, in any case, is obviously not a simple **sequential computer** and apparently **constructs**, in some not yet very well understood way, its own **recursive algorithms**.

0472

COGNITIVE BLINDSPOT³⁾

Our incapacity to perceive this that we do not perceive.

This notion, introduced by von FOERSTER, using the **metaphor** of the ocular blindspot has also been formulated by:

- the French economist J. FOURASTIÉ, who spoke of the "ignorance of ignorance".
- by G.de ZEEUW, who uses the term "**invisibility**".

Cognitive blindspots are very dangerous, because they leave us in the false security that what we know covers the whole of what can be known. This does not allow us to see the narrow limitations of our **knowledge**.

→ **Blindspot**

0473

COGNITIVE COMPRESSION³⁾

The reduction of the **complexity** of conceptual **structures** through **categorization**.

This **concept** has been introduced by P. CHURCHLAND.

Cognitive compression is operated, or at least expressed through **language** which, according to A. and H. DAMASIO "... helps to **categorize** the world and to reduce the **complexity** of conceptual **structures** to a manageable scale" (1992, p.63).

Thus a **process** of **abstraction** (also described by the **structural differential** of A. KORZYBSKI) becomes practically operative as "the cognitive economies of **language** - its facility for pulling together many **concepts** under one **symbol** - make it possible for people to establish even more complex **concepts** and use them to think at **levels** that would otherwise be impossible" (Ibid).

The authors give two examples, widely different.

The first one is the general **concept** of "screw-driver", which does not create real difficulties. The second one, however, "democracy", implies some serious problems, as would any *abstract* "**label**" (to use KORZYBSKI's term), because the content of such compressed **categories** may be - and frequently is - dubious, as open to cultural or ideological manipulation (propaganda, brain washing, etc...).

0474

COGNITIVE DISSONANCE³⁾

M. TODA uses this L. FESTINGER's **concept** (1957) as follows: "... one may get an **information** which is so out of **range** of his expectation that the **validity** of his **cognitive simulator** may be seriously doubted... On the other hand, the **structure** of the **environment**, particularly that of a society, may not remain the same in the long run, and the **validity** of the frozen **cognitive simulator** will be degraded accordingly" (1976, p.83).

"frozen" is a very significative adjective in this case: it transmits with full clarity a critical aspect of mental **algorithms**, which need to be stabilized in order to become useful, but may altogether become counter-**adaptive**.

TODA makes the point: "So once one starts to "defend" his **cognitive simulator**, the need for defence will increase in frequency following the **validity** degradation, which will in turn decrease the real **information input**, and this may very well be the beginning of a vicious circle" (Ibid).

0475

COGNITIVE MAP^{1) - 3) - 4)}

"The mental **image** or **representation** made by human individuals and **groups** of their **environment** and their relationship to it" (LASZLO, 1993, p.315).

J.J. GIBSON, on the basis of the physio-psychology of visual **perception**, criticized this **concept** of a map "... supposed to exist in the mind" (1986, p.199). In his view, the **understanding** of the **environment** is a progressing **process**. This does not seem necessarily contradistinctive to the **map model**. While our **perception** is indeed sequential, revealing **meaning** as we go, this **meaning** was generally learnt and stored, i.e. **mapped** from previous experiences. We do not know what we are going to find out, but we are prepared to understand the **meaning** of the clues, as we are going on.

According to A. LASZLO, a cognitive map: "... involves not only the rational aspects of attitudes and **behaviors**, but also the **value** and belief **components** that shape human **perception**. As such, human cognitive maps signify the particular **representations** or **images** of social and physical reality formed in the **brain**" (Ibid).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

He adds: "This map allows us to be consistent in our thoughts and **actions**. Factors of heredity (the fixed internal **environment**), **behavior** (characteristics unique to the individual), and social and physical **environments** (**variables** external to the individual) co-produce a general conception of the nature of the world and a particular **configuration** of **value**-principles that is more or less unique for each of us" (p.316).

And: "The individual cognitive map is shown to be the result of the effect of the **environment** on the **behavior** and the heredity of the individual, of **behavior** on **changes** in the **environment** and heredity, and of heredity on modifications in **behavior** and the character of the **environment**" (p.316).

Moreover: "To prioritize and preserve this **information**, cognitive maps must involve '**values**'. **Values** are **symbols** that serve to record **phenomena** and that catalyze reactions to them. On an individual **level**, cognitive maps are conditioned by the **values** and beliefs that are dominant in society at the time. By internalizing **values** derived from cultural **contexts**, individual maps incorporate a certain amount of developmental leeway" (p.318).

In other words, the establishment of cognitive maps depends on **values** as **templates** leading to the construction of more or less stabilized **algorithms** for the **organization** of **autopoietic behavior**.

0476

COGNITIVE MAPS (Societal)^{1) - 4)}

When an important number of individuals share quite similar cognitive maps, such a **consensus** leads to the shaping of kinds of societal cognitive maps that, in A LASZLO's words "... serve as vehicles for societies to probe **environments** quickly and effectively", giving them "the means ... to keep pace with accelerating **rates of change**".

However, when these societal maps are not anymore "in sync" with socio-cultural **dynamics**... they tend to perpetuate singular **responses** that no longer fit with the realities of a changed and changing **environment**" (1993, p.318).

Such **situations** lead to revolutionary upheavels and/or to individual psycho-pathologies, which can readily be observed in our present world reality.

0477

COGNITIVE MODEL³⁾

A cognitive model is in fact an intricate **array** of interconnected functional characteristics of the human **brain** directed at the understanding of so-called "**reality**". The model would depend on specific modes of **perception**; ways to construct internal **frames of references**; **memory** (a set of devices to store such frames in a more

or less permanent way);; probably inner imaging and **languages** to communicate with other **observers**.

The comparative value of different cognitive models is a controversial matter under at least three aspects:

- Different **cultures** understand cognition in different ways. Acupuncture and ayurvedic medicine are examples as compared to western medicine
- **Religion** based models of cognition cannot be equated to rational and scientific models. There are no unquestionable comparative **evaluations** of bouddhist psychology, hindouist yoga, coranic or christian teachings
- Even scientific cognitive models have evolved deeply in the western world for example from rational and **linear causality** and Cartesian **method** to let us say-cybernetic **nonlinearity**, so called **holism**, auto-poietic **closure**, Popperian refutation and/or Heisenberg's **indeterminacy** (among others)

→ **Three R's of hard sciences**

0478

COGNITIVE OVERLOAD^{1) - 3)}

A **level of information** that cannot be registered or assimilated because it exceeds the **receiver's** capacity.

J. WARFIELD stresses that "The rate of presentation of **information** for **processing** by the human mind must be controlled, to avoid cognitive overload" (Pers. comm.)

There is a **short-term limit** to idea-**processing** capacity, and probably a **long-term limit** to **assimilation** capacity, i.e. to the insertion of new **concepts** and **models** within global ordering **schema** and **frames** in the mind. This increases the risk of losing any **capacity** to understand complex **situations**.

When such **limits** are crossed, part of the **information** becomes lost and, in extreme cases, general confusion may ensue. The problem is becoming more acute due to the present **information** glut in our technocratic culture.

Cognitive overload seems now a definite risk not only for individuals, but altogether for **organizations** and **sociosystems**.

0479

COGNITIVE PANORAMA¹⁾²⁾

A conceptual superstructure that defines and identifies topics as logical places, displays relations and **connections** within these topics or **issues**

This concept has been introduced by H. BENKING. The following comments are Benking's explanations, plucked from a series of papers and lectures (see bibliography)

"The cognitive panorama is a metaparadigm to counteract cyberculture's anticipated impact due to its: 1) open-ended universality, 2) loss of **meaning** 3) loss of **context**"

It is now obvious that we risk drowning in an ocean of incoherent **data** which could lead us to total conceptual **anarchy**.

According to Benking, the proposed cognitive panorama "allows us to embody and map concepts in their context and develop common **frames of reference**"

Such a conceptual superstructure "helps us to locate and become aware of: 1) what we know or miss, 2) where we are and what we think, 3) where we miss, underuse or manipulate **information**. By avoiding a "flat" chaotic mess of data which leads to the known "lost-in space" syndrome, we actually define **cognitive spaces**.

Through reflection on conceptual positions, outlining and embodying situations or topics (logical places or containers) we can follow meaning into embodied context and **semantic spaces**, and also scrutinize abstract "realities" by exploring participatory and collaborative approaches.

→ **Conceptual navigation; Convertibility of meanings; Ecocube; Harmonization; Knowledge map; Underconceptualization**

0480

COGNITIVE PROCESS^{1) - 3)}

H.von FOERSTER writes: "No theory of cognitive processes can be constructed merely from sensorial **data**"... which he thus explains: "The excitations of a nervous **cell** code only the intensity, but not the nature of the excitation. **Codification** is only 'such and so much' in this place of my body, and not 'what'". (1992, p.58).

If so, we are left with a need to bridge the chasm between perceived nervous impulses and their **meanings**. This is the riddle that **constructivism** is trying to solve, through interconnected **concepts** like **circularity**, **operators**, **closure** and **algorithm construction**.

The cognitive process is now also explored through **artificial intelligence** research. A number of interesting papers By R.L. BROOKS, P. MAES and others, from a symposium on "Integrated Cognitive Architectures", were published in SIGART, Vol. 2, Nr 4, 1991.

Among the important aspects of the cognitive process, these studies emphasize: perceiving, interconnecting **perceptions**, acting, registering the positive or negative results of **action**, keeping these results registered for **further reference** (i.e. becoming able to use them selectively in future **action**), improving **behavior** (i.e. obtaining better results from **action**, based on cumulative experience).

This kind of progressive build up of cognition, integrated from **perception**, **action** and **memory** could be the bridge between old behaviorism, **constructivism** and **autopoiesis**.

K. KRIPPENDORFF describes the cognitive system as follows: "A **construct**, **map** or maze involving a collection of interconnected items of **knowledge** or beliefs held by an individual about himself, or about his physical or social **environment**, including the cognitive system of others" (1986, p.12).

The cognitive system must however be **self-constructed**, within the **limits** of inherited biological (and possibly cultural) **closure** by progressive **constraints** which channel and limit original potential **variety**.

0486

COHERENCE¹⁾

The stability of **functional** and **structural relations** between **components** or **subsystems**.

Z.W. WOLKOWSKI recently presented a synthesis of the uses of the coherence concept in numerous disciplines from physics to biology and social sciences, giving very numerous examples (only French ones, however).

He states that: "It deals with **space-time** relationship, **resonance**, **synchronization**, interference, harmony, **compatibility** and **integration**" (1992, p.63).

The concept of coherence may be considered as a strong systemic **isomorphism**.

0487

COHERENCE CONDITION^{1) - 2)}

The necessity for any **network** to maintain more or less stable permanent partial and local **circuits** in order to remain able to perform.

This **concept** has been developed by brain neurologists (W. SINGER, C. GRAY), but seems basic for the satisfactory working of any **network**.

D. HEBB's rule and St. KAUFFMAN's "frozen cores" help to explain how the **brain** can maintain itself as a going concern, being sufficiently (but not excessively) "**joined**", in ASH-BY'S terminology.

Coherence, in this precise sense, is however clearly an unavoidable necessity for any performing **network**, as for example **sociosystems** or **distributed multi-agents systems**.

0488

COHERENT ORGANIZATION

→ **Organization (coherent)**

0489

COHESION^{2) - 4)}

The result of selective interactions between the **elements** or **subsystems** of a system.

"Cohesion is a **gestalt** property of a system" (M. BUNGE, 1988, p.7).

In effect any system is governed by a global dynamic law (J. THIERIE, 1990, p.442).

M. BUNGE comments: "Interestingly enough, cohesion turns out not to be proportional to overall participation. Instead, it is maximal for middling participation – which is reasonable, since nil participation is incompatible with communality, whereas the participation of everyone in everyone else's affairs results in **anarchy**.

"Cohesion...emerges and submerges from **interactions** among the members of the group. It is a good illustration of the claim that **systemism** is a sort of synthesis of **holism** and individualism" (1988, p.7).

This explains altogether why **complex systems** are **semi-decomposable** (H. SIMON, 1958). Cohesion is centered around a **set**, more or less specific and localized, of basic **interactions**, eventually at different **hierarchic levels**.

→ **Hora and Tempus parable**

0490

COHESIVENESS^{2/4)}

The degree of **cohesion** in a **group** of **elements** or individuals.

In human groups, cohesiveness depends mainly of the communication **competence** of their members. The development of increasingly numerous and complex societies is obviously parallel to the development of spoken and other **communication languages**.

0491

COHORT^{2/4)}

A set of individuals as members of a **population**, sharing some peculiar characteristics.

It could be, for example, individuals born the same year, or those who make up a migrating **swarm**.

The numerical reduction of cohorts tends to impair the **stability** and, in some cases, the **survival** of a population, or of some specific characteristic of the same.

The notion is significant in **ecology**, in genetics and in **sociology**.

0492

COLLAPSE¹⁾

"A **catastrophic** change in a system which becomes, initially at least, overexcited such that some of the **parts** overstep the **constraints** of systems **rules**" (T.F.H. ALLEN & T.B. STARR, 1982, p.263).

"Overstep" is more likely to be **overshoot**.

ALLEN and STARR consider collapse as "characteristic of an overconnected system... which has so many **connections** between its **parts** that it is **unstable** and is wont to undergo uncontrolled **change**" (p.263-274).

This can be understood as the result of an excessive narrowing of the system's **stability limits** and **thresholds**, which enhances the probabilities of **overshoot**.

0493

COLLECTIONS²⁾

The status of collections of objects as related to systemic concepts is somewhat ambiguous (R. PATON, 2000, p. 147-159)

There are different types of collections, reflected in collective terms.

A heap of sand has merely vague systemic undertones, and this only since it has become used in relation with **chaotic dynamics**, **unstable equilibrium** and **power laws**. In these cases the systemic **behavior** of the collection is generally implicit and manifests itself through fleeting episodes.

A **swarm** of locusts or a **school** of fishes, or a **colony** of ants already show more constant common behavior, corresponding to variable degrees of **organization** emerging of reciprocal **constraints**.

A similar type or more or less coherent systemic organization appears in collections of humans when not very permanent: conferences or congresses for example.

Biology offers us examples of collections which have an organizing power within **complex systems**: the **genome** seems a clear case.

In short, collections seem to be a kind of pre-requisite **situation** or **state**, while their systemic value depends on the nature- and in cases, the **evolution** (see for ex. **Dictyostelium discoideum**) of the **relationships** among the **elements**.

→ **Stigmergy; Zero system**

0494

COLLECTIVE BEHAVIOR⁴⁾

A similar and simultaneous behavior in a numerous **group** of individuals of a same species.

Collective behavior can be observed in all societies, from amoebas to human groups. Coordination of moves or other activities results from some specific factor as for example **pheromones**, or reciprocal visual **perception** (in fish **shoals**, for example), or gestual or spoken **language**.

Normally collective behavior is reinforced by repetitive **action** that works as a positive **feedback**. This can even lead to exponential or massive **effects** (swarming, communal building, in insects...and people, panics, etc)

Curiously, in some cases some unfavorable factor, a **negative feedback** can lead to the reduction, or even the suppression of some **behavior**. C. Defrain and J.K. Deneubourg give the example of ants trails abandoned when a source of food is nearly exhausted or if some obstacle or danger intervenes. (2000, p. 147)

0495

COLLECTIVE BEINGS¹⁾⁴⁾

"Collective Beings are intended to be multi-systems having **components** contemporarily belonging to more than a single system, making emergent different systems even simultaneously. The **concept** particularly applies to interacting autonomous **agents** dynamically using same **cognitive models**" (G. MINATI, 2001)

Minati connects this concept with normative **ethics**.

→ **Human systems (rule-bound); Metalevel; Network**

0496

COLLECTIVE OBSERVER

→ **Observer (Collective)**

0497

COLONY^{1) - 4)}

A group of **elements** or individuals of the same type, which coexist in a correlated way, but are still able to maintain their own **autonomy**, or, at least, to recuperate it.

A colony is not an **integrated system**, nor even a **semi-integrated one** on its way to **organizational closure**. **Elements** or **subsystems** retain their **autonomy** and their **autopoiesis** at their own **level** (F. ROBB, 1989, p.61).

In a colony, even eventual specialization of the **elements** does not imply **irreversibility**, nor definitive subservience to the **whole**. For example, some colonies of poplar trees may become very extended and quite old. But even then, the individual trees, while all offsprings of the same original one, do not become functionally differentiated.

The case is somewhat different with colonial animals, like sponges where structural **differentiation** do exist, but can be reversed.

At the extreme limit of colonial existence, the social **phase** of the amoeba *Dictyostelium discoideum*, is irreversible and, after sporulation of some of the individuals at the top of the **structure**, all the others die and, when favourable conditions reappear, there is a reversal to individual existence, starting from the dormant spores.

It remains arguable if, somehow, a colony-stage may or may not open the road towards an **autopoietic system**. In effect, there seems to exist a progressive **transformation** in the **organizational dynamics** of social insects. In D.M. GORDON's words: "It seems that **task allocation** is channeled into more consistent **patterns** in the older colonies". More mature ants colonies also seem to learn how to prevent reciprocal encroachment on their foraging **range**. (1995, p.53).

According to some eco-ethological cases studies "...the **costs** and benefits of coloniality vary markedly with such factors as group **size**, the **frequency** of predation, exposure to parasites, etc...". P. Corning gives numerous examples in one of his papers on **synergisms** (1998b, p.21).

These intriguing features could be of very high interest for the study of the present **process of organization, conflict** avoidance and globalization of the human species.

For interesting observations about colonies, see J.T. BONNER (1955, 1988).

0498

COMBINATORIAL ANALYSIS^{2) - 5)}

The mathematical study of all types of combinations and permutations, and their properties.

The subject is closely related to factorials, **graphs theory, groups theory, lattices and matrixes**.

K. KRIPPENDORFF refers himself to "Combinatorial explosion" which "occurs when a small increase of the number of **elements** that can be combined increases the number of combinations to be computed so fast that it quickly reaches computational limits (**BREMERMAN's limit**)" (1986, p.12).

0499

COMBINATORICS⁵⁾

"That branch of mathematics concerned with the **variety** of combinations of **elements** that are possible within given **constraints**" (KRIPPENDORFF, 1986, p.12).

This includes "the number of **selections**, permutations, arrangements, **patterns** and **organizations** a system is capable of. Combinatorics is central to statistics and **information theory**" (Ibid).

The existence of **constraints** defines the **algorithmic** characteristics of the combinatorics.

Not all the theoretically possible combinations are practically possible.

→ **Factoriality; Zerosystem**

0500

COMMAND¹⁾

An imperative **message** whose aim is to modify the **behavior** of the **receiver**.

V. TURCHIN writes: "The **meaning** of a command is the way it changes the **state** of the **receiver**. In the classical limiting case a command leaves the **receiver no choice** at all, so that the **action** of the **receiver** is uniquely determined by the command. Computer **languages** can serve as an illustration" (1993, p.14).

The concept of command should be stripped from its originally limited psycho-social **meaning**.

On the other hand, TURCHIN also observes that in many practical cases, "the command leaves *almost no choice*" to the **receiver** (Ibid).

The sender of the command can never be sure that – due to the **time lag** in its **transmission**, as for example in a tele-piloted rocket – its general conditions of **validity** will remain changeless (or even that they were correctly evaluated).

0501

COMMENSALISM^{1) - 5)}

A relationship between two or more **organisms** which benefits one, or both, or all without harm for any of them.

Commensalism is thus a non-**parasitic** relation.

This concept comes from botanics and zoology.

Commensalism is an interactive ecological **phenomenon**. Its scope is more limited than **symbiosis** or **parasitism**. However, as such, it could be considered as a first step toward a closer individual or collective **relationship**, leading eventually to more complex **social systems**.

0502

COMMON SENSE¹⁾⁴⁾

The global intuitive way of **understanding** that results from the progressive **integration** through **learning** or **training**.

Common sense allows for quick understanding of, and **response** to many **situations** and **behavioral experiences**. It may sometimes "save the day" in critical circumstances that do not allow for long research or reflections.

The acquisition of common sense - which amounts to implicit immediately available **knowledge** for practical **action** - starts at birth and never concludes.

Common sense is however at least partly accorded to the particular **culture** in which any individual find himself inserted.

And, unfortunately, common non-sense also exists and may spread quite widely

0503

COMMONS^{1) - 4)}

Those **resources** considered of common anonymous ownership.

This very old notion was reintroduced and generalized by G. HARDIN in a famous paper (1968, p.1243).

In E. LASZLO words: "When the size and **resources** of the commons are limited, individual **competition** intensifies and, for a **time**, permits the enterprising actors to draw further profits. But eventually they exhaust the commons and bring about their own downfall" (1978, p.86)... and probably everyone's downfall.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

As stated by W.W. HARMAN: "Microdecisions regarding utilization of **resources**... which are reasonable from the viewpoints of corporate **management** and stockholders, developers and local governments, result in macrodecisions of **resource** depletion, **environmental** degradation, urban **crowding**, which are unsatisfactory to society at large" (1972, p.87). This was considered a key issue by HARMAN in 1972: It still is and practically nothing is done to confront this challenge.

We have nowadays multiple examples of this problem at every **level** of human **groups** and it becomes now also a planetary one: The global **interrelation** between the **ecosphere** and the **sociosphere** could very well cross a **threshold** of total **instability**.

The commons, in **process** of exhaustion as **sources**, are also in **process** of saturation as **sinks**.

0504

COMMUNICATION ^{1) - 2)}

The task of producing at one point of **space**, a **message** that was created at another point.

"The **interaction** between systems or **parts** of a system using a pre-arranged **code**" (J.Z. YOUNG 1978, p.290).

This definition emphasizes the preliminary necessity of a shared **code**, which seems obvious.

Which is however not always so obvious is that this **code** is generally quite complex, offering physical, perceptive, **semantic** and cultural aspects, in accordance, moreover with the characteristics of the **environment** shared by the communicating systems.

J.van GIGCH makes the point: "When Communications Sciences were dominated by SHANNON's work in Communication Theory... the human communication **channel** provided this scientific discipline with its **metaphor**: a system grounded in telephone and electronic technologies. However, this school of thought has been superseded and displaced by a more comprehensive view which embraces not only the **syntactic**, but also the **semantic** and pragmatic views of communication. Therefore, this field can be associated with the **metaphor** of a relational exchange system designed to influence" (1993, p.50).

As observed by K. KRIPPENDORFF, the former view of communication as merely the **transmission** of **information** from a sender to a **receiver** (SHANNON) has now been extended to **interactions** within complex **networks** with numerous **feedbacks** among **elements** or participants.

Indeed, some kind of communication is the unavoidable condition for any **interactions**, starting at the very physical **level**, and for **sociality** in **ecosystems** and in **living systems**.

→ SHANNON limit

0505

COMMUNICATION and BEHAVIOR ^{1) - 4)}

D. Mac KAY states: "The object of communication is to select some particular conditional readiness in the recipient from the range of **states** that are possible" (1963, p.28).

A specific behavior may be thus elicited, but it may also remain potential, or be different, depending of complementary circumstances.

Mac KAY gives the following example: "... someone is telling you: 'it's raining'. What happens? You may be immersed in a book, and may not even feel inclined to grunt an acknowledgment. But this does not mean that your **understanding** of the **message** had no effect on you. If a sudden call comes for you to go outdoors, for example, you may be ready to reach for umbrella or mac" (1963, p.22).

Thus communication acts as either a potential or effective **trigger** of behavior. Ethological research shows this to be also the case with animals.

Communication is always in some sense an attempt by an **sender** to modify the **behavior** of one or various **receivers**. Communication is obviously a social **phenomenon**. In G.R. JOHNSON's words: "Communication is found wherever social life is found, from microorganisms to insects to humans. Some times these **processes** are dependent on visual clues... Sometimes they are based upon chemical clues... (or) anchored in auditory clues. And sometimes other clues are used – for example, tactile and electrical" (1992, p.1142).

0506

COMMUNICATION as CONTEXT depending ^{1) - 2)}

BATESON bluntly states: "... without **context**, there is no communication" (1973, p.378) and explains his view through an example: "A phoneme exists as such only in combination with other phonemes which make up a word. The word is the context of the phoneme. But the word only exists as such – only has '**meaning**' – in the larger context of the utterance, which again has **meaning** only in a **relationship**" (Ibid). He could have added: "...and in a specified **language**".

D. BOHM and F.D. PEAT express a very similar idea when they write: "In communication, **meaning** unfolds in the **structure** of the **language**, and **meaning** unfolds into the whole **community** and unfolds from the **community** into each person... "The explicate form of all this is the **structure** of society, and the implicate form is the **content** of the culture, which extends into the **consciousness** of each person" (1982, p.185).

This could indeed be considered a general ecological principle: nothing makes sense or has **survival** value without properly defined **connection** and communication with a *specific context*.

0507

COMMUNICATION (Cost of) ⁵⁾

W. S. McCULLOCH stated: "In a communication **code**, the price of a simple **Bit**, or answer to a yes or no question, remains constant, even when we halve the area of ignorance by every question, as we can in playing Twenty Questions. In making **measurements**, the price varies: the **range** of **uncertainty** diminishes inversely as the square root of the number of samples we average" (1974, p.11).

0508

COMMUNICATION (Failure in human) ⁴⁾

G. VICKERS describes three areas in human communication where failure is possible, namely in defining **problems**, in evaluating **programs**, and in securing **cooperation** and concurrence".

He states: "In more static societies the **relations** to be regulated and the **situations** which involve them are usually familiar and are often equally visible to all. In our society, the more numerous **relations** to be regulated combine in subtle and often novel ways and the **situations** which involve them have to be anticipated by techniques of **simulation**, often involving the **combination** of large volumes of **information**. So the task of defining the **problem** is by no means simple. *Ways of seeing the problem become obsolete, no less than ways of solving it...* This need constantly to restructure **problems** makes novel demands on communication".

As to the **evaluation** of **programs**: "The **situation** to which the policy maker attends is not a **datum** but a **construct**, a mental artifact, a collective work of art. It has to be simplified, or it becomes unmanageable: yet, if it is oversimplified, it will be no guide to **action**".

This comment makes clear the reason why our over-simplified or distorted media **messages** are generally so confusing for the public... and even possibly for their own senders.

As to secure **cooperation** and concurrence: "It has to reflect present and future reality; yet if it departs too sharply from the familiar thinking of the past, it will not be sufficiently shared by those for whom it has to provide a common basis for discussion. It has to be not merely discovered but invented, not merely invented but chosen from among several alternative inventions, each a valid but differently selected view. Most difficult of all, it must not obscure the views which it supersedes" (1967, p.63-65).

There is of course much ground for communication failure. This is why *co-participative design* seems necessary to obtain and maintain workable **consensus**.

0509

COMMUNICATION (Human) ⁴⁾

The organized interactive **behavior** among a human group.

Human communication supposes not only the physical transmission of coded **signals**, but moreover the existence of a shared cultural and **semantic code**.

The neglect of this basic condition has been one of the main bones of contention opposing psychologists and social scientists to systemists. In the words of L. THAYER in 1972: "Many spokesmen for **general systems theory** do not address themselves to the **phenomenon** of *human* communication at all. Among those who do, many seem to assume that there are no theoretically significant differences between an electronic **data** system and a human communication system. This terminological confusion, both real and potential, is perhaps even more pervasive among those who identify themselves as human communication scholars or researchers" (1972, p.95-6).

The roots of this problem are to be found basically in what is now frequently called the **1st. Cybernetics**, namely N. WIENER's works and SHANNON & WEAVER's "**Theory of Communication**" (many times erroneously referred to as a **theory of information**, which it is only in a marginal sense). In WIENER's case, **feedback** has been too many times understood as a **control** device of mechanistic character, translatable without much ado to psychology and psychosociology, as for example in B. SKINNER's works. SHANNON & WEAVER's *quantitative mathematical theory of communication*, considers **semantic** and **symbolic** aspects of **communication** only in the most fleeting way. Many of those who naively translated it to human communication obviously ignored G. PASK's, H.von FOERSTER's and D. Mac KAY's basic works, which led to **Cybernetics of the 2d Order**. Various other conceptual currents as for example **autopoiesis** and **organizational closure**, **hypercycles** and **deterministic chaos** are now contributing to put to rest the old purely mechanistic **paradigm** in psychosocial sciences. Unfortunately some scholars do not yet presently know about these new currents.

0510

COMMUNICATION (Layers of) ¹⁾

It is possible to distinguish various layers of communication, from the most basal physical one to the societal one. (In a sense, possibly somewhat metaphoric, any communication layer is societal).

Each layer institutes a higher **level of complexity**. For instance, physical communication leads to integrated atoms and molecules; chemical communication to biochemical complex molecules. Those in turn permit the shaping of complex **living systems** and their internal **coordination** (endocrinal, nervous and perceptive). Eventually nervous and perceptive **coordination** among individuals leads to social **integration**.

A layer of communication at a specific **hierarchical level of complexity** acquires **meaning** only through new specific **constraints**. (PATTEE's **statistical closure** – 1973, p.95-6).

0511

COMMUNICATION (Line of) ^{1) – 4)}

K. BOULDING stated that the lines of communication "... grow at a much slower **rate** than the total **organization**. Hence **organizations** eventually limit their **growth** by the sheer difficulty in getting communications from the "surface" of the **organization**, where it is contact with its **environment**, into the **decision-makers** who are not in direct contact with the **environment**, but have to make **decisions** on base of increasingly less realistic **images** of the world" (1972, p.70-71).

Organizations, and also other kinds of **social systems** react to this problem in two different ways, none of them totally satisfying:

- increasing **hierarchic centralization**, which reduces the general **adaptability** of the system.
- admitting more **decentralization**, which may produce in very large systems a tendency to fractioning and eventual **disintegration**.

The subject is also related, in more general terms, to the subject of **interrelations** between "Growth and Form" (d'ARCY W. THOMPSON – reed.1952).

0512

COMMUNICATION (Meta-) ⁴⁾

The non-conscious **transmission** and **reception** of a **message** embedded in a wider **significative context**.

Any non-rational communication is practically at least partly meta-communication: through religious faith, or art, for instance.

0513

COMMUNICATION (Physical) ⁵⁾

A physical **process** in which a material **transmitter** emits in a well defined **code** some **signals** which can be decoded by an adequate **receiver**.

Voices or sounds, musical or others are transformed into electro-magnetic waves and reconverted to sounds by a telephone or an audio-set.

Thereafter the sounds are received by our hearing system and converted from sound waves to sensations.

Similar **processes** allow for the **transmission** of visual **signals**, for example through a television chain.

These **processes** are completely independent of whatever **meaning** the **signals** may be intended to convey. Here, **coding** is a biunivocal physical **transformation** whose efficiency depends on avoiding perturbing **noises** or compensate them by adequate repetitions (= **redundancy**).

Any type of physical communication needs the following elements: an **emissor** or sender, an **encoder**, a **channel**, a **receiver** and a **decoder**, and... of course, a **source of energy**. Generally the communication **process** must also be monitored in order to ensure its correctness.

0514

COMMUNICATION PROCESS and MEANING ^{3) – 4)}

As stated by F. ROBB: "Communications are **interactions** involving the use of previously formed **meanings** to initiate **actions**, including further **conversations**" (1993, p.1). **Meanings** are socially formed through **conversation** and **consensus**.

ROBB explains how a human group or **organization** forms and stabilizes **meanings** by: "... the **aggregation** and "packaging" of bundles of **concepts** under pantechon **labels** and burying them along with all the other taken-for-granted assumptions in the **meaning set**. This having been done, these topics become forbidden for discussion and become part of the **reflex communication system**"...

A once for all bounded social and/or cultural communication **space** becomes thus defined.

"This shift from the discussion of issues to the embodiment of **concepts** in **automatic communication systems** is very familiar to managers" (p.2). They may however lead to **clanthink** (J. WARFIELD).

D. MacKAY writes: "Claude SHANNON'S measure of selective **information content** was framed explicitly to require no reference to the **meaning** of the **information** selected in **response** to a communication **signal**. The communication process was viewed as a transaction between terminals whose task was confined to the generation and **reproduction** of **symbols**.

"The **understanding** of these **symbols** was declared to be the concern of the communication engineers and the saying went abroad that **Information Theory** had no place for the concept of **meaning**" (1969, p.19)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Of course, the discrepancy is unavoidable when one speaks of "**symbols**" in this **context**, since "**symbols**" is understood either as computable logical signs or as something strictly from the realm of human **knowledge**. It would be better to use here the word "**input**", which is **semantically neutral**.

To make this point still clearer let us use an example. The atmosphere around us is presently densely crowded with a flow of radio and TV waves, beamed by appropriate material **transmitters** as **outputs**, but previously **coded** by men to be transmitted.

Most of these waves are lost, because no material **receiver** collects them. Those which are picked up, become **decoded** as sounds and images only as the **receiver** is switched on. However, still, if nobody stays in the room to listen and to view, sounds and images disperse without transmitting any **meaning**. Thus, we must include that the **meaning** is potential and becomes actualized only by the human **receiver**. Moreover, she or he must know the corresponding **semantic code** or **codes** without which the **message**, even correctly received, remains senseless.

Of course, SHANNON'S theory remains perfectly valid within its own limits, when referring to the **transmission of signals** and their measure as related to the *quantity of information* to be transmitted.

0515

COMMUNICATION SYSTEM (Physical) ⁵⁾

The core of any communication system is a **set** of material devices organized in order to function in a sequential way: A **transmitter**, or sender, a **channel** and a **receiver** (or a multiplicity of **receivers**).

Visible, auditive or electro-magnetic **signals** circulate within the **channel** from **transmitter** to **receiver**, differentiated through the use of some **code**.

The correct **transmission** of the **signals** can be disturbed by some **noise** emitted by an outside **source**, which invades the **channel**.

It should again be stressed that "the *technical* system of communication does not take into account the *meaning* of the **signals** either at the **encoding** (transmitting) or the **decoding** (receiving) end" (O.S. AKHMANOVA, 1960, p.183).

However, communication systems as a whole are used to transmit **messages**, emitted by some sentient or intelligent being after previous **codification** through a **language** that must also be understandable by the **receiver**. In any intelligent communication there is thus at least a double sequential **codification** and, at the **receiver's** end, **decodification**.

In a telephone conversation, for example, three **codes** are successively used: a **language**, the phonation and the electro-magnetic modulation.

0516

COMMUNICATION SYSTEMS (Human) ⁴⁾

L. THAYER states: "For the "**information**" engineer, a "**bit**" of **information** is a "**bit**", regardless of the time of day or the number of times it is used. Not so the **components** of human communication systems. An individual is not the same in one communication system as he is in another... There is always something which is significantly unique about an individual in every communication system in which he participates. The **components** of a human communication system are interdependent in that system in the sense that the only way they can be defined in *that* communication system is in relation to each other... In an "**information**" (read "**data**") system, the **data** are the **message**. In human communication, "**information**" is the product of a human transform of the **data**" (1972, p.111).

At this **meta-level**, every technical aspect of the **transmission of messages** remains basic, but the whole physical **process** is now the bearer of the psycho-socio- semantic **level's** products.

0517

COMMUNICATION THEORY ^{1) - 3) - 5)}

The theory of the **information transmission** under its various aspects.

The theory of communication has been established by C. SHANNON and W. WEAVER (1949). It is frequently referred to as "**theory of information**", which it is only marginally. In effect, what travels from a sender to a **receiver** is a **signal**, which may, or not, convey an understandable **meaning**, when conveniently, or not, coded in a **meaning bearing code**.

The theory states in a general way the conditions for the reliable and correct **transmission** of **data** (or **information** if these **data** are included in an interconnected global system). It includes the study of physical **codes**, **channels**, **transmitters** and also **noises**, that can distort or destroy what is transmitted, and of the conditions needed to make up for these negative **effects**, i.e. the use of **redundancy**. It also establishes ways to organize and quantify **information** for its **transmission**.

The fact that **information** is *organized* explains why **entropy** is proportional to the lack of **information**, as demonstrated by SHANNON. However, the use of the term "**negative entropy**" frequently associated with **information** has been seriously questioned.

Communication theory can, in principle, be applied to any **mode of transmission of information**, be it nervous, visual, by sound, electronic or, in a different sense, **linguistic**.

The basic **elements** of a communication system are: the **transmitter** (i.e. the **encoder** and broadcaster), the **code** itself with its basic units (for example **bits** or **bytes**), the **energy** impulses used, the **transmission** lines or media (**channels**), the **receiver** (i.e. the **decoder**).

In any case, as observed by H.von FOERSTER, Communication theory in its strict sense, is not much else than a simple general theory of communication technology.

0518

COMMUNICATIONAL MODES ⁴⁾

G. BATESON states that rational, logical and verbal communicational modes are merely some particular modes of human communication. Examples of others are: "... play, non-play, fantasy, sacrament, **metaphor**, etc." (1973, p.174) He observes even among the lower mammals "exchange of **signals** which identify certain meaningful **behaviors**" (ibid).

He could easily have added at least social insects and probably some non-vertebrate **colonial** animals like medusae, sponges, etc., if communicational modes are to be identified by the **effect** on some **receiver(s)** of **signals**, meaningful for them, emitted by some **sender(s)**.

Should one admit that communication does not necessarily imply psychism, it could be even be rooted at quite more elemental **levels**: genetic, chemical or physical.

0519

COMMUNICATOR ⁴⁾

Anyone who transmits **information** to other people.

A. LOTKA, taking up an idea also emitted by A. KORZYBSKI (1933, 1950), writes: "Man is the only animal who in any considerable measure bequeaths to his descendants the accumulated wisdom of past generations. **Evolution** in this case proceeds not merely by the slow **process of selection**, but is immensely hastened by the cumulative and continuous growth of a body of **knowledge** exempt from the law of mortality which sets a term on the life of the individual" (1956, p.379)

To a greater or lesser degree, we are all communicators and it is mainly this **function** which shapes society.

From the viewpoint of **evolution**, we could speak of a kind of collective lamarckian heredity of acquired mental characters.

The existence of communicators in non-human systems has not been researched to any great extent, save in ethology. However the presence, at the genetic **level**, for example, of **elements**, specific bearers of the communication **function** seems to be essential to explain

organizational closure and **autopoiesis** in **living systems**. The same question is also latent within the ecological hypothesis of the "**planet system**" ("**Gaia**")

0520

COMMUNITIES (Types of Human)⁴⁾

During its 1998 Conversations, the **Fuschl Group** strongly felt the need to establish clear distinctions between different types of human communities in **history**, in our present time and, possibly, in the future.

This need appeared in connection with the general aim to reach a better **understanding** of the ways toward the instauration of harmonized evolutive human communities, that could avoid through generally participative **design** the tragic political and social disasters of the past and the present.

After an extended debate the following typology of human societies was tentatively established. The typology is evolutive, as the Group understands that there is a progressive (but also at times catastrophically **discontinuous**) **transition** from one type to the next one.

Such an **evolution** seems to be irreversible, but this cannot be guaranteed.

Traditional Community: A **closed, stable system** where the individual's **identity** is determined by a collective **identity** rooted in transmitted myths, **values, norms, and rites**.

Examples are clans and tribes, agrarian villages, religious communities.

This has been the dominant type until it became deeply eroded by the technical and demographic **transformation** of the two last centuries.

Surrogate Community: A **closed, unstable system**, artificially created to attract and satisfy disenfranchised individuals yearning for community through imposed **norms and values**.

Examples are proselitist ideologized **groups**, fundamentalist religious **groups**, religious sects.

The word "artificially" should be qualified. Most communities of this type are founded by charismatic leaders who, somehow, sense the existence in people uprooted from their traditional community, of a deep need to "belong" and are able to respond to it in accordance to their own needs and psychological conditions.

Learning Community: An **open and dynamic system** in which reactive and **proactive** individuals collectively adapt to their **environment**.

Examples are administrative **organizations**, business firms, political parties, scientific research **groups**.

This type of **adaptation** is made of more or less **discontinuous** episodes (for example in business mergers), but are not deeply evolutive.

Evolutionary Learning Community: An **emergent open system** demonstrating **dynamic stability** by adapting with its **environment** and generating sustainable evolutionary pathways.

Until now, such communities are very rare, as they must initially rely on **consensual** collective **self-organization** by a number of individuals who understand how to self-organize (and re-organize) and how to do it as a way to transcendent permanent **transformation** in a necessary evolutive way. (M. BENEDEK & G. CHROUST (Eds), 1998)

→ **Syntony Quest**

0521

COMMUNITY¹⁾

1. A **structure** made of interconnected individuals living in similar **environmental** conditions.

The individual members need not necessarily be all quite identical even if they are all of the same general type. They may very well carry out different **roles** or **functions**.

K. BAUSCH defines community as "A **group** of two or more individuals with a shared identity and a common **purpose** committed to the joint creation of **meaning**" (Glossary- Personal communication)

This is true in ecological communities as well as in human ones. Moreover, **heterogeneous** communities are stabler than **homogeneous** ones, since they possess more **diversity (variety)**.

2. The sixth **emergent level** of **complexity** in J.G. MILLER's **taxonomy of living systems**.

Communities are made of interconnected **organizations** (5th level) and, in turn, combine into structured and organized **societies** (7th level).

0522

COMMUNITY (Epistemic)^{3) - 4)}

A **human communication system** which is extended in **space** and **time**.

This **concept**, proposed by B. HOLZNER (1968) and here adapted from L. THAYER (1972, p.112), is thus explained by this last author: "Those who have been similarly *informed*, who have similar **frames of references**, similar **epistemologies**, similar "reality-testing" procedures, and who thus mutually validate each other's ways of knowing, can be said to be members of the same epistemic community" (Ibid).

Validation is always referred to a prior system of **values, concepts** and **behaviors** accorded within the community through an explicit or implicit **process** of **consensus**, possibly shifting as time goes on.

The crossing by individuals or groups of the **boundaries** of an epistemic community and their intrusion in another one, is generally known as "**transculturation**" and generates in many cases very serious problems of poor communication and intolerance, which may produce violent **conflicts**.

0523

COMMUNITY (Learning)

→ **Communities (Types of human)**

0524

COMMUNITY (Evolutionary learning community)

→ **Communities (Types of human)**

0525

COMMUTATION²⁾

"The **relation** in which **addition** and/or **multiplication** is **symmetrical**. Non commutation is the **relation** in which **addition** and/or **multiplication** is **asymmetrical**" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.33).

In the case when added or multiplied **elements** are not all of the same type and their appearance is serial, the **relation** between them is necessarily non-commutative. On the contrary, in the case of grains of sand accumulating on a dune, or locusts in flight, the **order** of incorporation of the **elements** is irrelevant.

0526

COMPARATOR²⁾

That **part** of a **regulator** that meets the difference between the desired (reference) **input** and the real one.

The **control** unit in the **regulator** needs to be informed of the value of this difference, generally called the "**error**". The **error** triggers a suited **message** of the **controller** to the **effector**.

0527

COMPARTMENTATION²⁾

"Partial **closure** from the **environment** which is necessary for multiorder **feedback** to develop between the **components** within (the system)" (G.H. FAIRLOUGH, 1988, p.408).

The notion has been introduced by M. EIGEN and P. SCHUSTER in "The **Hypercycle**" (1979), with biological examples.

"By analogy, we can view compartmentation as critical to the **evolution** of self-organizing adaptive social systems" (FAIRLOUGH, p.408).

Compartmentation is hypothesised to lead to the shaping of a **boundary** by way of the progressive self-organization of **cyclic** and **hypercyclic** **feedbacks**. The final result should be complete **organizational closure** and **autopoiesis** (see "The Hypercycle", p.86).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Compartmentation could start with the appearance of **dissymmetries** in some specific surroundings. See Hans KUHN on this topic (1976).

0528

COMPATIBILITY¹⁾ – 4

Indispensable non-contradiction in the **behavior** of **elements** and/or **subsystems** in a **complex system**.

Non-compatible **elements** are those whose **behavior** produces **outputs** which are destructive for other **elements**.

What may be contradictory in the **behavior** of the **elements**, is a result of the **rules** which command such **behavior**. Some of J. CONWAY's **games of life** are **models** of self-destructive or self-blocking systems, due to **interactions** of incompatible **rules**.

No **complex system** allows for a long time the presence of **elements** or **subsystems** not being in harmony with its basic nature, as defined in its **central control subsystem**, which imposes its **organizational closure**.

Non-compatible **elements** are quickly identified, isolated and rejected as for example in the immune reaction or in case of exclusion of the human group. Racial, religious or cultural intolerance are probably kinds of social immune reactions, which makes them very difficult to avoid.

A specially interesting subject for research in G.S.T. would be a general inquiry in the ways to overcome or reduce **rejection reactions** when nocive.

0529

COMPETENCE⁴⁾

"The *qualification* to implement an **activity**" (G.de ZEEUW, 1992, p.1076).

de ZEEUW adds the following, in a descriptive way: "...using the **activities** or **resources** of other actors when necessary but without making such **activities** impossible or dominating such **resources**, and to continue implementing it even given unexpected and unpredicted **variations** in such activities and **resources**, that is *skillfully*" (Ibid).

Competence is thus connected with **adaptability** and **efficiency** in **networks**, mainly through the ability to order and compatibilize **processes**.

According to de ZEEUW, the degree of competence depends also on the use of a better **observational language**.

N. CHOMSKY uses the concept in **linguistics** to express the potential ability of a **language** user to understand and form an immense number of sentences, which she/he has in many cases never heard or used before.

In synthesis, competence is a potential for **action**.

0530

COMPETENCE (Communicative)⁴⁾

In a **heterarchical organization**, the capacity of any **element** to share his/her (and its, if the concept can be somehow translated to natural or artificial non-human systems) **knowledge**, experience, **information**, etc... to any other **element** of the **organization**.

J.A. JOHANNESSEN describes the conditions for communicative competence, as resumed hereafter:

- Listeners must be attentive, without interrupting
- **Knowledge** is in the **dialogue** and not with the single individual
- Recognition must be reciprocal and the **dialogue** free of **domain dominance**
- Only the power of rationality is to be used
- Principles of **complementarity** and **self-organization** are the bases of **dialogue**
- **Dialogue** must be constantly validated
- Every explanation is personal and fragmentary
- **Knowledge** is obtained through a shared **communication process**
- The minimum unit in **communication** is the "triad": **action** - **reaction** - resultant
- Pathology of **communication** should be clearly understood: self-contradiction, inconsistencies, shifting of **types (categories)**, obscurities, etc...
- An explicit evaluation of the surrounding conditions of **communication** is needed
- Participants establish a **metarule** for their **communication**
- **Dialogue** is based on **synthesis**, with the **problem** definition phase emphasized
- Premises and suppositions must always be explicit
- It is not possible to impose **linear** thinking upon **nonlinear** reality (1991, p.49-50).

These guidelines have much in common with J. WARFIELD's **Generic Design**.

0531

COMPETITION²⁾ – 4)

A mutually limiting **interaction** between two or more systems or **subsystems**.

R.L. ACKOFF and F.E. EMERY, quoting KATZ and SHANK state: "... competition is **conflict according to rules** and hence is *constrained conflict*" (1972, p.199).

"Repulsive **interaction** between a pair of **functions** decreasing the **probability** that they follow each other in **space** or **time**" (R. FIVAZ, 1996, p. 143)

Competition is basically caused by the scarcity of some **resource** needed by the various intervening systems, as for example **energy**, **space**, raw materials and **information**.

Competition leads easily to open aggression and **conflict**, but may also induce a **negotiation process** which, in turn, may be conducive to the establishment of a **regulator** or **control** device accepted by the competing systems.

In case of such agreement or enforced mutual limitation, the **regulator** becomes a basic **element** of a higher level of **organization**. Competition for **resources** then becomes a regulated **zero-sum game** between the systems or **subsystems**.

The cost of **regulation** is generally quite inferior to the cost of unbridled competition.

0532

COMPETITIVE ASYMMETRY²⁾ – 4)

Competition is usually asymmetric, which means that one (or some) of the competing **elements** or systems has an initial advantage or acquires it, obtaining thus a larger share of the available **resources**.

The study of competitive asymmetry led to a quite more complex view of the **evolution** of **ecosystems**, relativizing the concept of **climax**. It could also probably be applied to the **evolution** of oligopolies and monopolies in economy, and in balances of power in politics.

0533

COMPETITIVE EXCLUSION PRINCIPLE²⁾ – 5)

"One of two **populations** of self-duplicating **organisms**, if permitted to expand with **Malthusian growth** without selective **control**, will drive the other out of the realm" (H. ODUM, 1983, p.53).

H. ODUM, who enounces the principle, writes: "The one with the slightly better reproductive **performance** is **self-amplifying** and the discrepancy between the two stocks increases. This is a well-established **phenomenon** in laboratory experimentation where other **controls** are removed... This tendency for **run-away** competitive exclusion of one part of a **network** is a fearsome ever present danger against which all surviving systems must be protected by organizing influences" (Ibid).

In other words, the more **complex** a **supersystem**, the more dynamically stable are the participant systems. Eliminating seemingly competing systems is thus dangerous, specially because the remaining system can very well run away toward self-destruction through a **positive feedback** which encounters no more resistance.

A similar competitive exclusion **mechanism** has been proposed by ethologists as expressed by J.N. LOCKE: "If a brain **mechanism** has limited **capacity**, it may be preempted by early stimulation and rendered insensitive to later stimulation of a different type" (1994, p.441).

This explains for instance the life predominance of the mother **language** and the subsequent difficulties in learning other **languages**.

A similar idea had already been enounced by P. COLINVAUX in 1973 (p.337): "Stable populations of two or more species cannot continuously occupy the same niche". And even earlier, in 1934, the russian biologist G.F. GAUSE had formulated it (becoming known as GAUSE's Principle). By experiences on two different species of *Paramecium* put in **competition**, GAUSE showed that one of the species always finally died out. (1934)

While in more recent experiences with *Drosophila* seemed to infirm the principle in some cases, it remains however of very general validity.

Within some well specified limits, it may also prove to be applicable more generally to social **situations**. for example e-mail could conceivably eliminate finally common postal written or typed mail. Such extensions of the principle should however be handled with care.

0534

COMPILER⁵⁾

"A computer **program** which reads a computer **program** in a higher **level language**, usually in the one a human programmer uses to state his **problem algorithmically**, and translates it into the machine **language** of a particular computer" (K. KRIPPENDORFF, 1986, p.13).

0535

COMPLEMENTARITY²⁾

A way of **organization** whose "governing **relation** is **symmetrical dependence**" (FEIBLEMAN, J.& FRIEND, J.W., 1969, p.36).

This **organization mode** is related to **models of integrated systems**, as **parts** can hardly survive their splitting off. Complementarity implies that **parts** of different identities fit usefully, or at least satisfactorily with each other.

Complementarity is typical of very complex and **heterogeneous** systems, in which numerous **functions** and **structures** can operate and maintain themselves only by **cooperation**.

Complementarity is quite obvious, for example in James G. MILLER's description of the **20 critical subsystems in living systems**.

As a **concept**, complementarity carries some semantic **ambiguity**. According to J.A. GOGUEN and F.J. VARELA: "Our usual way of thinking about pairs of descriptive notions is biased in the direction of regarding them as mutual negotiations of the general form not-A/A. It is the case, however, that many of the most important such pairs operate by mutual specifications, that is, are complementary. We mention in particular, **content/form**; **semantics/syntax**; **autonomy/control**; **net/tree**; **minimal-model/behavior**; **simultaneous/sequential** and **environment/system**" (1979, p.40).

Others complementarities are: being/ becoming; levogyre/dextrogyre (in molecules and crystals); **stability** and **change**. Moreover, complementarity is not merely **binary**: many different **processes** and/or **functions** enter into intricate **associations** in **complex systems**.

0536

COMPLEMENTARITY PRINCIPLE (BOHR)^{2) - 3) - 5)}

In the first years of 20th Century, physicists came to recognize a logical contradiction between two basic aspects in micro-physics:

"1- "PLANCK- in order to derive the empirical laws of black body radiation- had to assume that electromagnetic radiation is exchanged in discrete units, apparently in contradiction with the classical theory, which considered electromagnetism to be carried by continuous **fields** of waves.

"This concept was elaborated by EINSTEIN, who introduced the concept of a photon as a discrete, particle-like unit of electromagnetic radiation.

"2- Shortly thereafter, an opposite **phenomenon** was observed: electrons, which were considered to be particles, appeared to undergo interference, which is typical of **waves**. This double phenomenon... was called the **wave-particle duality**.

"The statement that something is at the same time a particle, hence discrete or **discontinuous**, and a wave, hence **continuous**, is a logical contradiction.

"The prevailing attitude toward this problem (known as the Copenhagen interpretation) was formulated most prominently by BOHR. According to BOHR, we cannot know physical reality as it is, independently of ourselves. We can only make certain **representations** of our **interactions** with physical systems. These **representations** are necessarily formulated in the **language** of classical physics. In the case of macroscopic **phenomena**, however, there is no complete and consistent classical **representation**: There are only partial **representations**, such as the wave **representation** and the particle **representation**, which are complementary. Complementarity means that the **representations** are mutually exclusive yet they are jointly necessary (they complement each other) for an exhaustive description of the physical **phenomenon**" (F. HEYLIGHEN, 1990b, p.479).

This problem in the **perception** of our **environment** (already considered by some philosophers – Western and Eastern) only appeared when our research started to interfere significantly with the **phenomena** we are studying, i.e. when the **observation** act give itself on the same **scale** or **level** of the **phenomena**. It shattered our belief in our capacity to reach **ontological** reality and it made us understand that our **interactions** with our **environment**

are not neutral. This **understanding** propagated itself slowly to every scientific research and became part of the foundations of **constructivism**.

Another consequence has been that **models** in micro-physics, astrophysics and generally every discipline widely separated from our common macroscopic **scale** of **perceptions** are becoming completely abstract and untranslatable in common sense **concepts**.

In J. HORGAN's words BOHR "... held that wave-particle duality is a **paradox** that cannot be resolved. BOHR also ruled out the possibility that the probabilistic **behavior** of quantum systems was actually the result of underlying **deterministic** hidden **variables**. Reality was unknowable because it was intrinsically undefined, BOHR insisted".

HORGAN pursues: "In 1952 BOHM defied BOHR's prohibition against hidden-**variable** explanations".

In fact, he reintroduced L.de BROGLIE concept of the permanent existence of particles, guided by a pilot wave. According to HORGAN, BOHM'S introduction of a new force, the quantum potential "was **causal**, or **deterministic**. Particles always had a distinct position and velocity, but any effort to measure these properties precisely would destroy **information** about them by physically altering the pilot wave. BOHM gave the **uncertainty principle** a purely physical rather than metaphysical **meaning**. BOHR had interpreted the **uncertainty principle**, BOHM explained, as meaning "not that there is **uncertainty**, but that there is an inherent **ambiguity**" in a quantum system".

BOHM's interpretation did however revived the EINSTEIN-PODOLSKY-ROSEN paradox, which HORGAN states as follows: "According to the standard **model** of quantum mechanics, neither of two particles (that spring from a common source and fly in opposite directions) has a definite position or momentum before it is measured; but by measuring the momentum of one particle, the physicist instantaneously forces the other particle to assume a fixed position – even if it is on the other side of the Galaxy".

EINSTEIN derided "...this effect as "spooky action at a distance"... that violated both common sense and the theory of relativity, which prohibits the propagation of effects faster than the speed of light".

This "spooky action at a distance" was however experimentally demonstrated by A. ASPECT and his Paris-South University group in 1982, following a mathematical proof by BELL, in 1964. Moreover, "...The reason that **nonlocality** does not violate the theory of relativity is that one cannot exploit it to transmit **information** faster than light or instantaneously".(1993, p.40-41).

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

This posits the general **irreversibility** of physical **phenomena** and could indicate the necessity of a still more global understanding, including relativity, quantum mechanics and **thermodynamics**.

All in all, BOHM's **nonlocality** as well as BOHR's **complementarity** and HEISENBERG's **indeterminacy** (or **uncertainty** ?) **principle** seems to thrust a shadow of doubt over our most fundamental **concepts** "...as **space** and **time** (which) may be merely explicate manifestations of some "nonlocal, deeper implicate order" according to BOHM" (Ibid., p.452).

Deterministic chaos, for instance, seems to lead to quite similar doubts about the deeper **meaning** of our mental **frames**. No systemic **ontology** can avoid these doubts about our possibility to attain true fundamental **knowledge** about reality.

0537

COMPLETION FROM WITHOUT Principle³⁾

"The ultimate inadequacy of any **control language** to perform its task can be remedied by the technique of inserting a **black box** in the **control circuit**" (After S. BEER, 1971, p.81).

The ultimate inadequacy referred to by BEER is, as he himself states, a result from **GÖDEL's Incompleteness Theorem**. His principle is based on the idea that: "The function of the **back box** is precisely to invoke the **decisions** of a higher **language**, which of course cannot by definition be expressed in terms of the **control language**, to repair the deficiencies of the original **decision-making** machine... The undecidable **language** is to be keyed in" to the real life it seeks to describe by an inherently indefinable **black box**" (Ibid).

This should be compared with J.van GIGCH's concept of **metasystem** and its use for "**decision making** about **decision making**" (1986).

0538

COMPLEX PHENOMENON²⁾

P. CORNING describes as follows the **attributes** of a complex phenomenon:

1. A complex phenomenon consists of many **parts** (or items, of units, or attributes)
2. There are many **relationships/interactions** among the **parts**
3. The parts produce combined **effects (synergies)** that are not easily predicted and may often be novel, unexpected, even surprising. (1998b, p.30)

0539

COMPLEX (Supremacy of the)^{1) - 2)}

H. SABELLI opposes in a dialectic way what he calls the "**priority of the simple**" and the "**supremacy of the complex**" (1994).

He means therewith that any complex **process** dominates and controls more simple ones, *but* that their existence is conditioned by the prior existence of the simpler ones. For example, the physical **processes** of the inanimate world are simpler than the biological ones, but, in an **organism** the physical **components** are organized by the physiological ones. SABELLI states: "It is thus, in principle possible to study the superior **processes** through the consideration of the **organization** of the simpler ones which constitutes them; reciprocally, to understand how the inferior ones are organized, it is necessary to consider the superior ones, which control them" (Ibid).

In this way, the analytic and the synthetic viewpoints become complementary and reciprocally needed.

0540

COMPLEX SYSTEM¹⁾

"A system made up of a large number of **parts**, that interact in a non simple way." (H. SIMON, 1965, p.63).

H. SIMON comments this informal definition as follows: "In such systems, the **whole** is more than the sum of the **parts**, not in an ultimate, metaphysical sense, but in the important pragmatic sense that, given the properties of the **parts** and the laws of their **interaction**, it is not a trivial matter to infer the properties of the **whole**. In the face of **complexity**, an in-principle **reductionist** may be at the same time a pragmatic **holist**" (p.63).

One should add that the complex system is altogether in some sense *less* than the sum of its **parts**, since these always abandon some of their properties, as they become inhibited by some **constraints** resulting of the global or some particular **interactions**.

The complex system is thus not merely *complicated*, as these **constraints** are generally of various kinds and *reciprocally constraining*. **Complexity** is organized and the complex system presents **organizational closure**.

Of course, from a different viewpoint, complexity is in the eye of the **observer**, as explained by R. ROSEN: "We are going to define a complex system as one with which we can interact effectively in many different kinds of ways, each requiring a different mode of **description**" (1977, p.229).

J.L. LEMOIGNE proposes the following nine characteristics each one of which increases the **complexity** of a system: 1) to be identifiable; 2) to be active; 3) to be **regulated**; 4) to be informed about its own **behavior**; 5) to be able to decide its own **behavior**; 6) to be endowed with **memory**; 7) to be able to coordinate its **behavioral decisions**; 8) to be able to imagine or conceive new possible **decisions** and 9) to be able to finalize itself (1990).

0541

COMPLEXIFICATION^{1) -4)}

Growing diversification in a system's **complexity**.

To become more complex, a system needs to enhance its internal **variety**. This is possible only by obtaining a richer internal combinatorics.

This can be obtained only by an increase of the number of **elements**, allowing for a factorial **growth** of possible combinations (if no new **constraints** are introduced).

It is debatable if all classes of systems are able to do this.

Only complex **social systems**, when still endowed with many "open ends", can conceivably become more complex, because they are more **open** and less integrated than biological systems for example, which are strictly submitted to **organizational closure**. In social systems, writes P.M. ALLEN "Complexification feeds on itself because it creates new **situations** and dimensions... **Fluctuations**, both in normal **behavior** in the real world, and in the mental maps of actors, explore **situations** which are richer than the reduced **description** of the world given by any solution of the **model**. These explorations can lead to **amplification** by the **non-linearities** in the system and hence to its structural **evolution**" (1982, p.59).

0542

COMPLEXITY¹⁾

(From Latin: complexus, i.e. containing)

Some definitions

According to common dictionaries

G. KLIR quotes Webster's Third International Dictionary, according to which complexity: "is the quality of being complex" i.e.:

"- having many varied **interrelated parts, patterns**, or **elements** and consequently hard to understand fully", or

"- marked by an involvement of many **parts**, aspects, details, notions, and necessitating earnest study or examination to understand or cope with" (1993, p.40).

For the American Heritage Dictionary, complexity implies: "...interconnected or interwoven **parts**... involved and intricate, as in **structure**". And: "**Complex** often implies many varying **parts**. **Intricate** refers to a **pattern** of intertwining **parts** that is difficult to follow. **Involved** stresses confusion arising from the commingling of **parts** and the consequent difficulty of separating them". Moreover "**Tangled** strongly emphasizes the **random** twisting of many **parts**".

G. KLAUS and H. LIEBSCHER's german *Wörterbuch der Kybernetik* gives a more formal definition: "The complexity *K* of a system is directly proportional to the number *n* of its **elements**, the number *z* of the possible **states** of these **elements** and the number *k* of **couplings** between the **elements**" (1976, p.314).

French and Spanish common dictionaries are much less precise and do not offer specific insights.

H. SIMON's views

K. BAUSCH has given a most general definition: "A systemic characteristic that stands for a large number of densely connected **parts** and multiple **levels** of **embeddedness** and **entanglement**"

This definition can easily accommodate for example stellar-planetary systems or **ecosystems**

1. Systems with numerous **components** may be considered complex. Thus the *cardinality* of a **set** can be used as a measure of complexity.
2. Systems with much *interdependence* between **components** are generally considered more complex than others with less *interdependence*.

3. **Undecidable** systems (GÖDEL, TURING) can be considered as complex in comparison to **deterministic** ones.

4. Complexity of systems can be measured by their **information** content in the sense of SHANNON and WEAVER.

5. In this context, "informational complexity" can be defined by the number of **parameters** or **symbols** needed for their definition.

6. "Computational complexity" refers to the number of calculus steps needed to resolve problems corresponding to a specific **class** (1977, p.507).

Some French views

1) "Complexity of a system depends on two factors:

the number of **elements** that constitutes it and, the number of **interrelations** among them" (J.L. LEMOIGNE – 1990a, p.91).

This definition is merely quantitative. It does not say anything about the *nature* of the **interrelations**.

2) According to E. MORIN, complexity implies **recursivity** and can be characterized by "a tangle of myriads of **inter-retro-actions**" (1984).

Here, the **structural** and **functional** nature of complexity is emphasized.

3) J.L. VULLIERME insists on the **hierarchical** character of complexity, that implies: "... a plurality of logical **levels**, **interdependent** but irreducible to each other" (1990, p.147).

Complexity is also in the eye of the **observer**.

4) B.de HENNIN defines complexity as: "the expression and manifestation of the potential and actual **behavior** of a system that an **observer** represents in a **model**".

Such a **model**: "...expresses, includes and connects what is probable and what is certain, what is organized and what is dubious" (1993, p.1492).

This author enumerates a series of conditions:

- The need for the system to be able to communicate
- The interactive **behavior** between the system and its **environment** (translatable into **digital** as well as **analogic information**)
- The presence of an **observer** interacting with the system
- The existence of a specific project of the **observer**
- The scientific rationality implicit in the project
- An **epistemology** in correspondance with the **model**

5) J.L. LEMOIGNE writes that it may be "... a property of the presently available **representation** of the system" (1990 b, p.109).

6) R. VALLEE states that it "... depends on the grain of **observation** and on the selected **resolution level**" (1990, p.240).

Many definitions of complexity have thus been proposed. They differ due to the very variable **viewpoints** of their proponents. It does not seem appropriate to exclude any: each contributes some specific angle, useful for the global understanding of what we mean by complexity.

0543

COMPLEXITY: A broader view ¹⁾

"The name we are giving to the condition of human beings, **objects**, **phenomena**, **process**, **concepts** and feelings because:

- a) they are difficult to understand or explain
- b) their **causes**, **effects** or **structure** are unknown
- c) they require either a great deal of **information**, **time** or **energy** to be described or managed or a huge coordinated effort on the part of the persons, equipment and machinery
- d) they are subject to a **variety** of **perceptions**, interpretations, reactions and applications that are often contradictory or disconcerting
- e) they produce **effects** that are simultaneously desirable and undesirable (or difficult to **control**)
- f) their **behaviour**, depending on the case, may be **unpredictable**, relatively **unpredictable**, extremely variable or "counterintuitive" (F. SAEZ VACAS, 1990, p.83).

Complexity is rather different from **complication**.

The latter can be simplified more or less easily by **classification**, **reduction** to some few types, as for example in MENDELEEV's periodic table of chemical elements.

Complication may merely be an aspect of complexity.

The periodic **classification** is a mere *consequence* of the complexity of **interactions** at the atomic and nuclear **level**.

The contrary of complexity is not simplicity: J.L. LEMOIGNE even proposes the neologism "implex" to characterize a unit that cannot anymore be decomposed, at least at the **level** of the intended research. For example, individuals would be "implexes" in **social systems**, irrespective of their biological complexity.

As stated by G. MIDGLEY, we may distinguish natural world complexity, social world complexity and internal world complexity. The first two ones are necessarily and selectively filtered by the third one. For this reason, according to MIDGLEY: "... it is the explicit **emergence** of **ontological** complexity that is the real challenge facing us" (1992, p.154). In the same vein, W. KARGL observes that a good systemic **understanding** should not aim "...at reducing complexity between system and **environment**, but seek to (discover) **order**, regularity and **invariance**" (1991, p.582).

Such a view is further developed by W.R. REEVES: "Complexity... is a **concept**... used to measure... the relative ratios of the following **semantic pairs**: **order** and **disorder**; confirmation and novelty; **predictability** and **unpredictability**; **redundancy** and **variety**; **signal** and **noise**; **constraint** and **chance**; **differentiation** and **undifferentiation**; **symmetry** and **symmetry breaking**; and **negentropy** and **entropy**" (1992, p.1101).

On the other hand, the condition described by F. SAEZ VACAS is also proper to **living systems** in general, to **ecosystems** (and even many physical systems, as for example, the solar system or the geosphere), societies, animal as well as human, small **organizations** as well as great corporations or nations, **men-machine systems**, and **brains** (of men and animals).

Besides, we already understand some general characteristics of **complex systems**, as for example:

- they are **multi-functional**: different **parts** attend simultaneously different needs. However there are **coordination** devices, which help to maintain **coherence**, strongly in individual systems (like a living being, as a **whole**) or loosely as in social **groups** of any kind.
- they maintain a relatively permanent **identity** during a more or less extended period of **time** (**entitiation**, **organizational closure** in individuals – some basic **templates** or **patterns** in social **groups**).
- they have an **adaptation capacity** in the case of individuals, or of **evolution** in the case of **groups**

It is possible to study complexity from **bottom up** or from **top down**, but the main subject must always be global **coherence** and the **interconnecting** devices which maintain it.

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

Of course, as stated by R. VALLEE: "...it is difficult to speak of complexity in an absolute form and it seems more sensible to contemplate a perceived complexity, depending of the **observer** viewpoint, considering complexity as a **relation** between the observing system and the observed one" (1990, p.50).

In a quite similar way L. LÖFGREN introduces a d-complexity (**description**) and an i-complexity (interpretation), both obviously superposed by our own **level of knowledge** on the supposedly complex **situation** or system considered. (1977).

Here, **information** becomes a measure of complexity, as stated by H.T. ODUM (1983, p.169).

Thereupon we should still add a **modelization** complexity, due to the interferences of our mental and computational tools within the **representation** (for our specific ends) of the system or **situation**.

Viewed from another angle, we may say that complexity begins with **nonlinearity** and with a multiplicity of initial **situations** in various **parts** of the entity under study.

According to E. LASZLO: "On higher **levels** the amount of complexity that can be developed in a system is greater than on lower ones due to the greater diversity and richness of the **components** and **subsystems**" (1992, p.244).

This is related to the progressive build-up of **hypercycles**, which results of the appearance of potentially complementary **elements** in a given **level** and within a given **environment**.

This in turn is consonant with H. SIMON statement that: "Complexity frequently takes the form of **hierarchy**" (1965, p.64). In his terms, there is an "architecture of complexity".

Complexity cannot easily (if at all) be measured arithmetically, probably because it is **structural and functional**. It seems to be a geometrical and **topological** property of **emerging** systems becoming organized on higher **levels**. Thus, two or more systems of the same type could have somewhat different characteristics (for example, fossil ammonites), but be *at the same level* of complexity.

Complexity is not merely statistical **diversity**. In this case, what we observe is merely absence of some coherent **order**, not complexity. Of course, in some cases a very complex *explanation* could possibly be reached, but merely relative to not coherent **diversity**.

Increasing complexity in systems seems to be related to four different but somehow connected evolutive **processes**.

The first one is **dissipative structuration**, which starts to occur when a system is pushed through increasing **fluctuations** far from its **equilibrium level**, toward an **instability threshold**. This is the result of increasing **energy** intakes, excessive for the system as it is organized at the moment. This process must be compensated by a corresponding increase of

entropy production. It may lead to the destruction of the system or to the **emergence** of a new system at a higher **level of structural and functional organization**. Such a system would then stabilize at a corresponding higher minimal **level of entropy production**.

Increasing complexity also implies more numerous and intricate **relations** between more **elements**, i.e. the appearance of a new **level of sociality**, once the critical **threshold** has been crossed. This may correspond with an "increased computational ability" (N. PACKARD). There seem to exist a critical **population density of elements** of a same or of complementary **classes** leading to a kind of **implosion** provoked by a considerable **multiplication** in a limited or shrinking **space**. This changes the individual **behavior of elements** through more numerous, frequent and strong **interrelations**. This in turn, leads to a more and more organized new collective **behavior**, i.e. to the appearance of a new **social system** on a higher **level of complexity**.

Such a system obtains a higher degree of **control** upon extended surroundings, leading to more **stability, productivity and survival time**. Ants societies and beehives, as well as presently expanding human societies are examples.

It should be noted that more **control** on the **environment** means more capacity to obtain **energy inputs**, which leads us back to PRIGOGINE's **thermodynamics of irreversible systems far from equilibrium**.

The third interesting **process** is **criticality**, which seems to be related to "would be" systems. In cases of **avalanches** and other critical **threshold phenomena** of this type, no higher **level of organization** sets in, possibly because all **elements** are of the same kind, or because **energy** is uselessly and prematurely dissipated in a non-structuring way. **Colonial organisms** that alternately **aggregate** and **disaggregate**, as for example the well known **Dictyostelium discoideum**, or sponges, or locust swarms, seem to be a limit case.

The fourth intervening **process** is **semi-deterministic chaotic behavior**, which results from multiple **simultaneous local events** within any intricate **network of elements**. At any precise moment the non-instantaneous and uneven **propagation of effects** allows for a limited and temporary leeway of **indeterminism** anywhere in the **network**, while its *global behavior* remains generally coherent. This makes the systems **behavior** always somewhat unpredictable.

J.L. LEMOIGNE considers that such a basic **unpredictability** is in fact the hallmark of complexity (1990, p.304).

At the most general **level**, complexity could be a cosmic innovative **transformation** toward a more efficient **energy dissipation** and **entropy production process**, compensated by higher global **levels of organization**. Such a view

was introduced by A. LOTKA in 1924 as the ecological **concept** of the "**world engine**", according to which **energy** is most efficiently used in "cascades" throughout the global **ecosystem**. (1956, p.331).

D.L. HARRIS, quoting A.B. CAMBEL (1993), states: "CAMBEL establishes and names three **categories**: the first is "**static complexity**", to include **purpose** and **function** as well as **size** and **configuration**. The second is "**embedded complexity**", consisting of **structure** and including composition and makeup. The third is "dynamic complexity" – a **category** to include various types of **dynamics**. Building upon the **categories**, CAMBEL then constructs fifteen **heuristic** statements, presented here in somewhat abridged form:

"1. Complexity may be found in natural and man-made systems, including social **structures**.

"2. Large and small **components** can live cooperatively in the same complex **dynamical system**.

"3. Physical shape may be regular or irregular.

"4. In general, the larger the number of systems **parts** the more likely the occurrence of complexity.

"5. Both **energy-conserving** and **energy-dissipating** systems can be subject to complexity.

"6. The system is neither completely **deterministic** nor completely **random**, exhibiting both characteristics.

"7. Causes and effects of system **events** are not proportional.

"8. **Parts** of complex systems are linked and affect one another in a **synergistic** manner.

"9. There is **positive** or **negative feedback**.

"10. The complexity **level** depends on the character of the system, its **environment**, and the nature of the **inter-action** between them.

"11. Complex systems can exchange **matter, energy and information** with their surroundings.

"12. Complex systems tend to undergo **irreversible processes**.

"13. Complex systems are dynamic and **not in equilibrium**; they may pursue a moving target.

"14. Complex systems frequently undergo sudden **changes**, suggesting that the **functional relations** that represent them are not **differentiable**.

"15. **Paradoxes** exist, such as organic and inorganic bodies in cohabitation; fast and slow **events**, etc." (1994, p.73).

0544

COMPLEXITY (Accumulative)^{2,4)}

C. HASKINS has observed that complexity in living beings and in insects societies grows out of **accumulation** (1946). In a way, this was already a basic tenet of E. HAECKEL's views of **evolution** with his fundamental biogenetic law: "**Ontogenesis**

recapitulates **phylogenesis**". **Evolution** does not start at any time from scratch: it results from adding new and not contradictory characters to those already in existence. This means that complexity self-constructs from **level** to level. According to Haskins each higher social level of **structures** results of a more or less similar **pattern**. Social forms imply specific types of **interactions** among reciprocally compatible individuals. And once initiated, they tend necessarily to develop coherently (i.e. in a non-contradictory and functional way)

HASKINS considers that human social world similarly tends toward higher degrees of complexity and that this can be seen specially through the cultural evolution of human societies from simpler **forms** toward more and more differentiated and coherently organized ones.

→ **Cross-level research; Priority of the simple; Recursivity; Supremacy of the complex; Zero System**

0545

COMPLEXITY (Algorithmic)²⁾

R. RUTHEN writes: "Some of the best ideas for defining and measuring complexity emerged from the work of Claude E. SHANNON, Andrei N. KOLMOGOROV and Gregory J. CHAITIN during the 1950s and 1960s. They proposed that the degree of complexity is related to the size of the smallest **description** of a system's **behavior**. This theory led to a proposed technique for measuring the so-called **algorithmic complexity** of a **process**. In theory, the complexity of two systems could be compared by writing two computers **programs** that are the shortest capable of reproducing the original **data**... The **program** with the fewer instructions would describe the less complex system" (1993, p.114).

The same idea was expressed by V.G. DROZIN: "The complexity of a system can also be expressed by the number of steps of a prescription or **algorithm** needed to assemble the **whole** from its **parts**.... Indeed, the greater the **variety** of **parts** and their number,... the longer will be the algorithm needed for its assembly".

And still: "(The) expressions of complexity of a system are reducible to the number of its non-interchangeable **states** and can be linked to the **negentropy** content of the system" (1975, p.9).

An original view is R.V. JENSEN's, who states: "The theory of algorithmic complexity reveals that the origin of **chaotic behavior** in **nonlinear dynamical systems** and perhaps in nature itself lie in the **randomness** of almost all real numbers" (1987, p.178).

→ **Numbers (rime)**

However, if a system is very complex (or if the **level** of our analysis is high) we are led to **algorithmic incompressibility**, or in other cases, to the practical impossibility to compute because we would (in accordance with **BREMERMAN'S limit**) "literally have to wait from now to eternity to find out the results" (Ibid).

0546

COMPLEXITY (Algorithmic)

→ **Algorithmic complexity**

0547

COMPLEXITY (Algorithmically incompressible)^{2) - 3)}

J. BARROW states "There exist complex **phenomena** whose **evolution** through **time** cannot be represented by any abbreviated formula, so that the most succinct **representation** of their **information** content is nothing less than their complete **history**" (1991, p.60).

In such cases, no abbreviated statements of **invariance** are possible.

0548

COMPLEXITY as perceived^{1) - 3)}

As observed by R. ESPEJO: "Individuals only see 'sides of a **situation**', never the whole of it; indeed, there is no **viewpoint** that can capture in full the **variety** of a **situation**. Different **viewpoints** 'see' different **chunks** of **variety**, and no **viewpoint** can see the full **variety**, not least because human **activities** are constantly being created and recreated by the people participating in them" (1988, p.139). And: "Outcomes are related to **patterns** in **time** (i.e. **behaviours**), and the complexity of the **situation** is defined by the number of non-equivalent outcomes recognized by the **viewpoint** in the **situation**" (p.140).

In ESPEJO's words, **viewpoints** act as "**cognitive constraints**".

Perceived complexity is thus merely an aspect of total complexity, which could be equated with the **variety** in the system or **situation**. Moreover, it is always a transitional reflection of the same, because all **situations** and systems are permanently changing. In ESPEJO's words: "... perceiving complexity has a **time** dimension, and... the history of **viewpoints** is essential to work out the outcomes of a **situation**, that is, to work out its complexity" (p.144).

This implies that:

- a broader **range** of **viewpoints** gives a deeper **understanding** of the system or **situation**, as observed in different ways by J. WARFIELD (**Nominal Group Technique**), B. BANATHY and the FUSCHL Group (**Co-participative design**) or J. JOHANNESSEN (**Heterarchy**).

- a satisfying **consensus** between **viewpoints** gives a more accurate global view of **complex systems** or **situations**.
- frequent reviews of the different **viewpoints** allow for a progressive deepening of **understanding** of complexity.

0549

COMPLEXITY (BOULDING's 8 levels of)¹⁾

K. BOULDING proposed a "...**hierarchy** of complexity, roughly corresponding to the complexity of the "individuals" of the various empirical fields" (1956, p.14-15).

The levels are as follows:

- 1 - The level of the static **structure**, or frameworks, "whose accurate **description**... is the beginning of organized theoretical **knowledge** in almost any field"
2. - The level of clockworks, "... simple **dynamic systems** with predetermined, necessary motions... Such a system may reach a position of **stationary equilibrium**, or it may not - there are plenty of examples of explosive **dynamic systems**"
3. - The level of the **control mechanism** or **cybernetic system** in which "... the **transmission** and interpretation of **information** is an essential **part** of the system... The **homeostasis model**... is an example of a **cybernetic mechanism**"
4. - The level of the "**open system**" or self-maintaining **structure**. "This is the level at which life begins to differentiate itself from not-life. However "Something like an **open system** exists, of course, even in physico-chemical **equilibrium** systems", wherein "**structures** maintain themselves in the midst of a **throughput** of electrons, molecules, etc..."
5. - The genetic-societal level, which is typified by the plant. "The outstanding characteristics of these systems are first, a division of labor among **cells** to form a **cell-society** with differentiated and mutually dependent **parts**... and second, a sharp difference between the **genotype** and the **phenotype**, associated with the **phenomenon** of equifinal or "blueprint" **growth**". See **grammar**, **program**.
6. - The animal level, "characterized by increased mobility, **teleological behavior** and self-awareness". As we ascend the scale of animal life, **behaviors** become more diversified, complex and coherently integrated.
7. - The human level: "... the individual human considered as a system... In addition to all, or nearly all, of the characteristics of animal systems, man possesses self **consciousness**, which is something different from mere awareness". **Self-reflexivity** is "... bound up with the **phenomenon** of language and symbolism"
8. - The level of social **organizations**. "The unit of such systems is not perhaps the person - the individual human as such - but the "**role**" - that part of the person which is concerned with the **organization** or **situation** in question"

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Like any other classification, BOULDING's one can be questioned. It is however to be noted that, after nearly 40 years, it has not been basically contradicted by any subsequent experimental or theoretical development.

0550

COMPLEXITY (Conceptual framework for)³⁾

R.L. FLOOD finds that systemic complexity depend on a number of characteristics as follows:

1- The system must include numerous **parts**
 2- These parts must have numerous cross-relations or **interrelations** but must also have **degrees of freedom** (i.e. not be submitted to **constraints** so stringent that it becomes blocked)

3- Quite generally, the system is **non-linear**

Here FLOOD comments: "A feature of **non-linear** systems is that different starting points can cause the system to become **unstable**. They are generally very difficult to understand and commonly "display" **counter-intuitive behavior**, a characteristic of our inability to comprehend **complex systems**" (1987, p.180).

4- The system is generally **asymmetric**, as a result of differential **growth**.

5- The system generally presents non-**holonomic constraints**.

FLOOD comments: "...**parts** of the system are temporarily outside central **control** and can in fact go off. Complexity may therefore arise when there is some sort of localized transient **anarchy** in the system" (p.181).

6- Complexity is also characterized by **hierarchy**, which means that the system's **organization** includes various **levels**, **structurally** different, needed for **regulation** and **control**.

7- Complexity may appear or grow through **emergence**, i.e. the shaping of **organization** at a **meta- or supra level**.

All this is intrinsic complexity. However at human **level of perceptions, values** and **beliefs** still a new **level** of complexity appears" (p.182-3).

0551

COMPLEXITY (Degree of)²⁾

"... the number of distinct **structures** in which various mutual **couplings** can arrange the system's **elements**" (R. FIVAZ, 1991, p.24).

According to FIVAZ: "... the **evolution** of the **complex system** can be seen as an indefinite **sequence of transitions** which activates **structures** and associated **functions** according to external opportunities" (Ibid).

Instead of "**evolution**", it would possibly be better to speak of "**progressive adaptation**".

From another viewpoint, as in H. SIMON **Hora and Tempus parable**, complexity also has a **hierarchical dimension**.

0552

COMPLEXITY (Factors of)¹⁾²⁾

G. WENG et al. write: "In physical systems, complexity is determined by such factors as the number of **components** and the intricacy of the **interfaces** between them, the number and intricacy of conditional **branches**, the degree of **nesting**, and the types of **data structures**. Biological signaling **networks** possess many of these **attributes**, as well as dynamic assembly, **translocation**, degradation and channeling of chemical reactions. All of these **activities** occur simultaneously, and each **component** participates in several different activities" (1999, p.92).

This description, based on the study of molecules and **cells**, seems applicable mutatis mutandis, to all kinds of **social systems** in general.

The distinct **elements**, attributes and types of relationships would have to be identified and described at this higher **level** of complexity

0553

COMPLEXITY from noise principle²⁾

H. ATLAN explains: "These two opposite properties (i.e. **redundancy** and **variety**) appears both as obvious features of what is **organization** and therefore, a good theory must take them both into account in such a way that an optimal **organization** will appear as a kind of compromise between maximum **order** or **redundancy** and maximum **disorder** or **complexity**."

"From then on, it is possible to see how **random perturbations** can produce a change in **organization** by reducing the **redundancy** and increasing the **complexity** of a system, at least, up to a certain point, as long as there is enough **redundancy** to keep the system going.

"This is the so-called complexity from noise principle, at the root of the formal theory of self **organization** that I have worked out several years ago" (1972, p.28-30).

Equivalence between maximum **order** and **redundancy**, or maximum **disorder** and **complexity** is debatable. Maximum **disorder** is generally considered as a completely **random state** or **behaviour** of very numerous **elements**, which is complex only if one considers the massive necessity of **information bits** to describe it. Conversely **redundancy** is **order** only if order is defined as maximum **homogeneity** or uniformity. All this could lead to a serious **semantic muddle**.

0554

COMPLEXITY (Laws of)^{1) - 3)}

J. WARFIELD enunciates 17 "laws of complexity" (1995 a, p.123-52), which he discusses extensively (For details see reference - for many of the **concepts** involved see corresponding entries). The so-called laws are in fact mainly directing **concepts** and principles for the study of

complex issues by **groups**. They should thus be better termed: "Principles for the study of complex issues". Hereafter a somewhat condensed and adapted statement of these "laws"

- "**Triadic compatibility**: The human mind is compatible with the demand to explore **interactions** among a **set** of three **elements**, because it can recall and operate with seven **concepts**, these being three **elements** and their four combinations.

- "**Requisite parsimony**: Every individual's **short-term brain activity** lends itself to dealing simultaneously with approximately seven items... (Law of **triadic compatibility**). Attempts to go beyond this scope of reasoning are met with physiological and psychological **limits** that preclude sound reasoning.

- "**Structural underconceptualization**: No matter what the complex issue, and no matter what the **group** involved in its study, the outcomes of ordinary group **process** (i.e. **process** in which computer support for developing the formal logical **structure** of the issue is lacking) will be structurally **underconceptualized**.

- "**Organizational linguistics drift**: As an organization grows, linguistic separation grows both laterally and vertically in the **organization**. At the higher vertical **levels**, **metaphors** and **categories** become progressively disconnected from the relevant **components** at lower **levels**, leading to **decisions** based on perceived **relations** between **categories** that are not borne out by the **relations** between **category** members.

- "**Validation**: The validity of a science depends upon substantial agreement within the scientific community of **meaning** at its highest grade, i.e. **meaning** attained through **Definition by Relationships**.

- "**Diverse beliefs**: Whatever the **group**, whatever the complex issue being considered by the **group**, at the outset of **group** consideration of the issue, the individual members of the **group** will have quite diverse beliefs about the issue, and the probability is high that this **situation** will remain undiscovered and uncorrected, in the absence of a **group learning** experience using a **methodology** whose power to produce the necessary **learning** has been scientifically validated.

- "**Gradation**: Any conceptual body of **knowledge** can be graded in stages, such that there is one simplest stage, one most comprehensive stage (reflecting the total state of relevant **knowledge**), and intermediate stages whose **content** lies between the two extremes.

(Warfield draws three corollaries from this "law": a corollary of relative **congruence**, one about **diminishing returns** and one about the need to restrict "virtual worlds").

- "**Universal Priors**: The human being, **language**, reasoning through **relationships**, and archival **representations** are universal priors to science" (i.e., there can be no science without each of them).
- "**Inherent conflict**: No matter what the complex issue, and no matter what the group involved in its study, there will be significant inherent **conflict** within the **group** stemming from different **perceptions** of the relative significance of the factors involved in the complex issue".
- "**Limits**: To any **activity** in the universe there exists a corresponding **set** of **limits** upon that **activity** which determines the feasible extent of the **activity**. (Here again, WARFIELD states corollaries):
Corollary of active limits: For any particular **situation**, the **set** of **limits** can be partitioned into two blocks: an active block and an inactive block;
Corollary of movable limits: The **set** of **limits** can also be partitioned into these two blocks: movable and fixed;
Corollary of discretionary action: The movable **subset** of **limits** can be partitioned into these two blocks: movable through discretionary **action** by people, and **autonomously** movable;
Corollary of shifting limits: The membership of the active blocks and the inactive blocks of the **partition** changes with **time**.
- "**Requisite saliency**: There is an underlying logic awaiting discovery in each **design situation** that will reveal the relative saliency of (the various) situational factors.
- "**Success and failure**: There are seven critical factors in the "success bundle" for the **design process**. Inadequacy in any one of these factors may cause failure. The seven factors are: leadership, financial support, **component availability**, **design environment**, designer participation, documentation support, and **design processes** that converge to informed agreement.
- "**Uncorrelated extremes**: No matter what the complex issue, and no matter what the group involved in its study, the *initial* aggregate **group** opinion concerning the logical **pattern** of the factors involved in the issue and the *final* aggregate **group** opinion concerning the logical **pattern** of the factors involved in the issue (i.e., the views at the two extremes of the application of the **Generic Design Science**, before and after) will be uncorrelated; showing that significant **learning** can take place through the application of the **generic design process**.
- "**Requisite variety**: A **design situation** embodies a requirement for **requisite variety** in the **design** specifications. Every **design situation** S implicitly represents an (initially unknown)... dimensionality such as either:

- 1) the **behavior** of the target is outside the **control** of the designer (the target is under-specified), or
- 2) the **behavior** of the target cannot be compatible with the designer's wishes (the target is overspecified).

Only if the **behavior** of the **design** should be what the **situation** can absorb and which the designer can **control**, can the **design process** apply the law of **requisite variety** iteratively, taking in account the **dynamics** of the **situation**.

- "**Forced substitution**: **Underconceptualization** and inherent **conflict** lead to policy vacuums in an **organization** into which authority injects forced **substitution** for absent and inadequate conceptualization, in order to avoid institutional paralysis and for self-protection.
 - "**Precluded resolution**: Forced **substitution** in organizations is dominated by the combination of:
 - structural **underconceptualization**
 - inherent **conflict** and diversity of beliefs
 - dysfunctional **organizational linguistics**, which combine to preclude resolution of complex issues.
 - "**Triadic necessity and sufficiency**: **Relations** are characterized by the number of distinct relational **components**, but no matter how many such **components** a **relation** may have, the (complex) **relation** can always be expressed by **component relations** having no more than three relational **components**; but **triadic relations** exist that cannot be expressed in terms solely of **dyadic** and **monadic relations**".
- This last proposition quite unexpectedly at first sight seems to be related with the **three bodies problem**.

0555

COMPLEXITY (Limits to) ¹⁾

I. PRIGOGINE states this problem in the following way: "The more **elements** that are in **interaction**, the higher the degree of the secular equation determining the characteristic **frequencies** of the system... The greater will therefore also be the chances of this equation's having at least one positive root and hence indicating **instability** (1976, p.123).

H. SIMON, in turn, through his famed parable of the two watchmakers **Hora** and **Tempus** showed how complexity may increase through **hierarchization** of **processes** and **structures**.

The **instability** problem is also subtly related to the **hierarchy** of complexity, since a more global **dynamic stability** may include local **domains** of attraction specifying "islands" of **stability**.

0556

COMPLEXITY (Mathematics of)

→ **Mathematics and Systemics**

0557

COMPLEXITY (Multi-level vs multivariate) ²⁾

T. BAUMGARTNER et al. oppose multi-level to multivariate complexity "... which simply adds more **variables** to the system at the same **level**" (1976, p.38).

According to these authors, a **variable** or **process** at a higher **level** within the system and over some period of **time** "... maintains or is likely to change the **relationships** among the **variables** already considered to be descriptive of the system" (Ibid).

While the **distinction** between higher and lower **hierarchic levels** is important and admittedly, in general **asymmetric** in favor of the higher ones, it seems quite possible that, in some cases, a **variable's** erratic **behavior** at a lower **level** may have general **effects** on the system as a **whole**. This seems specially true in the **social systems** researched by the authors ("For the want of a horseshoe, the battle was lost").

0558

COMPLEXITY of systems ¹⁾

H. SIMON enumerates the following criteria of complexity in systems:

- " 1. Systems with many **components** may be considered complex compared with systems which have few. Thus the cardinality of a set may be considered as a measure of its complexity
2. The systems where there is much **interdependence** between **components** are generally considered more complex than those with less **interdependence** between them
3. Systems which are "undecidable" may be considered complex when compared with **deterministic** ones
4. Complexity of systems may be measured by their **information content**, in the sense of SHANNON-WEAVER. By this **criterion**, systems with many identical **components** are less complex than systems of similar size whose **components** are all different" (1990, p.126).

SIMON also points out that one may also speak of complexity of theories or problems, for example:

- according to the number of **parameters** or **symbols** needed in a theory
- according to the number of elementary **operations** that must be computed in **order** to solve some type of problem
- in relation with computational complexity.

0559

COMPLEXITY (Organized) ^{1) - 2)}

The existence of a **set** of **intermittent** or permanent **interrelations** between a number of interconnected **components**.

The concept was introduced by W. WEAVER. It "involves systems with large number of **components**, rich **interactions** among the **components**, and some degree of **nondeterminism**. They are typical in life, behavioral, social and environmental sciences, as well as in applied fields such as modern technology or medicine" (G. KLIR, 1993, p.35).

Organization is closely related to complexity. In K. DENBIGH's words: "An organized system consists of **parts** and **sub-parts** and these are **interconnected**" (1975, p.85). This author stresses moreover that, "as one cannot speak about something being organized without at one raising the issue, what is it organized for?" (Ibid), organized complexity implies the idea of **function** or **process**.

According to A. RAPOPORT: "Mathematically an "organized complexity" can be viewed as a **set of objects** or **events** whose **description** involves many **variables**, among which there are strong mutual **interdependencies**, so that the resulting system of equations cannot be solved "piece-meal", as in the case of classical celestial mechanics, where **perturbations** can be imposed on **two-body problems**" (1966, p.4).

E. LASZLO writes: "... such **relations** cannot be treated with mathematical rigor with the classical **concepts** (which soon encounter their limitations in the "**three body problem**")" (1992, p.5).

The **holistic** approach has been one of the first new methodological proposal to the study of organized complexity.

It became however rapidly confronted with tricky problems of "inverted **reductionism**" and the resulting useless controversies between "**generalists**" and "**specialists**".

The need to bridge this chasm has led to practically all the **general systems models** developed to date and to the appearance of new mathematical tools as for example **graphs**, **catastrophe theory**, **deterministic chaos**, etc.

0560

COMPLEXITY REDUCTION ²⁾

The main problem for the **survival** of any system is the absolute necessity to adapt and constantly readapt itself to everchanging conditions in its **environment** (and **invironment**).

O. THYSSEN (1995, p. 16) expresses this as follows: "Because of the impossibility of (perfectly) mirroring the environment (or the system itself) in the system, an autopoietic **system** must develop **structures** in order to reduce complexity and create viable simplifications. The means of *reducing* complexity are at the same time the means of *producing* ordered complexity"

→ **Model; Regulator Identity; Reference frame; Variety (Law of requisite); Variety and complexity**

0561

COMPLEXITY THEORY ^{1) - 2)}

Complexity has been first considered under the following aspects:

- **Organismic complexity** as described by L.von BERTALANFFY in his fundational work based on biology.
- **Structural complexity** as for example by J. MILLER in his "**Living Systems**", including the study of **critical subsystems** and the different **levels** of complexity.
- **Hierarchic complexity** as for example by K. BOULDING in his **classification** of systems, or H. SIMON in his "Architecture of complexity"
- **Dynamic complexity** as first considered by H. POINCARÉ in his **three bodies problem**, a work whose all-embracing importance was not understood until the emergence of **chaos** theory.

A more elaborated theory of complexity appeared in recent years, particularly through the work of St. KAUFFMAN, J. HOLLAND, C. LANGTON and others, who see, as any systemist, complexity as the result of **interactions** between **elements**, but are unraveling the ways these interactions work through the study of the **behavior** of **networks**, according to variegated individual **rules**.

Complexity has also been considered from a new viewpoint in **thermodynamics of irreversible systems** by I. PRIGOGINE and the Brussels and Austin's teams which he organized.

→ **Artificial life, Connection machine, Network behavior, Neural network**

0562

COMPLEXITY THRESHOLD ^{1) - 2)}

According to J.von NEUMANN, there is a specific **level** of complexity ("complication", in von NEUMANN's terminology - unfortunately) below which the system spontaneously degenerates into a simpler one and above which it tends to evolve toward a higher degree of complexity.

Such a threshold seems to be related to increasing energy **flows** and thus to PRIGOGINE's **thermodynamics of irreversible systems**, either those dynamically stable, or those affected by **dissipative structuration** through giant **fluctuations**. Implications for the present **transformations** of human societies are considerable, as noted by R.N. ADAMS (1988).

0563

COMPLEXITY (Time Dimension of) ²⁾

According to J.W.S. PRINGLE, the notion of complexity should include not only the **synchronic** complexity of **forms** and **structures**, but also the **diachronic** complexity of **processes**. He expresses this opinion as follows:

"The complexity of the **description** of the **behavior** resides in the number of independent **rhythms** into which it can be analyzed" (1956, p.95).

He thus characterizes the difference between **synchronic** and **diachronic** complexity: "Instead of distinct **parts** of the system which preserve their separateness with the passage of **time**," (i.e. whose **synchronic interrelations** remain invariant at different moments) "we now need to have distinct **rhythms** which remain distinct as they move through the **population**" (p.98).

0564

COMPLEXITY (Unorganized) ²⁾

The statistical **relations** between a great number of seemingly not causally ordered **elements**.

According to I. BLAUBERG, V. SADOVSKY and E. YUDIN: "(Classical science) was chiefly concerned with solving two-**variables** problems, establishing the **causal relations** between two **phenomena**, determining **linear** causal chains for a relatively small number of **objects**" (1977, p.200).

As noted by these authors, this was basically deductive science, and could not cope with "... the problem of discovering the diversity of links and **relations** existing inside the analyzed **object** and its **interactions** with other **objects**" (p.201).

The closest approach to this type of problems was classical statistics, whose laws are basically quantitative and allow merely to tally, classify and extrapolate or interpolate (without much security), i.e. look for some hidden order within "a great number of seemingly not causally ordered **elements**", as for example in **composite systems**.

The expression "Unorganized complexity" was coined by W. WEAVER in 1948, and commented by him as referred to problems "...in which the number of **variables** is very large, and in which each of the many **variables** has a **behavior** which is individually erratic, or perhaps totally unknown. However,... the system as a **whole** possesses certain orderly and analyzable average properties".(1948, p.536).

In G. WEINBERG's words such systems being "...sufficiently **random** in their **behavior**... are sufficiently regular to be studied statistically" (1975, p.16).

WEAVER observed however that in this way, the enormous **domain** of systems with more than two, but less than an astronomical number of **variables** was still left untouched (Ibid). **Chaos theory** is now progressively covering this ground. (See G. BROEKSTRA, 1994, p.1099).

0565

COMPLEXITY (Unwarranted)^{2) - 3)}

A groundless complexity in **modelling codes**.

J.L. LE MOIGNE states: "Many **phenomena** initially perceived as complex (nearly unintelligible or non correctly representable) seem suddenly to become comprehensible when modelers change the **description code**... The Martian orbit that KEPLER desperately tried to describe at the cost of 900 pages of calculation, through a peculiarly complex epicycloid... turned suddenly easy to describe and interpret once the Ptolemaic **code** and the Copernican one of celestial spheres... were replaced by the elliptic **code**" (1990, p.301).

This type of roadblocks to **understanding** is quite frequent. It should however be observed that the inverse situation does exist: Hamiltonian **models** were too simple to explain and modelize **chaos**, as first demonstrated by POINCARÉ.

0566

COMPLEXITY versus SIMPLICITY^{1) - 3)}

The concept of complexity evolved considerably during the 20th century. This historic process is thus described by R. LEFEVER and I. PRIGOGINE: "In the classical perspective, there was a clearcut **distinction** between what was considered to be simple and what had to be considered as complex: There was no hesitation about calling "simple" Newtonian laws of motion, perfect gas, or chemical reactions. Also, one would have called "complex" biological **processes**, and more so human **activities** such as described by economics or urban planning. In this perspective, the aim of classical science was to discover even in **complex systems**, some underlying simple **level**. This **level** would be the carrier of **deterministic** and **time-reversible** laws of nature: Future and past would play the same role. However, this basic **level** remained elusive. Today a far reaching reconceptualization of science is going on. Wherever we look, we find **evolution**, diversification and **instabilities**" (1986, p.2).

Systemics is, in many aspects, fundamentally a science of complexity. As a first step G. WEINBERG distinguishes:

- Organized simplicity (**machines**)
- Unorganized complexity (**aggregates**)
- Organized complexity (systems) (1975, p.18).

Roughly, organized simplicity corresponds to **lineal deterministic machines** (von FOERSTER's **trivial machines**).

Unorganized complexity corresponds to **random interactions** between a great number of **elements** and can be studied through statistical methods. Finally, organized complexity is proper to **nonlinear systems** and is the specific study domain of **systemics**.

0567

COMPLICATED VERSUS COMPLEX¹⁾²⁾

T.F.H. Allen writes: "Complexity needs to be parsed into two parts:

- 1) Complicatedness, and
- 2) Complexity of **organization**

"In hierarchical terms, complicated systems are strongly horizontally differentiated to make a flat **hierarchy**. Such systems exhibit complicated **behavior**

"As systems differentiate horizontally, they tend to differentiate vertically also, developing new **levels of organization** by an elaboration of organization"(1998, p. 5)

Good examples of this process are the **emergence** of a social **phase** in the amoeba *Dicystelium discoideum*, or the present **globalization process** in the **man-planet system**.

Allen adds: "In contrast to horizontal **differentiation**, increased vertical differentiation makes system behavior simpler by collapsing **degrees of freedom**, against the **constraints** coming from the upper **levels**"(Ibid)

0568

COMPLICATION (Principle of)^{1) - 2)}

"Unless some **threshold level of complexity** is reached, there can be no **evolution** of greater **complexity**; below this **threshold**, systems degenerate" (H. PATTEE, 1972, p.35).

It would have been better to call this principle: "Principle of **complexity threshold**"

While this principle is thus enounced by PATTEE, this author expresses his debt to J.von NEUMANN, who wrote (in 1956): "We are all inclined to suspect in a vague way the existence of a **concept** of "complication". This **concept** and its putative properties have never been clearly formulated. We are, however, always tempted to assume that they will work in this way. When an **automaton** performs certain **operations**, they must be expected to be of a lower degree of complication that the **automaton** itself... That is, if A can produce B, than A, in some way must have contained a complete **description** of B. In order to make it effective, there must be, furthermore, various arrangements in A that see to it that this **description** is interpreted and that the constructive **operations** that it calls for are carried out. In this sense, it would therefore seem that a certain degenerating tendency must be expected, some decrease in **complexity** as one **automaton** makes another **automaton**" (1956, p.2092).

An obvious consequence of this concept is the necessity for combinatory **heterogeneity** (genetic, sexual, social, etc...) if **complexity** is to be produced and extended.

An other consequence is that any **auto-poietic** system must contain a permanently usable "blueprint" or **template** of itself.

On the other hand, PATTEE himself comments, however, that: "The scientific **description** of **events** would, in fact, get nowhere in nature's maze of **complexity** unless there were repeated resimplifications which we call **hierarchical levels of description**" (Ibid., p.37).

As shown by J. MILLER in his "**Living Systems**", for example, systemic **isomorphisms** appear throughout the various levels of **description**.

0569

COMPONENT¹⁾

"A unit of a system that in combination with other units functions to combine, separate, or compare the **inputs** to produce **outputs**" (K. BERRIEN, 1968, p.32).

"An integral **part** of a system, selected on the basis of its potential to carry out **functions** required for the achievement of the system's **goal**" (B. BANATHY, 1973, p.85).

The BERRIEN's definition should be compared with J. MILLER's **subsystems**, mainly, but not exclusively, the **converter**, the **producer** and the **associator**. The **outputs** may be intra-systemic, for the use of other **subsystems**. It also seems that components may carry out other tasks in a system. BERRIEN emphasizes that a critical **proximity** is necessary for components to **interact**. He adds that "Once **embedded** in a system, the component to some degree becomes dependent upon the total system for its existence. The greater its specialization, the greater is the **dependence** of the component on the total system" (p.84).

The **distinction** of a component is partly a matter of viewpoint: A component can generally be viewed as a **whole** system when considered at a lower **hierarchic level**. A **cell** is a **complex system** in its own right, but in a living being it acts as a component, because it has entered in a **net of relationships**. In the same sense, a (complex) atom is a component in a molecule, and an individual, itself biologically a complex system, is a component in a **group** or **organization**.

Generally, components are integrated in some more or less permanent **structures**. However, in some cases they may be exchanged between two or more **subsystems** or even circulate more or less freely within the system. Nonetheless, the individual properties of the components become restricted as an effect of their **integration** within a specific system, while they may become associated with other components and produce some collective **behavior** which none of them could produce individually. This is why systemists say that a system is more (and less) than the sum of its components.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

In another aspect, the components of a system are frequently incompatible with other systems. This is the root of immunological rejection and probably, of feuds between nations, cultures, religions and races.

The reproduction **process** of self compatible components by the system is a basic part of the **autopoietic process**.

In relation to higher **levels** of **complexity**, components of lower **levels** frequently belong to a quite limited number of types. There are for example less than 100 basic types of atoms; only 4 nucleotides in DNA chains; and 20 amino-acids for the makeup of proteins. More examples are the basic **binary** units in **computers** or the 20-plus letters in most **languages alphabets**. As observed by H. SIMON, a small number of basic components at any **level** produces simplicity through **redundancy**. (see also: C. BRESCH, 1977).

0570

COMPONENT (Central) ¹⁾

"A component... whose inhibition results in the failure of the entire system" (R. ROSEN, 1960, p.32).

This definition relates obviously to centralized systems and underlines their main cause of fragility, which can be witnessed in many authoritarian **organizations**.

However, even in partly decentralized or **heterogeneous** systems the loss of the central component of critical **subsystems** may provoke the demise of the whole system, as for example the disabling of the **brain**, heart or (both) kidneys in a biological system.

0571

COMPONENTS (Complexity in) ^{1) - 2)}

A characteristic of components made of other components of lesser complexity.

For example, molecules are made of atoms, **cells** are made of molecules, **groups** and societies are made of individuals.

Complexity in components is not merely the result of an additive **process**, as it manifests itself by the appearance of **emergent** properties resulting of the new and specific **interconnections** among the newly associated **elements**.

The assembly of complex components seems to be related to complementary **dis-symmetries**, that may even be **antagonistic**, as long as they are not incompatible. Minimal **sets** of potentially functional assemblies of components have been called '**autogenetic systems precursors**' by V. CSANYI (1989, p.76).

0572

COMPONENTS (Cooperative) ²⁾

Components which maintain **interrelations** with other components in a **network**.

A **network** is normally characterized by allowed **interrelations** while other ones are avoided through **constraints**.

Cooperative **interrelations** of components, when sufficiently observable, can frequently be represented by a **matrix** of stable **transitions**.

0573

COMPONENTS (New) ²⁾

Ch. WALTER thus defines the survival condition of any new components in **populations** (in the LOTKA - VOLTERRA sense, but it seems also valid for components of strongly integrated **living systems**, as **cells**, for instance): "If the new component is to survive, it must interact with its **environment**, and it must maintain itself by a **replication process** that balances the natural **processes** of **dissipation** and **decay**" (1974, p.216).

"Replication" should be understood as **self-reproduction** in the autopoietic sense.

In other words, the new component must be at the same time **adaptable** and **autopoietic**.

0574

COMPONENTS (Unreliable) ²⁾

A great number of unreliable components can become organized in a reliable system through **redundancy** and variability of their **interconnections**.

This field of research was opened by J.von NEUMANN in his 1956 work on "Probabilistic logic and the synthesis of reliable **organisms** from unreliable components".

0575

COMPOSITE SYSTEM ^{1) - 2)}

A system composed of weakly interacting **elements**, all of them of the same **class**.

Such systems should better be named para-systems or quasi-systems because they lack a number of properties characteristic of more **integrated systems**, as for example:

- they have no definite **function**
- they have no **subsystems**
- they are not **autopoietic**, nor **autonomous**
- they are **homogeneous**

Heaps of sand, accumulations of snow in mountains, flowing fluids, stock markets, **populations** and possibly star **clusters** are examples of composite systems. Their basic property is **self-organized criticality**, which makes them subject to runaways and crashes.

0576

COMPRESSIBILITY ^{1) - 3)}

The possibility for an **observer** to reduce the **complexity** of the real world by constructing **algorithms** which produce an ordered and simplified **understanding** of a number of **phenomena**.

J. BARROWS explains: "If it is possible to store the **information** in an abbreviated form shorter than the sequence itself, then the sequence is regarded as non**random** and we call it compressible". If no such abbreviation exists, then the sequence admits no **representation** other than the complete explicit print-out of itself. In this case, we call it "incompressible".

"... this notion of compressibility gives simple ways of characterising many of our intellectual activities. We recognize a possible new definition of "science" as being simply the search for compressions: the laws of Nature are the compressions of our sense **data**. The discovery of a "Theory of Everything" would be the ultimate compression. Moreover, the apparent success of this **process** hinges upon two superficial features of things: the physical world that we observe seems to be surprisingly amenable to compression, and the **brain** is remarkably good at effecting compressions when presented with **events**.

"Clearly, this compressibility and the **brain's** remarkable ability to make sense of complicated things is an important necessary condition for our own existence. We could not survive as "intelligent" **observers**... in a world where no compressions were possible, or with **brains** that produced imaginary or erroneous compressions. A certain **level** of **predictability** and innate predictive power is required for the successful **evolution** and **survival** of living things" (1991, p.43).

Of course, as noted by BARROWS our **brain** can perfectly produce these imaginary or erroneous compressions, as for example "see canals on Mars and all manner of exotic things lurking into inkblots". Thus, let us use **algorithms**, but let us also beware of them!

Cybernetic and systemic **concepts** offer however new tools for compression.

G. KLIR, for instance, proposes his **activity arrays** as compressed **behavior** generating devices, allowing eventual law-discovery **processes** (1975, p.167).

→ **Algorithmic incompressibility**

0577

COMPUTATION (Concepts of) ²⁾

According to Cl. EMMECHE there are two distinct concepts of **computation**. The first one is the representational concept, i.e. "... logical **operations** on **symbols** that can be defined purely **syntactically**, but which nevertheless signify specific numbers and mathematical **operations** (i.e. concepts with a **semantic** content by which we attempt to solve a specific mathematical problem...")

The second one is the physical, or non representational concept, i.e. "... **processes** that not only take place in a **trivial** sense in physical systems (or **models** of these) and are therefore

dependent on their **dynamics**, but which are essentially inherent in these **processes** and demand no further interpretation or adscription of **meaning**" (C. EMMECHE, 1994, p.127-8)

The first concept corresponds to any programmed **digital computer**. The second one would for example be related to the computational activity of **neurons** in the **brain**.

0578

COMPUTER: Analog or Digital;⁵⁾

Still (2004) most computers of common use are digital, i.e. based on **binary hardware** and translation of **data** into **binary codification**. They also are sequential, i.e. doing "one thing at one time and at one place in the arithmetic unit" (K. KRIPPENDORFF, 1986, p.14).

Analog computers on the contrary allow for direct **simulation** through the use of **continuous** physical and analogical **representation of data flows** by, for instance hydraulic or electrical **flows**. However, in KRIPPENDORFF's words, while "there is no restriction on the physical **processes** analog computers may utilize... compared with digital computers, (their) **programming** is time consuming and limited in scope" (p.3).

0579

COMPUTER (Connectionist)⁵⁾

A computer made of many simple computational units, able to do massive **parallel processing**.

The appearance of the **connection machines** and the development of **networks** introduced in recent years new possibilities leading to **distributed parallel processing** and to "machine intelligence" in a more extended sense.

M. BODEN writes: "Connectionist computation is not the manipulation of formal **symbols** by **programmed rules**. It is a **self-organizing process** of **equilibration**, governed by differential equations (which deal with statistical probabilities) and comparable to **energy** exchange in physics" (1990, p.124).

0580

COMPUTER in systems science^{1) - 3)}

G. KLIR states that the computer has "a dual role in **systems science**. In one of the roles it is a methodological tool for dealing with systems problems. In the other role, it serves as a laboratory for experimenting with systems. The purpose of this experimentation is to discover or validate laws of **systems science**". He adds the following important comment: "In contrast to laws of nature, laws of **systems science** characterize properties of various **categories** of systems rather than **categories** of real world objects".

Computers thus can help finding **homomorphisms** and **isomorphisms** between systems in a same **category** or between systems in different ones.

And "The aim of experimentation (with computers) is to discover useful properties characterizing the **category** of systems or, alternatively, to validate some conjectures regarding the **category**" (1993, p.38).

0581

COMPUTER MODELS^{1) - 3)}

G. KLIR states: "As a rule, genuine system problems are computationally extremely difficult. They are often made tractable by overly strong simplifying assumptions that are usually not explicitly stated. The resulting **methods** can then deal with sizeable systems emerging from practical application and produce "impressive" results, but the significance of these results is questionable at best. Such methodological dishonesty is contrary to the spirit of **systems science**. The latter is not interested in producing immediately marketable methodological tools at the cost of convenient simplifying assumptions whose validity is dubious, but rather in pursuing basic methodological research involving genuine systems problems" (1993, p.50).

KLIR proposes better uses of computers in systems science. (see above).

For D. MEADOWS and her collaborators different but not contradictory views, see Model (Computer)

0582

COMPUTERS: Serial and parallel⁵⁾

Already in 1957, J.von NEUMANN distinguished clearly sequential and parallel computers (at a time nobody had yet dreamed of **connection machines**). His **model** of a parallel "computer" was the **brain**. In his own words: "... the natural componentry favors **automata** with more, but slower, organs, while the artificial one favors the reverse arrangement of fewer, but faster, organs. Hence it is to be expected that an efficient organized large natural **automaton** (like the human nervous system) will tend to pick up as many logical (or informational) items as possible **simultaneously**, while an efficiently organized large artificial **automaton** (like a large modern computing machine) will be more likely to do things successively – one thing at a time, or at any rate not so many things at a time. That is, large and efficient natural **automata** are likely to be highly **parallel**, while large and efficient artificial **automata** will tend to be less so, and rather to be **serial**.

"... it should be noted, however, that **parallel** and **serial operation** are not unrestrictedly substitutable for each other... More specifically, not everything **serial** can be immediately **parallelized** – certain **operations** can only be per-

formed after certain others, and not **simultaneously** with them (i.e. they must use the results of the latter). In such a case, the **transition** from a **serial** scheme to a **parallel** one may be impossible, or it may be possible but only concurrently with a **change** in the logical approach and **organization** of the procedure. Conversely, the desire to **serialize** a **parallel** procedure may impose new requirements, since the results of the **operations** that are performed first must be stored while the **operations** that come after these are performed. Hence the logical approach and **structure** in natural **automata** may be expected to differ widely from those in artificial **automata**. Also, it is likely that the **memory** requirements of the latter will turn out to be systematically more severe than those of the former" (1958, p.50-52).

In effect, the **parallel automaton** – natural or artificial – does progressively construct **algorithms** through the application of a **set of rules** in its **network**, while the **serial**, i.e. sequential one is based on a previously introduced **deterministic algorithm**, which may of course be quite complex.

The treatment of complex **networks models** by sequential computers is inevitably distorted, as for example in the case of FORRESTER's **systems dynamics**.

R.W. FULLER and P. PUTNAM clarified still more this matter: "The **parallel** calculator functions to pick up **correlations**, to sift for and to isolate significant new **correlations**, while the series calculator is designed to help establish the consequences of **correlations** already well defined (Like NEWTON's laws)" (1967, p.99).

0583

CONATION²⁾³⁾

The aspect of mental **process**, or **behavior** directed toward **action** or **change**(Amer.Her. Dict., p. 276)

Conation derives from "conatus", latin word for attempt, effort, endeavor.

Conation behavior is related to impulses and desires, but translates these to **volition** and intentional action.

It seems to imply a **coordination** between different **levels** of the central **nervous system**.

→ **Behavior (Anticipatory)**

0584

CONCATENATION¹⁾²⁾

→ **Organization: a descriptive language**

0585

CONCENTRATION¹⁾⁴⁾⁵⁾

The gathering of a significant number of **elements** within a limited **space**.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

Concentration is a widespread **process** among animals and people. It obeys to a **variety** of causes, possibly the most basic is related to **thermodynamics** and **entropy production**. (Prigogine's theorem of **minimum entropy production** and his **model of structuration** through **dissipation of energy**)

Concentration may result from specific environmental pressure, as in the cases of the amoeba *Dictyostelium discoideum* or some species of locusts mutating to their gregarious **phase**.

In fishes and in birds, concentration leads to protective **herd effects** and in social insects it has similar but much more complex effects.

It seems that, in all cases of concentration, some specific factor of reciprocal **perception** is at work. In many animal species **pheromones** are such factors. Once reciprocal **perception** is activated, it tends to become self-maintaining, or even self-reinforcing. A very suggestive case is **stigmergy**, in termites societies where close contacts lead to positive **behavioral feedback** and introduce the possibility of constructive social **coordination**.

In fact, the gathering of elements, formerly unconnected and behaviorally independent, seems to be a condition for the **emergence** of systems of higher **levels of complexity**, in a kind of **self-organizing cybernetic process**. V. Csanyi described this transformation as **auto-genesis**.

The human species is of course by far the most self-concentrating species. Its "pheromone" is **language** and its **efficiency** is in the transmission of **information**. Human concentration has been accelerating all along history and the present growing megalopolis are the most outstanding example of this trend.

→ **Hexagonal space filling; Implosion; Node (critical); Stimulus; Threshold; Tropism; Zero-system**

0586

CONCEPT ³⁾ - 4)

The general **meaning** given to a word or a **set** of words

According to E. BUCHBERGER: "A concept is an ordering **representation** of what are considered to be the necessary and sufficient characteristics of a **set of objects**" (1987, p.77). An example is "dog" as a general term applied to numerous different animals, all of whom however share some common characteristics.

These definitions conceal tricky **semantic** problems, on different **levels**: psychological, social and cultural.

J.Z. YOUNG thus expresses the psychological one, defining the concept as: "The learned **program** for the use of a word or a **set of words**" (1978, p.291). The word "learned" conveys perfectly PIRANDELLO's quip according to which we "merely chew again the dialogue of

the dead ones" (in "Henry IV"). As to the social aspect, no concept has ever a **communication value** if not commonly accepted as such and **validated** by recurrent **consensus** through **conversation** "a la PASK".

The cultural aspect has been considered by M. MARUYAMA in his studies on "**mindscape**s" (1966, etc.). **Transcultural consensus** on concepts is even more difficult and insecure than the social **consensus** within a same culture. This could be called the "**semantic declination**", somehow analogous to the magnetic declination.

In any case, as stated by K. KRIPPENDORFF: "Concepts are neither true nor false, but more or less applicable (a) to recognize an **object** as an instance of the concept (**recognition**), (b) to produce or to understand sentences in which the concept is expressed and (c) to develop **constructs** or **cognitive systems** using the concept in question" (1986, p.14).

To round off, WITTGENSTEIN's pun: "Concept" is a vague concept" (as quoted by EDELMAN, 1992, chapter 10th' epigraph) is quite more than a pun.

0587

CONCEPT AND PERCEPT ³⁾

L.von BERTALANFFY called for the **interaction** and **integration** of percepts and concepts: "Analysis has to proceed at two **levels**: that of *phenomenology*, that is of direct experience, encompassing **perception** of outside things, feelings, thinking, willing, etc.; and of *conceptual constructs*, the reconstruction of direct experience in systems of **symbols**, culminating in science; it being well understood that there is no absolute gap between percept and concept, but that the two **levels** intergrade and interact" (1967, p.94).

Such **interaction** and **integration** is a permanent feature of human mind. However, it has not yet been generally recognized, due to the dominant tendency to reification.

Neither percept nor concept are "pure". Any concept is an ordered **abstraction** of former percepts, and any percept is "tainted" by formerly acquired concepts. It all must necessarily start in the newborn **brain**, through some basic **rules of neuronal nets operation**.

On this topic, J.W. SUTHERLAND even writes: "... simply because a concept developed ab intra (with no *apparent* empirical groundings) there is no guarantee that it will not be real - i.e., there is always a possibility that a congerie of man's mind might parallel a congerie of nature. Hence, the concept has the same a priori right to be considered by science as the percept" (1973, p.84).

0588

CONCEPT (Components of a) ³⁾

According to A. and H. DAMASIO: "Concepts are stored in the **brain** in the form of "dormant" records. When these records are reactivated, they can re-create the varied sensations and **actions** associated with a particular entity or **category** of entities. A coffee cup, for example, can evoke visual and tactile **representations** of its shape, color, texture and warmth, along with the smell and taste of the coffee or the **path** that the hand and the arm take to bring the cup from the table to the lips. All these **representations** are re-created in separate **brain** regions, but their reconstruction occurs fairly simultaneously" (1992, p.70).

This **understanding** of concepts retrieving (or constructions) is based on the **model** of interconnected **neural network** in the **brain**, including **mediation layers**, specially studied by these authors.

0589

CONCEPT (Context-dependent) ³⁾

M. KUBAT comments: "In the real world, concepts are usually not crisp but, rather, tend to change (more or less) their **meaning** with **context**" (1992, p.392).

L. THAYER explained this by the existence of what he called "**epistemic communities**", each with a specific **understanding** of every concept, obtained by a (progressively shifting) **consensus** (1972, p.112). In every **community**, **language** use is largely an **autopoietic process**.

According to W. FRITZ, who bases himself on his experiments with **artificial intelligent systems** (on a digital computer), experiences leading to positive or negative results are registered by the system and their comparison and **accumulation** derive in "actuation **rules**" (i.e. prescriptions about suitable **action** in specific **situations**), which are stored for possible subsequent use. These **rules** can undergo **reinforcements**, be transformed or forgotten. They are created on different **levels**: practical **motor habits** (for instance, riding a bicycle); practical **habits** with a neuro-mental **component** (driving a car); linguistic **habits**, etc... For FRITZ, the most abstract and general **rules** are those called **concepts**, because they are a multi-use synthesis of many experiments (pers. comm.).

These ideas are consonant with A. KORZYBSKI's **structural differential**, a general **model** of the way we extract **abstractions** at various **levels** from observed **events**.

0590

CONCEPT CROSSING ¹⁾ - ³⁾

"The combination of concepts from different **fields** of specialization" (M. MARUYAMA, 1985, p.387).

Concept crossing produces cross fertilization of ideas and techniques, and enhances **creativity**. By **analogy** with A. KOESTLER's concept of **bisociation**, it could be called "multisociation".

According to MARUYAMA, this technique should be associated with **design looping** and **experience looping**. In this way it becomes possible to evade from **lineal causal** stereotypes (1994, p.37).

0591

CONCEPTUAL BLOCKING ⁴⁾

K. BAILEY writes: "Conceptual blocking occurs when use of some vital **concept** is precluded within a **paradigm** by the use of some other concept which contradicts or prohibits its use. For example, PARSONS over reliance on the concept of **equilibrium** in his **social systems theory** precluded or blocked the effective analysis of social change in systems not characterized by equilibrium. That is, if the concept was said to be equilibrium, this was defined in such a way that **change** was minimized or short lived. Further, since only systems in equilibrium were emphasized, the analysis of change in other systems was neglected" (1996, p. 8)

As an example, PRIGOGINE's **model of dissipative structuration in systems far from equilibrium** seems to be a much more adequate conceptual **frame of references**.

For an **explanation** of the deep and accelerated evolution of our **man-planetary system** and associated **technosphere**.

→ **Blindsports; Entropy production (minimum); Methodological pluralism; Model building; Sociognosis; Sociosphere; Sociotechnical system**

0592

CONCEPTUAL MODEL ²⁾

A systemic account of a **human activity system**, built on the basis of that system's **root definition**, usually in the form of a structured **set** of verbs in the imperative mood" (R. RODRIGUEZ ULLOA, Glossary, 1999)

"Such models should contain the minimum necessary **activities** for the system to be the one named in the **root definition**. Only **activities** which could be directly carried out should be included - thus admonishments such as "succeed" must be avoided

"Conceptual models may be validated or justified only in terms of logic, not be **mapping** on to the real world, since they do not purport to describe the real world. They may however be compared with the **formal system model** in order to check that they are not fundamentally deficient" (Ibid).

→ **Truth**

0593

CONCEPTUAL SITUATION ³⁾

The mind **state** of the user of a **language**, "i.e. a **structure** made up of certain items and certain **relations**" (after. E.von GLASERSFELD, 1988, p.6).

The conceptual situation exists "regardless of whether the **structure** could be said to have originated in **perception**, in imagination, or even as an illusion".

In effect, the linguistic expression will be identical whether it describes a phantasy, a hallucination, or what is called observable reality" (Ibid).

Any possible differentiation could emerge only if the speaker has a clear **semantic understanding** of his/her own conceptual condition, quite a difficult achievement.

→ **"Semantics (General)"**.

0594

CONCEPTUAL SPACE ^{3) - 4)}

The **domain** open to search, research and creation as delimited by existing mental **constraints**.

This notion, developed by M. BODEN in her inquiry in natural and **artificial intelligence**, is closely related to the **paradigm** concept. To any conceptual space corresponds a system of **generative rules** (or a generative system) that defines the possible research **space**. In M. BODEN's terms, it is a kind of "**map** ... used to generate an indefinite number of very useful "coulds" and "cannots" (1990, p.47).

(BODEN's **generative rules** seem to be very close to FRITZ' **actuation rules**).

Or: "... a conceptual space (or a family of neighbouring conceptual spaces), whose potential is both created and limited by the **constraints** concerned" (p.158).

In a conceptual space, **congruences** are established in accordance with the ordering **constraints**.

Should the **generative** system be modified, the conceptual space would be to. This happens for example when one emigrates into another culture, or start to work in a different discipline. M. BODEN states: "The deeper the **change** in the **generative** system, the more different - and less immediately intelligible - is the corresponding conceptual space" (p.81).

The conceptual space is progressively acquired through **learning** and ends up with a kind of **autopoietic** mental **closure**, which however implies the previous internalization of simpler **competences** and **maps**, i.e. ordering **constraints**. In M. BODEN's words: "These **representations** arise on several successive **levels**, each time enabling the person to exploit the prior **knowledge** in ways that were not

possible before. The person progresses from one skill that is fluent but *automatic* (being varied only with much effort and little success) to one that can be altered in many ways" (p.64).

The subject is closely related to the "**creativity**" one.

0595

CONDENSATION ²⁾

The reduction of **redundancy** in a **message**.

As some **messages** are very **redundant**, condensation may be quite useful for an optimal use of the **channel** as well as for the **decoder's** job.

However, a total elimination of any **redundancy** is dangerous, because the slightest **noise** in the **channel** would impair the **understanding** of the **message** for the **receiver**.

According to R. ACKOFF and F. EMERY, condensation may either "reduce the receiving **time** required" (using a *digest* of the **message**), or "provide a brief **description** of its **content**" (using an *abstract*).

A third way seems sometimes available, somehow equivalent to the second one, at least for suitably organized or trained systems: use one brief conventional **sign** or **symbol** representative of the whole **message**. Roads signposts are **symbols** of this kind.

0596

CONDITIONAL PROBABILITIES MATRIX ²⁾

"A matrix determining the relative probabilities of various **patterns** (and **patterns** of **patterns**) of **behavior** in all possible circumstances" (1969, p.95).

Mac KAY expresses this also in the following alternative way: "A **hierarchic structure** of organizing "sub-routines" to determine these conditional probabilities interlocked in such a way as to represent implicitly the **structure** of the **environment** (the world of **activity**) with which the **organism** must **interact**. For many **purposes**, we may reduce it to the filling-out of a world-map, ready to be consulted according to current needs and **goals**" (Ibid).

These very interesting definitions evoke:

1 - K. STEINBUCH's "**Learn-matrixes**" through which a system is establishing **connections** between specific **signs** and specific **meanings**.

2 - H. MATURANA and F. VARELA "**organizational closure**" according to which everything which happens to a system happens within the system and then only within the **limits** of the predefined **capacity** of **autopoiesis** (**self-reproduction**) of the system. (Remains to explain wherefrom this **capacity** comes into being and why and how it becomes closed).

3 - W.R. ASHBY's "Law of **requisite variety**" and **concept** of **constraint**.

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

4 – the incapacity for any system to construct a complete and totally trustworthy **map** of the world wherein it exists; as shown by A. KORZYBSKI (1933, 1950).

0597

CONDITIONED REFLEX→ **Reflex (Conditioned)**

0598

CONDITIONS (Initial)^{1) – 2)}

The **state** of a system at the beginning of its **activity**, or when an **observer** starts to observe it.

Authors like M. MARUYAMA, H. von FOERSTER and others insist on the importance of initial conditions as determinants of the nature of a system a-building.

The first one is the **substrate** or **environmental** conditions. No system is constructed in a void. Even in abstract **models** like in Go, in CONWAY's **Games of life** or in MARUYAMA's **deviation-amplification processes**, the **substrate** is a grid with specified properties, as for example, being formed of adjacent squares and having (or no) spatial **limits** in two or more **dimensions**.

For **living systems**, the initial conditions are clearly defined in each case by biological **constraints**, which are absolutely unavoidable.

Another initial condition is the **homogeneous** or **heterogeneous** nature of the original **elements**, which is paramount for their future ways of **interaction**. (**Clustering**, **symbiosis**, **organizational closure**, etc...).

A third one is their reciprocal **localization**, whose importance is visible in Go, in chess, or in CONWAY's games, and now also better known in embryogenesis, where they are paramount for an ordered **development** of the **living system**.

Finally, the question of the **interaction rules** is somewhat puzzling. Whereas introduced or potentially inscribed somewhere in the initial **situation**, they are undoubtedly themselves a most important initial condition: Different **development rules** will necessarily produce different systems, even if all other conditions are identical.

For the importance of **sensitivity to initial conditions** for the onset of **deterministic chaos**, see "Sensitivity to ..."

→ **Zero System**

0599

CONFIGURATION³⁾

"Any **phenomenon** that can be distinguished" (F. HEYLIGHEN, 1992, p.4).

According to HEYLIGHEN, the concept includes "anything that is called feature, property, **state**, **pattern**, **structure** or **system**" (Ibid).

"Configuration" implies at least the notion of some kind of *non random* arrangement of **elements**.

HEYLIGHEN adds the following: "The selective retention of a stable configuration depends essentially on two factors: the configuration must be intrinsically **stable** (internal **selection**), and able to resist **changes** in its **environment** (external **selection**)" (pers.comm.).

G. BROEKSTRA considers configuration: "... as a **holistic structural** manifestation of the interplay of the underlying **processes**" (1993, p.76).

0600

CONFIGURATION (Initial)^{2) – 5)}

The original ordering of the first **elements** of a **cellular automaton**.

P. GREUSSAY comments about the **dynamics** of the **automaton**: "The **set** of the **states** of the **cells** is the 'genetic material' of the initial configuration... **Self reproduction** is actively directed by the initial configuration itself, though a **transitions function**" (1988, p.1322).

This **function** depends on a **transition rule** or **set of rules**, as for example in MARUYAMA's **deviation amplification mutual causal processes** or in J. CONWAY's **games of life**.

0601

CONFIGURATOR²⁾

"A special **model** of the **object**, exercising the methodological function of **synthesis**" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.123).

According to these authors: "This **model** has to be evolved in such a way as to coordinate different notions of the **object** and explain each of them as a particular "cross-section" or angle from which the **object** is viewed. Of special significance is the fact that the researcher, using the configurator **model** for presenting the **object** as a system, has to start out from the idea of the systemic **structure** of the given **object**."

"The initial notion is of a hypothetical character and is more precise in the course of further theoretical treatment of the **object**" (Ibid).

0602

CONFIRMATION³⁾

1. A result of **perception** of **redundancy** in a **message** registered by a **receiver**.

Confirmation may act as an **operator** and lead to **reinforcement**.

2. "The support given to a hypothesis or **model** (a) by evidence available in the form of **data** or **observations** or (b) by logical deduction from premises, ultimately from the axioms of a formal system" (K. KRIPPENDORFF, 1986, p.15).

This could be considered a near synonym of "**validation**"

0603

CONFLICT: Some proposed systemic views⁴⁾

Conflict is for human systems, **competition** led to extremes. K. KRIPPENDORFF defines conflict as: "A state of affairs in which two or more parties claim possession of something not all can have simultaneously" (1986, p.16).

Conflict seems to be a normal result of the presence of two or various systems vying for the same **resources**, particularly when these are scarce. While it may lead to the destruction of one of the antagonists, it generally ends through a **process** of reciprocal **adaptation** through the establishment of some **regulating mechanism**, which of course has to be paid for and must thus be **cost-effective** if it is to persist. The repetition of such **processes** at different **levels** leads to the apparition of a stratified **hierarchy** of **regulators**, a **phenomenon** quite apparent in any **complex system**.

Conflict may appear anew if some modification in the **environment** turns out to be favorable to some of the competing systems and unfavorable for others.

Conflict also presents an **evolutive** aspect.

When some modification intervenes in the nature or **behavior** of a system, as interacting **part** of a **suprasystem**, new reciprocal **adjustments** become generally unavoidable as a result of the propagating impact. This, frequently results in new conflicts, which in turn lead to new **processes** of reciprocal **adaptation**.

Conflict can also appear between **percepts**, **concepts**, **models**, etc... constructed by different **observers**.

R. ROSEN states: "In each specific case, it appeared that the roots of the conflict lay not so much in any particular objective **situation**, but rather in the fact that different **models** of that **situation** had been adopted by the different parties in the conflict. Consequently, different **predictions** about that **situation** were made by these parties, and incompatible courses of **action** adopted thereby. Therefore, a general theory of policy making (or, as I would argue, a general theory of **modelling**) would have as a corollary a theory of conflict and I hoped of conflict resolution" (1991c, p.543).

This has also been expressed by J. WARFIELD as the

Law of inherent conflict

"No matter what the complex issue, and no matter what the **group** involved in its study, there will be significant inherent conflict within the **group** stemming from different **perceptions** of the relative significance of the factors involved in the complex issue" (1991, p.200).

WARFIELD even states that in most cases, all participants will be wrong in some sense. The

roots of this situation are in **cognitive** and emotional differences. It could also be related to differences in **mindscapes**, in MARUYAMA's sense.

The real systemic problem with conflict is thus: How can we convince people (even honest ones, not to speak of the others!) to discuss in a critical way their own **viewpoint**, to try to reach **consensus** and to negotiate more or less satisfactory solutions. It is really a problem in applied social **methodology**.

More recently the conflict solving problem has been tackled by the Austrian sociologist G. SCHWARZ (1999)

This author proposes a **process** of conflict solving that takes in account the generally observed conflict **situations**.

- 1- escape: "run away"
- 2- destruction: "kill your opponent"
- 3- submission: "subordinate your opponent"
- 4- delegation: an independent authority (judge) decides the solution
- 5- compromise: an arrangement between the two positions
- 6- consense: seeking for a dialectical synthesis

According to Schwarz these six levels form a kind of order or **learning process**. Of course the learning can be cut short at any of the three first stages. If not, the process can take place

- a) as a progress in an inter-individual conflict
- b) as a progress in the **consciousness** of conflicts in a person or **organization**
- c) as a progress of the social abilities of mankind as a whole to manage conflicts

(As quoted from G. OSSIMITZ, 2000, p. 2)

0604

CONFLUENT²⁾

The collecting point, area or volume of a number of **lines of behavior**.

This is the name W.R. ASHBY gave to what is now generally known as an **attractor** (1960, p.185). Each confluent corresponds either to a **state of equilibrium** or to a closed **cycle** of specific **states** (in topological terminology a **vicinity**, or a **basin**).

According to St. BEER, a confluent is structured by a **set** of lines of **entropic drift** (1968, p.476).

In **homeostatic** systems, any **process** tends to return to its proper confluent until ejected from its **basin** by some very strong **disturbance**.

0605

CONFORMATION¹⁾

→ **Organization: a descriptive language**

0606

CONGERIES²⁾

A reunion. of uncoordinated **elements**.

This (plural) term generally used as a singular, is an infrequent synonym for "**aggregate**".

0607

CONGLOMERATE¹⁾²⁾

A non-ordered **collection** of **elements**.

The elements can be of the same kind or different ones, and do not exhibit a common **autonomous behavior** or **synergy**.

In some cases the conglomerate may however show a tendency toward **organization**, possibly under changing environmental conditions.

→ **Cluster; Congeries; School; Shoal; Stigmergy; Swarm; Zero-system**

0608

CONGRUENCE (Structural)^{3) - 4)}

1 The basic and limitative **organization** of our capacity as an **observer** and actor.

2- The basic and limitative **organization** of the global capacity as **observers** of some **group** of individuals (probably in social animals, as well as in humans).

The first **level** of structural congruence refers to the individual and has the following roots:

a) it results from the progressive **learning**, which is slightly or vastly different from one individual to another, and organizes a specific **conceptual space** on the basis of defined **constraints**, for each of us (for example, the **rules** of harmony for an 18th Century composer).

Apart from basic physiological limitations to **perception**, **learning** differentiates and refines some perceptive abilities, while it stifles others. The mind ends up with a kind of general congruence of **autopoietic** character and a great number of more specific congruences (for example between the specific techniques in a profession, or driving a car).

b) individual **learning** reflects of course collective **mindscapes**, which frame it and orient it toward specific capabilities and **inhibitions**, defined by the culture. The second **level** of structural congruence is a result and also the basis of **communication**. It is constantly reconstructed by a **process** of shifting **consensus** and becomes reflected for example in **semantic polysemy** and the slow **evolution** of natural **languages**.

0609

CONJUNCTION^{1) - 2)}

The joining of **elements** to constitute a system.

This term has been introduced by A. BOGDANOV as early as 1922. It is still generally ignored and unused.

This is curious, since the reunion of **elements** that start to interact is obviously the foundational act of any system.

0610

CONNECTANCE^{2) - 4)}

"A measure of system **connectedness** based upon the mean number of nonzero **interaction** terms per **compartment** of the system under consideration" (T.F.S. ALLEN & T.B. STARR, 1982, p.264).

This definition should be completed by the following comment of W.D. GROSSMANN and K.E.F. WATT in reference to the evermore intense **interactions** of all types between human individuals and **groups**: "Excessively intense or frequent causal **connections** between systems or systems **subcomponents** can foster rapid **propagation** of shock **waves**, or internal **perturbations** within systems. At present nobody can tell to what degree **connectivity** is tolerable on a global scale...

"What are the preconditions for avoiding the present high degree of **interactions** becoming threatening?" (1992, p.9).

This clearly systemic problem, that also can be observed in animal **populations**, has been formerly studied by J.B. CALHOUN from the slightly different angle of the relation between **population density** and social pathology by **overcrowding** (1962 and 1971).

→ "**Connectivity**", a near synonym.

0611

CONNECTANCE²⁾

The percentages of **links**, between the **elements** in a **network**.

The concept also appeared recently in **ecology** (A. FLOOD, 2001, p. 30-33). N. MARTINEZ introduced the "constant-connectance hypothesis according to which "a particular balance of food-**web complexity** exists in nature...- between everything eating everything, and everything not eating everything, and everything eating nothing (see R. WILLIAMS and N. MARTINEZ, 2000) "

Connectance is related to the global **stability** or **instability** of the network and is thus characteristic of its **emerging complexity**.

FLOOD comments: "**Distributions** of species, the World Wide Web and metabolic networks all seem to show robust **self-organization phenomena**. It is the global features of such **webs** that matter, not the individual characteristics of the units that make them up"(p. 33)

In **ecological networks** "a species (may go) extinct because of the removal of a closely connected neighbour"(ibid.)

This can be obviously happen in economic and in social networks.

→ **Graphs; Power laws; Small world**

0612

CONNECTED COMPONENT²⁾

"A component of a system which is involved in at least one of the main lines of **communication** of the system" (T.F.H. ALLEN & T.B. STARR, 1982, p.264).

0613

CONNECTEDNESS²⁾

The degree of interconnexion of an **element** with other ones in a **network**.

"A general term for the cohesiveness of a system" (T.F.H. ALLEN & T.B. STARR, 1982, p.264).

ALLEN and STARR comment: "Systems with strong **interaction** terms are relatively highly connected, as are systems with a large number of the **parts** interconnected (as measured by connectivity and connectance)" (Ibid).

0614

CONNECTEDNESS (Degree of)^{1) - 2)}

ASHBY discussed the connectedness among **elements** within **complex systems**. He insisted that such **systems** are neither fully connected, nor totally unconnected.

He wrote: "The separation into many **parts** and the union into a single **whole** are simply the two extremes on the **scale** of "degree of connectedness". He added: "**Adaptation** ... demands not only the **integration** of related **activities** but the **independence** of unrelated **activities**" (1960, p.157).

Moreover, the degree of connectedness may vary in different **subsystems** and also with **time**.

Strong or weak connectedness corresponds to the **richly or poorly joined systems** or **environments**, in the somewhat peculiar vocabulary of ASHBY.

Finally, the degree of connectedness defines the system's **constraints**.

0615

CONNECTEDNESS (Excess of)^{1) - 2) - 4)}

A system is basically a **set** of interconnected **elements**.

However, the degree of connectedness varies widely according to the type of systems. While a **composite system** is very weakly connected, differentiation in more **complex systems** is related to selective **connections** between **parts** or **elements**, which define global and local **functions**. It can be closely related to **heterogeneity** obtained by **constraints**.

A totally connected system should be absolutely determined and thus completely unable to adapt itself to new **situations**.

According to ASHBY "...for the **accumulation** of **adaptations** to be possible, the system must not be fully **joined** (i.e. connected)... certain **parts** should not communicate to, or have an

effect on certain other **parts**". Hence, ASHBY points out that "The **Homeostat**...is too well integrated, cannot accumulate **adaptations**" and "...it must not be overlooked that **adaptation** may demand **independence** (of the **parts**) as well as **interaction**" and yet...

"...by developing partial, fluctuating and temporary **independencies** within the **whole**,... the **whole** becomes an assembly of **subsystems**, within which **communication** is rich and between which it is more restricted" (1960, p.255-257).

Good examples are the different **organs** within a **living system** or the distinct sections within an enterprise.

0616

CONNECTION^{1) - 2)}

A more or less permanent or repetitive **interrelation** between two or more **elements**.

Connections are of many different kinds. See: "**Connections (a classification of)**" and "**connection modes**"

Any connection implies the propagation of some **flow** from one **element** to the other(s). The **flows** may be of **matter**, **energy** or **information**, inasmuch as it is possible to distinguish them.

The **interrelation** is either one-way, or reciprocal.

Connections in a system can generally be represented through **graphs** or **matrixes**. This is more easy for **ergodic systems**, after a statistical study of the succession of **states**.

W. PAULI observed long ago (1954) that the use in physics of "statistical laws of nature with primary **probabilities**" shows a tendency to amplify the older more narrow idea of "**causality (determinism)**" to a more general form of "connections" in nature (1954, p. 301)

Indeed it has been seen more recently that connections may be inscribed in **self-organized criticality**, in **fractals** and in **chaotic interrelations**

0617

CONNECTION MACHINE⁵⁾

A massively **parallel** computer.

The connection machine has been conceived by D. HILLIS and deeply differs from the common **parallel computers**, which are practically working as a bundle of multi-**sequential** machines.

HILLIS' machine is a **network** of numerous individual **binary processors**, whose **interconnections** are organized within a complex multi-dimensional **net**. (see "**hypercube architecture**").

J. BRIGGS and F.D. PEAT write: "According to connectionists... computer **programs** should not be **sets** of logical instructions aiming at producing predictable results; they should, on

the contrary, be simply instructions aimed at varying the weights of connections among **processors**, leading in this way the machine to construct **nonlinear networks**" (1991, p.174).

0618

CONNECTION MODES²⁾

Connections among **elements** can be arranged in a number of different ways:

On line: The **elements** are connected in such a way that each one is linked only with its antecedent and its successor on a line. This is a very limited and restrictive way to connect **elements**.

Ring: The **elements** are still connected on line, but the last one is again connected with the first one as its successor. Rings may allow for **feed-back**, for **catalysis**, for **organizational closure** and for **hypercycles**.

Tree: The **elements** are arranged in such a way that each one becomes a **node** with one connection upstream and one, two, or generally more downstream. **Hierarchies** can be represented by trees.

Crossbar: In this arrangement, every **element** is connected to every other one. However, the number of connections grows as the square of the number of **elements**. Without **constraints**, **structures** of this kind become clogged and generally undefined for any specific use.

Three or more dimensional structures: as for example cubic or **hypercubic nets**. This mode of connection allows for **constraints** by trade-offs between the number of direct connections permitted to each **element** and the minimum and maximum length of the **communication** line between two **elements** not directly connected. Every **structure** of this type is a **net**.

Nets of nets: Such three or more dimensional **nets** can be interconnected. This **mode** allows for many local **nets** to become integrated within a global one, while maintaining some **autonomy** and **specialization**. **Brains**, **connection machines** and societies are probably amenable to be thus modelled.

0619

CONNECTION (System forming)¹⁾

A type of connection specific to organized **wholes**.

I. BLAUBERG, V. SADOVSKY and E. YUDIN speak of "organic" **wholes**, which seems unduly restrictive. (1977, p.145).

Connections are essential in systems: no unconnected number of **elements** can ever be considered a system. Even **composite systems** are weakly connected, through the general conditions to which they are submitted.

On the other hand, isolated or temporary connections are not significant, from the systems point of view. Systems are multi-connected and, moreover, generally made of interconnected **subsystems**, themselves made of connected **components**.

However, connections are selectively restricted and organized within the system, whose internal **constraints** give it a specific identity and functionality.

In systems, connections form **networks**, generally at different **levels**. Each system has its characteristic **networks**. Individual connections cannot be well understood if considered independently from the **networks**. This is why G. WEINBERG proposes a "Strong Connection Law" (1975, p.158), in order to do away with some principles of **reductionist** scientific **methodology** that cannot be applied to the study of systems, as for example:

- "Clear logical thinking requires that we vary only one factor at a time" (In a system, varying one factor triggers a chain **reaction** in the connective **network**)
- "All other things being equal..." (Systems are dynamic: nothing ever remains equal).

0620

CONNECTIONISM^{1) - 5)}

Parallel distributed computing within interconnected **nets**.

A system also can be understood as a **net** of simple **components** with **propagation** of **flows**.

E. ANDREEWSKY explains: "According to Connectionism, the **brain** and its neurons explain **behavior**, and the terms used in this field, such as neurons, synapses, **activation**, **propagation**, suggest a biological explanation for cognitive **phenomena**. The former **A.I.** abstract symbolic **representations** become a **set** of very simple **elements (formal neurons)** functioning in **parallel**. Like the **perceptron**, connectionist systems work through **learning**... Connectionist systems do not have central units, and each of their **elements** functions in its local **environment** in order to determine a **global cooperation**, that is the system's **organization**. The **network** shapes itself progressively with the **stimuli** it receives; in other words, its **learning activity**, which is continuous during its implementation, results in **changes of the network itself** (whereas classically, **learning** is only **change in knowledge representation**)" (1993, p.192-193).

Of course "**change in knowledge representation**" implies the previous existence of **knowledge**. Thus such a view of **learning** does not explain the genesis, or better, the **autogenesis of knowledge**.

The physio-psychological version of connectionism is an extension of D. RUMELHART, J. MCCLELLAND and G. HINTON's **Parallel Distributed Processing**, which is a **model** for **information processing**.

As to the **mechanism** of connectionist construction, E. ANDREEWSKY resumes J. MCCLELLAND and D. RUMELHART explanations: "The **communication** between the different units of this system no longer takes place by means of **messages** as in classical **Artificial Intelligence**, but through **activation values**: numbers and not **symbols**. The interpretation of the **operation** is no longer obtained in terms of **messages** transmitted between **modules** of the system; it represents the activated **states of the whole system**" (p.193).

Moreover, and in accordance with D. HEBB's **reinforcement** through repeated **stimulation**, connectionism implies **reinforcement** of pathways by frequent use.

Connectionism is also obviously and closely related to the more general problem of **auto-genesis in living** and in **social systems**.

Connectionist network: "A **parallel-processing** system made of many simple computational units, linked (as **brain-cells** are) by excitatory or inhibitory **connections**" (M. BODEN, 1990, p.124).

This author explains: "One unit modifies another's **activity** to different degrees, dependent on the relevant connection-weight (expressed as a number between plus-one and minus-one). The details of these weight **changes** are governed by differential equations, like those used in physics. A concept is represented as a stable **activity-pattern** across the entire system".

"In **networks** that can learn, the connection weights are continually adjusted to maximize the probability of reaching **equilibrium**. Connections used often are strengthened, and if two units are activated simultaneously, then connection weights are adjusted to make this more likely in the future" (Ibid).

Moreover: "The larger the **network**, and the more distinct the **patterns**, the more **associations** can be learnt" (Ibid).

→ **Algorithm (Back propagation)**

0621

CONNECTIONS (A Classification of)^{1) - 2)}

I. BLAUBERG, V. SADOVSKY and E. YUDIN propose the following classification of the different types of connections in systems:

"1. **Interaction** connections, further subdivided into connections of **properties** (these are registered, e.g. in the physical formulas of the type $p_v = \text{const}$) and connections of **objects** (e.g. humoral connections, connections of the predator-prey type in biology, connections between separate neurons in neuron-psychic processes).

A special type of **interaction** connections are those between separate subjects-individuals, and between human collectives or social systems...

...Within this type one may distinguish co-operative and conflicting connections

2. Connections of **generation**, or genetic ones, in which one **object** appears as the **agent** causing the existence of another one...

3. **Transformation** connections, further subdivided into:

a) transformation connections realized through a certain **object** which conditions this **transformation** or sharply intensifies it (such is the function of chemical catalysts).

b) **transformation** connections realized through direct **interaction** of two or more **objects**, in (and due to) which the **objects**, singly or jointly pass from one **state** to another (such is for example, the **interaction of organism and environment** in the **process** of forming the species).

4. Connections of **structure** (frequently called structural connections). Their nature is illustrated clearly enough by chemical bonds.

5. Connections of **functioning**... the common feature of these types is that **objects** unified by a connection of functioning jointly perform a definite **function**.

6. Connections of **development** which may be regarded... as a modification of functional **state** connections, the difference lying in that the **process of development** is essentially distinct from a simple change of **states** and therefore requires additional characteristics.

7. Connections of **control**, which, depending on their concrete type, may form a **variety** of either functional connections or of those of development" (1977, p.142-144).

As any classification in general, this one is tentative and could be ordered differently as, in the authors words it "exhibits an extreme diversity of **meanings** given to the "connection" **concept**" (p. 144).

A comparison with **connection modes** shows that, even in structural connections only, the diversity is significative.

Moreover any connection implies in principle an **interaction**, thus the first class includes the other six ones, even if the structural connections may in some cases appear to be a "fossilized" residue: petrified wood is an interesting example.

0622

CONNECTIONS RIGIDITY^{1) - 2)}

Many **complex systems** are characterized by "rigidly fixed connections between all their **links**, the presence or **function** of each of which is a sine qua non of the functioning of the whole system" (I.V. BLAUBERG, V. SADOVSKY & E.G. YUDIN, 1977, p.216).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The authors give the following example: "The central nervous system, the blood circulation system, the digestive system, the excretory system, etc., are rigidly connected and complement each other in our **organism**. Each of them is necessary and cannot be replaced by another. **Structures** of this type can greatly increase the **level of organization** of systems as compared to the **organization** of the individual **links** constituting them. But at the same time these systems are much less flexible and capable of restructuring than "**corpuscular**" systems" (Ibid).

The "corpuscular" system concept has been proposed by A. MALINOWSKY (see BLAUBERG et al, Bibliography) and is somewhat akin to the **composite system** introduced in this encyclopedia.

0623

CONNECTIVE SYSTEM^{1) - 2)}

A system made of an important number of simple interconnected units ("neurons").

Each unit receives an excitatory or inhibitory **activity** (or both) which, when reaching some **threshold**, produces a change of **state**. (after J. HORGAN, 1993, p.370).

We should be careful in the use of our vocabulary. Multiple electronic interconnections are most probably not exactly equivalent to biological neurons, if only for the inexistence of biochemical **processes of transmission of flows** in the case of so-called electronic "neurons".

Another important aspect is the highly **parallelism** in such a system: numerous local **activities** occur simultaneously in different zones of the system without producing instantaneously global **interactions** in the **net**. Any excitation or inhibition get transmitted with some **delay**, even if very short.

The global **behavior** of such a system is deterministic in a general sense, but it perfectly admits **simultaneous** and more or less **aleatory behavior**, locally, within the **limits** of the **determinism of the whole**.

Besides, such a type of **net** can show a considerable **endogenous activity**, but must necessarily receive **stimuli** from its **environment**. Moreover its activity probably make sense only if it results in some **action** on this same **environment**.

0624

CONNECTIVITY^{1) - 2)}

1. "A measure of the degree of connectedness of a system" (W.R. ASHBY & M.R. GARDNER, 1970, in ASHBY, 1981, p.85-87).

This definition is very close to T.F.H. ALLEN and T.B. STARR's definition of **connectance**.

ALLEN and STARR state that "connectance": "... is usually expressed as a percentage: the percentage of nonzero **interaction** terms as a percentage of all possible **interaction** terms, reasonable or otherwise, between the **components** of a system" (1982, p.264).

Systemics, as a **transdisciplinary methodology** of **models**, offers a high degree of connectivity, allowing for example for satisfactory links of biology and psychology within social theory (P. HEJL, 1985, p.112).

2. The global character of a **network** or system whose **elements** are interrelated to some defined degree.

Composite systems have a very low degree of connectivity - which anyhow is sufficient to subsume some collective and more or less **periodical behavior**, as for example **avalanches**. However, strong **integration** is the result of a higher degree of connectivity.

ASHBY expressed the idea that a system should have a minimum of connectivity (i.e. must be more or less "joined") if it is to perform some definite **functions**. However, an excess of connectivity (in too "strongly joined" systems) leads to behavioral **rigidity** and loss of **adaptiveness**.

St. KAUFFMAN distinguishes "solid", "liquid" or "gaseous" **phases** in **networks**, corresponding to the more or less numerous presence of what he calls "**frozen cores**". (1992, p.67). This can be considered as equivalent to a measure of connectivity.

Connectivity can be easily modeled by **graphs**, which may represent local connectivities of some **elements** and more global ones between these local **clusters**. It is a fine way to obtain a visual understanding of a **network**. (see for instance S. KAUFFMAN, 1993, p.420 and 490). This author also study the "connectivity properties of random graphs (which) exhibit **phase transitions**" (p.307-10).

3. In the formal **model** of a system, the property which makes possible for the **effects** to be transmitted throughout the system (R. RODRIGUEZ ULLOA, 1994, p.136)

The author states: "Connectivity can be physical as for ex. in a system of order and delivery processing, or be an **information flow** (verbal), or a flow of **energy** or influences (Ibid).

0625

CONNECTOR²⁾

Any active **element** in a **network**.

Any connector normally receives and transmits **messages** (through a great **variety** of means, according to the type of **network**).

It may also be able to store **information** and to load the **messages** it transmits.

In very dense **networks**, many connectors are redundant, which allows in case of necessity for their functional substitution if they are eliminated, at least up to some limit.

In **languages**, connectors are "**signs** that combine (or separate) the meaning of two or more **signs**" (R.L. ACKOFF & F.E. EMERY, 1972, p.175). Examples are the words "and, or, plus, minus" or their mathematical equivalents.

→ **Communication; Small world**

0626

CONNEXITY²⁾

"The **relation** of two **parts** without the mediation of a third **part**. Non-connectivity is the absence of this **relation**" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.32).

These authors give the following example: "... the skin and seeds of an apple are non-connected. (On the contrary) three grains of sand (directly in contact) are connected (Ibid).

Connexity supposes thus the contact, *but not necessarily any interaction*.

0627

CONNOTATION¹⁾³⁾

→ **Denotation (Objective) and Connotation**

0628

CONSCIOUSNESS^{3) - 4)}

The state of a **living system** who perceives (is aware of) his/her own inside **knowledge** of inside or outside **phenomena** and possesses the ability to formulate it for him/herself and for **communication** with others.

Many definitions have been given of consciousness, probably because the subject is so difficult to grasp. The given definition has no pretense to be the only possible, nor even to be a very satisfactory one. In any case, it implies the existence of an internal microcosm, reflecting the external macrocosm and the **perception** of the difference between both.

R. FISCHER describe consciousness as "... narrative self-awareness" (1992, p.230).

G. PASK has been quite more specific: "A **process** is potentially conscious if it is organizationally closed, informationally open, and if **information** is transferred across **distinctions** that are computed as required to permit the execution of the **process**" (1979, p.214).

E. SCHWARZ indicates the three following attributes of consciousness:

"1. Existence manifested and felt in **space** and **time** through the **dialogue** between the **object** (the actual status of the system) and the **image** of this status in the (conscious being);

"2. **Self-knowledge**, as outcome of the **self-referential dialogue**;

"3. **Autogenesis**: self-production of its own **rules**, which means increase of **autonomy**" (1992, p.763).

This last point is very close to P. VENDRYES **concept of autonomy**.

B. RUSSELL gave of consciousness the curious following **description**: "The belief that makes us feel that the **image** is a **sign** of something else than itself" (1926, as quoted by J.P. CHANGEUX, 1992, p.709).

Consciousness seems however to depend basically of the capacity of **self-description**. H. MATURANA (as quoted by R. FISCHER) states: "... if an **organism** can generate a communicable **description** of its **interactions** and interact with the communicable **description**, the **process** can, in principle, be carried out in a potentially infinite recursive manner, and the **organism** becomes an **observer**. It can describe its **interactions** and communicate its **description** to others or to itself, and through the very same **process** it can describe itself describing itself" (MATURANA, 1979, in R. FISCHER, 1976, p.32).

H. Harry KLOPF writes: "Consciousness involves an awareness of self and is therefore an **emerging** property of **brains**, a property that is acquired as experience and **learning** provide increasing **information** with which to define the self, the **environment** and their **relationship**. In accordance with this definition, newborn infants are conscious only to a slight degree, if at all. (We can speak of degrees of consciousness just as we can speak of degrees of clarity of definition of the self and the **environment**, etc.)."

The author makes another important observation: "There has been a tendency in the past to confuse responsiveness in **living systems** with consciousness" (1972, p.37).

I. ALEKSANDER in turn states: "Consciousness is very heavily dependent on having a **learning** system that can represent the world more or less as it is. **A.I.** has always tried to do the **representation** at a **symbolic level** – so it has lost mental imagery, which seems to me to be the crux of consciousness" (Quoted by C. DAVIDSON, 1993, p.25).

K. BAUSCH speaks of consciousness as "embodied **awareness**". This implies that awareness can (but won't in all cases) **trigger** some **behavior**. This depends on the already constructed **frames of references**. In human beings, these include existing rational evaluations, but also **values** and **norms**, which do not necessarily have a rational foundation.

The effects of quite variable **levels** of consciousness in many different individuals and their resulting more or less coordinated and conscious **action**, is quite a difficult subject.

There seems to be now a growing **consensus** that consciousness is a complex emergent **process** in man, that results of the progressive **resonance** or **synchronization** between the thalamus and different **parts** of the **cerebral cortex** (A. CLERREMANS, 2000, p.83).

→ **Brain; Evolutionary and planetary consciousness**

0629

CONSCIOUSNESS (Economy in) ³⁾

G. BATESON observes that "... it is not conceivably possible for any system to be totally conscious" and "... every next step in the approach to total consciousness will involve a great increase in the (**brain**) circuitry required. It follows that all **organisms** must be content with rather little consciousness and that if consciousness has any useful **functions** whatever (which has never been demonstrated but is probably true), then *economy* in consciousness will be of the first importance. No **organism** can afford to be conscious of matters which it could deal with at unconscious **levels**" (1967, p.116).

This is obviously why our **brain** constructs first physiological, next behavioral and finally mental **algorithms**.

The necessity for economy in consciousness has been neatly epitomized by the Argentine writer J.L. BORGES in his fascinating short story "Funes, el memorioso", in which he recounts the case of a man who recorded the least small details that he observed and became thus totally unable to think and to act.

0630

CONSCIOUSNESS (Evolutionary and Planetary) ¹⁾⁴⁾

K. BAUSCH synthesizes as follows B.H. BANATHY's views on the subject. BANATHY "distinguishes between two kinds of consciousness which coexist at the individual and the societal level". Before going further it should be useful to give some thoughts to the existence and nature of that societal level (see Observer (Collective))

According to BANATHY: "the self-reflective consciousness contemplates "what is and creates an **image** of the self, the world around the self, and one's **role** in the world"

Possibly BANATHY's optimism should be put in perspective by a skeptical comment of A. EINSTEIN: "Der Horizont vieler Menschen ist ein Kreis mit Radius null-und das nennen sie ihrer Standpunkt"(The horizon of many people is a circle of zero radius- and they call this their viewpoint")

BANATHY follows on: "The creative consciousness focuses on "what should be". Here a second question mark appears: On the base of which criteria do we define (personally and in groups) "what should be". And what happens if no common criteria are accepted? and "...creates a guiding evolutionary vision of the desired future"...

As to the "planetary consciousness which involves the knowing and feeling of the vital interdependence and essential oneness of humankind, and the conscious adoption of the ethics and ethos that entails", it is of course probably the basic condition for planetary **survival**. However it remains to be seen if and

when this "knowing and feeling" could be achieved in a sufficient majority of the planet's inhabitants (in order to transform any utopia in a workable reality)

Moreover that "knowing" is impossible without a much deeper understanding of the deep causes of the woeful present **situation** of mankind. Such understanding can be much enhanced by the use of systemic-cybernetic **concepts**, **models** and **tools**, including in it a better **awareness** of the conditions of our own consciousness.

Finally adequate thinking (i.e. coherent, not self contradictory, wide embracing and open to progressive **adaptiveness**) seems to be the necessary bedrock for a responsible management of the issues at stake.

0631

CONSENSUS ^{1) - 4)}

A common opinion acquired by a **group** of persons after examination of the **elements** of a **situation** or problem and discussion of their **meaning**.

Consensus implies a way to acquire it. It results from **recursive** and mutually transmitted experiences on the same **objects** by different individuals, producing results that are considered similar by the participants. This is possible only if they share a sufficiently common perceptual and conceptual **background**.

G. PASK states: "... just because of our human limitations there is advantage to be gained if a **group** of **observers**, anxious to make the same sort of **predictions**, communicate with one another and in place of many private **images**, built up one commonly understood **abstraction** (such as the hypothetico-deductive **structure** of science). This will be a public **image** of the world within which all **observations** are assimilable and in terms of which **behavioral predictions** are made" (1961, p.22).

Consensus is the unavoidable condition for common **action**. However, it tends in many cases to lead to sclerosed stereotypes whose discussion is not anymore allowed. In some cases kinds of pseudo-consensus can be even hammered out and forcefully imposed: A famous historic case has been the so-called MITCHOURINE – LYSENKO theory of natural **selection** in the former Soviet Union during the fifties.

Genuine **creativity** can be easily stifled if consensus is submitted to excessively limiting **constraints** within an **organization** or culture.

Insufficiently informed consensus leads to what J. WARFIELD calls "**underconceptualization**", or to G.de ZEEUW's **invisibility**.

This danger is also implicitly emphasized by G. PASK: "An **observer** who subscribes to the plan, must limit himself to **observations** that are mutually intelligible and which can be assimilated" (Ibid).

G. VICKERS observed, from another **view-point**, that consensus reaching is a strenuous problem, because of "... the delays inherent in the **processes** of generating a sufficiently shared view of the **situation**, a sufficient consensus on the course to pursue, and sufficient common **action** to achieve it" (1967, p.62).

He notes that all these "... are collective **processes**, mediated by **communication**" (Ibid).

The betterment of **communication processes** and of techniques of **co-participative design** (**FUSCHL Group**) or **Generic Design** (J. WARFIELD) are thus generally paramount in order to obtain well- founded consensus in due time.

M. MARUYAMA contributes some curious psycho-sociological angles: "Consensus is an **homogenist**-type notion, which does not require disadvantage compensation" (1994, p.41). **Homogenist mindscapes** include as *natural* the disciplined acceptance of consensus. However MARUYAMA observes that this is not the case in all cultures, since some consider, on the contrary, that the person disadvantaged by consensus is entitled to an immediate compensation (in the Navajo-type **decision process**) or a delayed one (in Indonesian or Japanese culture).

0632

CONSENSUS AND COMPLEXITY UNDERSTANDING ^{1) - 4)}

Stafford BEER writes:

Science offers the means:

- to measure and manipulate **complexity** through mathematics
- to design **complex systems** through **general systems theory**
- to devise viable **organizations** through **cybernetics**
- to work **effectively** with people through behavioral science
- to apply all this to practical affairs through **operational research**⁴⁾.

The **knowledge** and the skills exist, but... "**Society** proceeds instead by **consensus**... The **consensus** simplifies, distorts and makes trivial the real problems of **complexification** which are inherently too difficult for all to understand.

"Thus we come to manage an oversimplified **model** of the world that exists only in the mind of the consensus, instead of the real world out there.

"This mismatch lies at the root of our incompetence" (1976, p.381/2).

Consensus is a *neutral* tool in itself. While it is the only practical way to reach common **understanding** in human systems and thus to be able to insure **autopoiesis** or innovation in them, it does not by itself guarantee satisfactory results: **consensus** may be disastrous,

since the needs of a **nonlinear complex system** are frequently **counter-intuitive** and conflictive with common sense (generally addict to **linear** ways of thought).

0633

CONSENSUS AND CONSENSUALITY ^{3) - 4)}

Following R. HARNDEN: "With respect to a **constitutive ontology** as proposed by Humberto MATURANA and based on a refined physio-psychology of **perception** and conceptualization, consensuality is about shifting currents of discourse and **understanding** in the present they realize.

"This is not the same as "consensus", which implies transcending such shifting currents in order to secure some sort of "**meta**" vantage and be able to pronounce this the "**norm**" or "average" (as agreement)" (1990, p.298).

In other words, consensuality is a psycho-social **process**, whose result is consensus, a stable **evaluation**, which may of course be reviewed at any moment by reversing to the consensuality **process**.

Consensuality protects human groups from conceptual sclerosis and their **organizations** from blockage.

However, it would be excessive to admit that any scientific theory or **model** can be refuted (or falsified in Popper's terminology) simply by some new psycho-social consensus. In AULIN's words "NEWTON was never refuted by EINSTEIN" (1987, p.76): There is "something" in the real world that, at some **scale** and within defined conditions, endows some **models** with a bedrock **stability** that no shift of consensus could alter. After all, classical gravitation calculus is what permitted the successful steering of the PIONEER and VOYAGER probes, **three bodies problem** notwithstanding.

0634

CONSENSUS METHODOLOGIES ¹⁾⁴⁾

Various authors coincide on the need of creating consensus among people who may hold different and even divergent views about **issues** that are of concern to them (knowingly or not).

The first step should be to establish a honest and as complete as possible list of **stakeholders**, including probable future ones in accordance with the also probable developments of the **situation**, or as a result of the **decisions** to be made, and the **actions** to be furthered (MITROFF & LINSTONE, 1993)

Thereafter, it is absolutely essential to avoid **blindspots** and **underconceptualization** about the nature and characteristics of the issue or situation (J. WARFIELD, 1989 a, 1994b)

And of course, no consensus can be reached (and maintained in an evolving way) without free and widely open exchanges of opinions among the stakeholders (G. PASK, 1975, 1976;

J. WARFIELD, 1994b) In order to promote these exchanges, B.H. BANATHY organized and developed the **FUSCHL** and the **ASILOMAR Conversations**, as practical training group activities.

→ **Conversation**; **Generic design science**; **Group technique (Nominal)**; **Design (Co-participative)**; **Design methodology (Systemic)**

0635

CONSERVATION LAW ^{2) - 5)}

The **first law of thermodynamics**, which prescribes that in an **isolated system**, the quantity of **energy** neither increases or decreases with **time**.

Two caveats are of great importance.

First, the law is frequently enounced as referring to **closed systems**. This introduces an **ambiguity** in relation to the possibility of observing the system. (An **isolated system**, without **inputs** or **outputs** would be unobservable: it is in fact a pure **abstract model** wherein "closed" means "isolated").

Secondly, this law is strictly quantitative: it says nothing about the *quality* of the **energy**.(- see **2nd law of thermodynamics**).

0636

CONSILIENCE ²⁾

The establishment of **consistency** among explanations of different **phenomena**

E. WILSON writes: "The explanations of different phenomena most likely to survive are those that can be connected and proved consistent with one another" (1998, p.6)

This is a social aspect of scientific **knowledge**, as the **consistency** must be established and recognized within the frame of accepted **criteria of relevance** and adequacy in some organized body of **knowledge**.

0637

CONSISTENCY ^{2) - 4)}

Character of a system devoid of any internal contradiction.

In J.L. CASTI words: "We... call the system consistent if a statement S and its negation are not both theorems of the system" (1994, p.139). As noted by CASTI, the consistency condition is closely related to **GÖDEL's Incompleteness theorem**: "Construct an arithmetical statement asserting that "arithmetic is consistent". Prove that this arithmetical statement is not provable, thus showing that arithmetic as a *formal system* is too weak to prove its own consistency", is a significant step in GÖDEL's proof (p.142).

The concept has also been discussed by M. MESAROVIC, on the base of three, interrelated **sets of systems inputs and outputs**:

In short, consistency may not be compatible with completeness.

It has been observed that "when a group of **models**, each of them internally consistent, is aggregated into a single composite model, there is no assurance of conservation of overall consistency" (J. WARFIELD, after G. FRIEDMAN-pers. comm.)

This possible lack of **compatibility** results of the fact that some specific model may well ignore **constraints** that are taken into account in another model when connected, implicit contradictions may emerge.

F. HARARY enounced and demonstrated in terms of **Boolean algebra** a "Theorem of Model consistency" stating the conditions in which consistency is conserved (1965)

- the **set** of acceptable **inputs**
- the **set** of undesirable **outputs**
- the **set** of desirable **outputs**

No consistent system can produce at the same time desirable and undesirable **outputs**. (A curious consequence is that nearly all of our human systems are inconsistent...).

MESAROVIC enounced the following theorem: "A system for which the **set** of undesirable **outputs** W and the **set** of acceptable inputs X' are specified is either inconsistent (contradictory) or incomplete" (1968, p.367-71).

There is anyhow some doubt that *any* system can be devoid of some internal contradictions. According to H.G. BURGER, who created the concept of **agonometry**, consistency may be only a **strain**, not an attainment (1967, p.221).

G. BROEKSTRA observes that the rationality of **equilibrium** in human **organizations** led to the belief: "... that **fluctuations** in the form of misfits, inconsistencies, **paradoxes** or contradictions, had to be **dampened** or suppressed... driving an **organization** towards a particular **stable attractor state** (configuration). However, although a tight **fit** may lead temporarily to excellence... paradoxically, in the long run, **fit** may lead to failure" (1993, p.76).

BROEKSTRA understands that consistency should "... be reconceptualized in terms of the **concept** of **autopoiesis**, or rather, for **social systems**, as a case of **organizational closure**" (p.78).

In short, **resilience** is better than strait-jacket consistency for the survival of any system.

→ **Incompatibility (Principle of)**

0638

CONSTANCY²⁾

The unchanging **level** of some **variable** or character of some **subsystem** for a **time**.

ASHBY explains: "If some of the **variables** or **subsystems** are constant for a **time**, than during that **time** the **connections** through them are reduced *functionally* to zero, and the effect is as if the **connexions** had been severed in some material way during that **time**... Thus a **whole**, connected system may, if a sufficient

proportion of its **variables** go constant, be temporarily equivalent to a **set** of unconnected **subsystems**. Constancies, in other words, can cut a system to pieces" (1960, p.169).

This is one of these original, stimulating... and somewhat paradoxical ideas of ASHBY. Of course, a *dosis* of constancy, let us say for example of **structural** constancy in our skeleton, is obviously helpful. But arthrosis would not be.

0639

CONSTRAINT^{1) - 2)}

"A limitation or restriction imposed upon a system or a **sub-system** that curtails **resources** or **operations**" (Adopted from B. BANATHY, 1973, p.85).

More specifically, constraints limit the possibilities of **interactions** between **elements** or **subsystems**. They also limit the **interactions** of the system with its **environment**.

In a more formal way, W. ROSS ASHBY, who introduced the concept, defines it as follows: "A relation between two **sets**, (occurring) when the **variety** that exists under one condition is less than the **variety** that exists under another" (1958, p.127).

ASHBY gives the example of the traffic lights: with three different colours and two different **states** (lit, unlit) for each one, eight **combinations** are possible. However, only four are used: Red and green are not compatible simultaneously; two of the three lights may always be lit or unlit simultaneously; all the three lights cannot be used simultaneously (the **message** would be self-contradictory); and when all three are unlit, there is no **message**. Thus, constraints imply restrictive **rules**. For simple cases, this is very clearly described in a **matrix**.

As a result, when all the possible **combinations** or **interrelations** are not used or admitted, an **observer** should look for constraints.

J. BRUNET writes: "...the **set** of the **constraints** has the effect of reducing the number of **freedom degrees** associated to a system, therefore to diminish its **variety level** and, thus its **entropy**".

"Within the frame of the 2nd. postulate (of **thermodynamics**), the **set** of the constraints appears by means of the **invariants** to which the global system is submitted; these **invariants** are associated to the great law of **conservation** in nature (mass, **energy conservation**)" (1987, p.21).

Considering the gigantic **variety** that would result from the unrestricted **set** of all the possible **interrelations** between the **components** of any **complex system**, its internal **flows** of **information**, **energy** and **matter** would become clogged and blocked if no constraints should exist.

Thus, as stated by L.J. KOHOUT and B.R. GAINES, constraints "... limit the unwanted or the dangerous **interactions** which would otherwise destroy the most essential **functions** and characteristic features of a system" (1976, p.18).

Constraints are mostly reciprocal, be it between the system and its **environment** or among **sub-systems**, but they may also be **hierarchical**, as for example in the case of the constraints imposed by **regulators** on the regulated **variables**.

As observed by F. HEYLIGHEN, constraints have an **evolutive** or historical origin: "... the system may simply be the result of a natural **selection**, where unstable **configurations** have been eliminated so that only a restricted or constrained **set** of **configurations** remains. The **concept** of an "attractor" as a region in **state space** that a system can enter but not leave, exemplifies such a spontaneously arising constraint" (pers. comm. p.10).

Of course, constraints are also learned, be it through evolutive **selection**, or individual **activity**, or as a computational technique ("multiple constraint-satisfaction"), within the limits of **organizational closure**.

In fact, learning consists of, and implies the acquisition of constraints. In M. BODEN's words: "A **connectionist network** trying to understand an **analogy** can consider many different constraints in **parallel**, and settle on the best available match even though this match may be somewhat flawed (and, by hypothesis, is never perfect).

A system in which every **element** should be connected with every other one, would be at the same time totally constrained and completely undefined, i.e. would have no **heterogenety**, no **structures** and no differentiated specific **functions**. It would indeed be no system at all. Constraints are thus an absolute necessity for systems.

Paradoxically, however, the same situation would result if no **interconnections** at all should exist.

In synthesis, constraints in systems, when not excessive and stiffling, are **freedom-limiting**, but **order-creative**. They constitute **algorithms** for some productive ways to act. Striking examples are classical, or dodecaphonic harmony, or the hindu raga-style.

M. BODEN even states: "...far from being the antithesis of **creativity**, constraints on thinking are what make it possible" (1990, p.82).

The constraints characterizing a system are potentially present at the time of its **autogenesis**, for reasons and in ways that are not yet very well understood. They become actualized through the **process** of **morphogenesis** and lead to **autopoiesis** through **organizational closure**, but this results also from the system

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

interactions with its **environment**... But, the more the system closes on itself, the less it remains able to adapt to a more global, and changing **environment**.

ASHBY, who much developed the constraint concept, states: "...the **organism** commonly faces a world that repeat itself, that is **consistent** to some degree in obeying laws, that is not wholly **chaotic**. The greater the degree of constraint, the more can the adapting **organism** specialise against the particular form of **environment** that do occur" (1960, p.139).

ASHBY also observed: "The constraint is thus a *relation* between **observer** and thing: the properties of any particular constraint will depend on both the real thing and on the *observer*. It follows that a substantial part of the theory of **organization** will be concerned with *properties that are not intrinsic in the thing but are relational between observer and thing*" (1968, p.109).

0640

CONSTRAINT ANALYSIS ²⁾

"A formal method for decomposing the constraint within a **whole** system into several constraints within **subsets** of its **variables**, (i.e., of an **ordinality** lower than the original) so that the latter fully account for the former" (K. KRIPPENDORFF, 1986, p.16).

KRIPPENDORFF claims that constraint analysis "thereby reveals the **component structure** of an observed system" (Ibid). The method is however **reductionist** and one should take care unless, by ignoring and severing **interactions** between local or specific constraints, something essential to the global constraint could disappear.

The method is closely related to KLIR's "**re-constructability analysis**".

0641

CONSTRAINT (Dynamical) ²⁾

"A **selection criterion** that determines which of the possible **state transitions** corresponding to different **operators** will actually take place" (F. HEYLIGHEN, 1990a, p.426).

"Dynamical constraints usually have the form of either:

- 1) differential (or difference) equations, relating the predicted **state transition** (time derivate of the **state**) to the present **state**
- 2) **conservation** principles, stating that a certain global property of the system (e.g. **energy**) must be conserved during the **transition**, or
- 3) **variation** or **optimization**. principles, stating that the **transition** will occur that minimizes (or maximizes) a certain **function** of the **transition parameters** (Ibid).

"A dynamical constraint corresponds to a **distinction** between an allowed **state transition** and an impossible one" (Ibid, p.427).

0642

CONSTRAINT (Emerging) ²⁾

A constraint produced by the progressive interplay of the **elements** of a system during its **morphogenesis**.

Such constraints are, for example, new **rules** of interaction (or their actualization, if they already existed potentially), new **communication** lines, new roles for the **elements**.

Of course, once established these **rules**, roles and lines, they tend to become permanent and obligatory and, consequently, to restrict other potentialities, or even to annulate them.

Emergence of constraints is an aspect of **organizational closure**, and in some sense, of the **algorithmization** of the system. It is a very significative aspect of instruction or training, as well as of **structuration**.

0643

CONSTRAINT (Hierarchical) ¹⁾

The **control** exerted by one **holon** over another lower in a **hierarchy**" (T.F.H. ALLEN & T.B. STARR, 1982, p.265).

These authors state: "The constraining **holon** behaves more slowly than the constrained **holon**. The constraining **holon** influences more than it is influenced in the act of constraint" (p.265).

The "constraining **holon**" is generally a **metacontrol** or **metasystem**, in J.van GIGCH sense.

0644

CONSTRAINT (Second order) ²⁾

A constraint imposed on the variation of constraints.

F. HEYLIGHEN, who introduces this **concept**, applies it to the **emergence** of systems (in the sense of TURCHIN's **Meta System Transition**). He writes: "We may conceive the **emergence** of such a **metasystem** in the following way. Assume that a system has insufficient internal **variety** to maintain itself in its given **environment**, and that it can only reach the adequate **configurations** by changing its defining constraint. If the constraint changes in a relatively slow, continuous way, we might say that the system survives the **changes**, even though its identity has changed in the **process**.

(Comp. note: it would seem in this case that the system only has **accommodated** or **adapted** itself). "But the variation of the constraint itself undergoes **selection**, and that means that most likely an eventual stable **configuration** of second-order variations will be reached, defining a second-order constraint. This defines a new **metasystem**.

"When this **process** is combined with the **process** of a **supersystem transition** we will find that several systems undergoing second order variations collectively develop an overall constraint on their mutual **variations**. Here we

come back to TURCHIN's original structural characterization of a **metasystem transition**, where a number of **subsystems** are integrated, under the **control** of a higher order **mechanism** of constrained **variation**" (pers. comm., p.16).

We have, in this way and simultaneously, the opening of new possibilities of **variety** creation and their ordering by second order constraints.

0645

CONSTRAINT THRESHOLD ²⁾

The **configuration** in **space** and the instant in **time** where and when the **behavior** of a **composite system** suddenly changes.

P. COUSSOT and J.M. PIAU comment: "When the concentration of particles increases, the median **size** of the **clusters** increases and, suddenly, beyond a defined **concentration**, a global **net** of **interactions** appears, which connects the whole sample. This is a **percolation phenomenon**.

"The fluid possesses a constraint threshold that represents the minimum constraint that must be applied to break the **net** and start a **flow**" (1993, p.1086).

The concept is of great importance for the study of **avalanches** of snow or mud, heaps of semi-viscous materials, gels, pastes and doughs, etc., where such thresholds can readily be observed.

Constraint thresholds, as a rheological effect seems however to be quite a more general type of **phenomenon** and be akin to the concepts of **catastrophe** and **bifurcation**.

It would be interesting to research possible constraint thresholds in **living** and **social systems**.

0646

CONSTRAINTS (Antagonistic) ²⁾

Constraints that are mutually constraining.

An example is the necessity to insure fast and massive transportation and the resulting growing **overcrowding** of lanes and streets. Another is the antagonism between high **multiplication rate** and **survival** of the species (as in *Dyctiostelium discoideum*... and probably in the human species).

Increase in antagonistic constraints may lead to a sudden change in global **behavior** and is possibly a significant factor in **anagenesis**. If antagonistic constraints are not to be destructive they must harmonize, i. e. enter in a compatible **interrelation**, i.e. be submitted to a higher **level regulation** or constraint, i.e. become **part** of a wider system.

0647

CONSTRAINTS (Cognitive) ^{1) - 4)}

R. ESPEJO focused the attention on the fact that: "...all viewpoints will recognize only a limited number or the possible outcomes of a

black box. But different viewpoints will recognize different numbers. Therefore, in measuring **complexity** it is always necessary to choose the appropriate viewpoints" (1988, p.141).

(Note: In concordance with St. BEER, ESPEJO uses the **black box model** as "... a shorthand for the real world" (Ibid.).)

Viewpoints are diversely affected by perceptive, cultural, social, and the resulting conceptual limitations.

Being thus constrained, the **cognition of complexity** in systems and in **situations** can never be complete. As to "appropriate" viewpoints, we are always in dire need for individual and common **criteria** if we seek **consensus**.

→ "**blindspot**", "**invisibility**" and "**under-conceptualization**".

0648

CONSTRAINTS: (Internal and external)^{1) - 2) - 3)}

Any system is submitted to two different classes of constraints, i.e. internal constraints which organize its necessary **heterogeneity**, and external ones, which result from the more or less stable or unstable conditions in its **environment**.

The internal ones are defined by the central **control subsystem** (see **stellar type system**), which ensures **autopoiesis** on the base of the formerly registered **evolutive** traits corresponding to the system's **class**. These constraints are, for example, genetic, normative, statutory through by-laws, etc...

The external constraints are the present limitations imposed upon the system by its **environment**. They may well be at variance with the historical or **evolutive** constraints already registered within the system and thus be a source of serious problems.

I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN insist rightly on the importance of this feature: "Experience shows that many complex problems of today are not solved at all or are solved incorrectly or ineffectively only because they have been wrongly formulated, because not all the essential aspects of the ...constraints imposed on its solution have been taken into account" (1977, p.262).

This is also a result of the "**isolated**" or "**closed**" system fallacy, leading to study the system only from inside, in a kind of aseptic vacuum.

0649

CONSTRAINTS (Self-generated)¹⁾²⁾

Those **constraints** imposed on the system by its own **activity**.

G. ARMALAGOS writes: "As long as a virus has an effective **mechanism** for jumping from one person to another, it can afford to kill its victims" (1998, p.25).

If it however does kill too quickly, it limits severely its own expansion: "Gruesome pathogens such as Ebola are unlikely to cause a widespread **epidemic** because they sicken and kill so quickly that victims can easily be identified and isolated" (Ibid., p.24)

Historically, the same effect operated in a different way: After the "Black death" pest **pandemics** in Europe (1347-1352), successive resurgences of the disease killed less and less people, probably at least in part because the survivors of former epidemics offered a growing resistance to it and somehow transmitted it to their descendants.

The growing **resistance** of pests and pathogens to a number of our new 20th. Century medicines is probably another example.

More generally, new collective **constraints** emerge from the massive success of some innovation. The growing traffic problems resulting from the evermore massive use of cars is an example. This corresponds to J.van GIGCH's **side** or **spill-over effects**, or to the French sociologist R. BOUDON's perverse effects.

Such self-generated constraints are due to multiply in our expanding **ecosystems** and **sociosystems**, under the pressure of accelerating quantitative **growth**.

0650

CONSTRUCT³⁾

A mental way of ordering a number of **elements, observations** or **data** in some manner coherent with previously structured **knowledge**.

In E.von GLASERSFELD words: "... constructs... are results of mental **operations**" (1988, p.4).

This does not mean that constructs are independent from what we call "reality", but only that they are something different from it. This is thus no idealist Berkeleyan proposition.

The **concept** of construct starts from the understanding that a simple incoherent collection of any kind of **elements, observations** or **data** would be useless for any **purpose** and that the **observer** is necessarily ordering them somehow. This "somehow" depends on an **organizational closure process**, i.e. of the internal physiological, psychical and mental (seemingly in that order) **organization** of the **observer**.

The physiological part has to see with the specific ways of sensorial **perception**, which impose by themselves **constraints** and thus, **coherence** (J.J. GIBSON, 1986). The **process** proceeds through psychical and mental ordering in the endocrine and nervous **subsystems**, which again implies specific ways of ordering.

So-called "**facts**" are elemental constructs, corresponding to something "out there". **Memories**, hypotheses, **algorithms**, **models**, theories, **languages**, etc... are more elaborated constructs.

Constructs gain social value through **conversation** and **consensus**. They are always **falsifiable** in POPPER's sense.

→ "**Ontological skepticism**".

0651

CONSTRUCTIONISM¹⁾

According to E.von GLASERSFELD, this term has been "invented by K. GERGEN to distinguish his way of thinking from that of other constructivists" (1999, p. 11)

According to GERGEN "The constructionist is centrally concerned with such matters as negotiation, **cooperation**, **conflict**, rhetoric, **ritual**, **roles**, special **scenarios**, and the like, but avoids psychological explorations of microsocial **process**" (1995, p. 25)

Thus, constructionism seems more "**conversational**" (in PASK's way) than **autopoietic** (in von FOERSTER's and MATURANA's way) somewhat at variance with **constructivism**.

Anyhow, both concepts are closely related and, as in the case of the egg and hen, it is quite difficult to distinguish what came first.

Indeed, von GLASERSFELD concludes: "What speakers have learned to mean always remain their own construction" (p. 16)

(See the special issue of "Cybernetics and Human knowing" 6(1) 1999 on "Radical constructivism in education" for more on this subject.

0652

CONSTRUCTIVISM^{1) - 3) - 4)}

A theory of **knowledge** and a **methodology** for its acquisition based on a better **understanding** of our ways of **perception** and interpretation of reality.

J. WARFIELD states that constructivism embodies the following beliefs: "a) a **universe** exists, which includes human beings capable of observing small **parts** of that **universe**; b) observation by the human occurs through sensory **perception**; c) The aggregate of all prior and present sensory **perceptions** is translated into **patterns** by each individual **observer**, this **aggregate** constituting the "virtual world" of that **observer**" (1994, p.63).

According to K. KRIPPENDORFF, "Constructivism is a reaction against the Gibsonian view that **knowledge** and **perception** are the result of sensation" (1986, p.15). However, GIBSON's views, while seemingly incomplete, appear as fundamentally correct: it is not possible to imagine any **perception** and **knowledge** without the use - eventually indirect - of sense organs, tuned to the physical world by eons of biological **evolution**. This is not to deny that sensations, transformed into **percepts**, finally produce **constructs**.

→ KORZYBSKI's "**structural differential**".

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

On the other hand, H.von FOERSTER (1981) insisted on the need for any living being to organize itself in such a way as to be able to maintain a stable and coherent **survival** relation with its **environment**. It would be impossible for it to recreate such internal **organization** everytime it experiments a new sensation. Should this be the case, the **survival** value would be nil.

E.von GLASERSFELD thus introduces the basic tenets of constructivism: "(the **object**) has to be produced by the **organism's** own construction regardless of whether we believe that the **concept** corresponds to a thing-in-itself that exists "out there" independent of any **organism's** experience...

"From the point of view of the experienter, there can be no **object** until he himself coordinates several experiences and thus **constructs** the **invariant concept** of the **object**" (1976, p.116).

This is quite similar to A. KORZYBSKI concept of the **process** of progressive **abstraction** (1950). We should, as a **semantic** exercise, always put the word "**object**" inbetween quote marks.

von GLASERSFELD adds: "Seen from the point of view of the developing **organism** at the beginning of his cognitive career, it makes no difference at all whether regularities, **invariances**, and **rules** "exist" in a "real" world or not, since the only place where the **organism** can find them, learn them and **know** them is in his own experience" (Ibid).

We are thus led to **ontological skepticism**, but not, of course, to ontological nihilism, nor even agnosticism. This point is thus made by G. KLIR: "To avoid any confusion, it should be emphasized that the constructivist view does not imply that the existence of the real world, independent of the human mind, is necessarily denied. This is a different issue on which constructivism remains neutral. Constructivist view is not an **ontological** view (concerned with the existence and ultimate nature of reality), but an **epistemological** view (concerned with the origin, **structure**, acquisition, and **validity of knowledge**)" (1993, p.30).

And still, according to von GLASERSFELD: "Even if we postulate a fully structured, pre-existing world, the growing **organism** can build its **representation** of that world from no other material than the proximal **data** of its experience" (Ibid., p.119).

This is in line with J. PIAGET **understanding** of construction of reality in the child. It would also be enough to add "sensorial" to "experience" in order to coordinate GIBSON's and von GLASERSFELD's views.

On the other hand, as stated also by von GLASERSFELD, what we consider as "objective" arises from the confirmation by others from our own experience. It is the intersubjective repetition from experiences which delivers

the surer guarantee about the "objective" reality (1991, p.33). As a result, as resumed by M.C. JACKSON: "von GLASERSFELD further believes that, since one has to hypothesize "others", whose **understanding** and **actions** are close to one's own, to provide the highest forms of confirmation of the reality constructed (enough to call it "objective"), it is possible to postulate a constructivist ethics" (1988, p.120).

M.C.LE DUC proposes the following logical principles of constructivism:

"1. The principle of **recursion**:... the mental world organises the concrete world by organising itself

"2. The principle of dialogics: Sometimes **truth** is a dynamic **process** of two opposing and complementary mental **structures**.

"3. The principle of **truth by action**. VICO put it best (verum ipsum factum). A mental **construct** is true if it has been proved effective in **action** and effective action elicits **truth**" (1992, p.920).

As a result, radical constructivism is to be a theory of **knowledge**, but not a theory of being ("Sein").

Constructivism (Radical)

E.von GLASERSFELD, the main proponent of constructivism, explains as follows this extreme posture: "The substitution of the **concept** of **fit** (and its dynamic corollary, **viability**) for the traditional **concept** of **truth** as a matching, **isomorphic**, or **iconic representation** of **reality**, is the central feature of the **theory of knowledge** I have called Radical Constructivism" (1988, p.77-8).

In a recent reconsideration E.von GLASERSFELD wrote: "Constructivism is an **epistemological model** and can no more be empirically refuted than LEIBNIZ's Monadology, NICHOLAS of CUSA's theory of "docta ignorancia", or any other theory of knowing. They are conceptual **networks** built on **assumptions** which one

may or may not like; they have no **truth** value; what matters in their internal **coherence** and whether we find them useful"(as quoted by R. GLANVILLE, 2001, p. 142)

J. MINGERS makes this point even clearer: "Constructivists tend to argue (as does von GLASERSFELD) that their's is purely an **epistemology**, concerning limits on our **knowledge** of the world, not an **ontology**, concerning what may or may not exist"(1996, p. 21)

In fact, the deep nature of the very **observers** escapes the ontological query only through a kind of basic agnosticism.

→ **Ontological skepticism**

0653

CONSTRUCTIVIST CYBERNETICS (Epistemology of)³

Second order cybernetics generally implies a re-examination of scientific **epistemology** and **methodology**. While such a revision should also include physical sciences, it is never more important and necessary than in human sciences, because these study **situations** wherein participants are thinking beings who study themselves.

Stuart UMPLEBY elaborated the following comparative table between three quite different contemporaneous approaches (1990, p.116):

see table below

0654

CONSTRUCTS (Conceptual)³

"The reconstruction of direct experience in systems of **symbols**, culminating in science" (J.S. SUTHERLAND, 1973, p.55).

J.W. SUTHERLAND admission that science is basically the culmination of a **process** of conceptual construction, based of course on **observation** on a **phenomenological level**, is noteworthy and very useful from an **epistemological** and **ontological** viewpoint.

→ **Compressibility**

Table: see entry CONSTRUCTIVIST CYBERNETICS (Epistemology of)

POPPER	KUHN	CONSTRUCTIVIST CYBERNETICS
A normative view of epistemology : how scientists should operate	A sociological view of epistemology : how scientists in fact operate	A biological view of epistemology : how the brain functions
Non-science versus science	Steady progress vs. revolutions	Realism versus constructivism
Solve the problem of induction : conjectures and refutations	Explain turmoil in original records vs. smooth progress in textbooks	Include the observer within the domain of science
How science as a picture of reality is tested and grows	How paradigms are developed and then replaced	How an individual constructs a "reality"
Scientific knowledge exists independent of human beings	Even data and experiments are interpreted	Ideas about knowledge should be rooted in neurophysiology
We can know what we know and do not know	Science is a community activity	If people accept this view, they will be more tolerant

¹general information ²methodology or model ³epistemology, ontology and semantics ⁴human sciences ⁵discipline oriented

0655

CONSTRUCTS (Synchronous)^{1) - 2) - 4)}

Any social construct must necessarily be highly **synchronous**, i.e. respect collective **coherence** in **time**. This can be easily observed in human construction of any kind of **structures**, not only material but also economical, social or political. It is however also present in the **activities** of social insects, where it corresponds to **stigmergy**, and in the progressive development of any living being, from **embryogenesis** on.

In the case of gregarious **behavior** in fish shoals, or locusts, as well as in the case of the amoeba *dictyostelium discoideum*, **synchronicity** originates in the reciprocal **perception** of visual **stimulation** (fishes) or pheromones, starting possibly with a **positive feedback** among local **groups** of individuals.

The same mechanism can be observed on a freeway at rush hours. Individual drivers experiment simultaneously various conditions: perceptive (observing what is going on), mental (understanding the **situation**), psychological (taking care), physiological (some **stress**) and physical (acting) evoked by the movements of their close neighbors in the traffic lanes. Their **interconnected reactions** gradually gain ground in all directions and finally a **global flow** appears, into which every driver becomes dynamically **channelled**.

This "case study" seems to indicate that **synchronous** constructs are one of the most basic features of **human systems**, in still more ways than in the case of other social systems.

Social constructs, when tending to permanence, are the in-making **phase** of social **constraints**.

0656

CONTENT^{1) - 2)}

"That which flows, or circulates in a system, or constitutes it" (D. Mc NEIL, 1993, p.11).

In Mc NEIL's words: "Although **form** and **function** (or their respective homologues "**structure**" and "**process**") are the two most often acknowledged aspects of systems in the literature... the most often neglected (one) is the aspect of "substance" or content" (Ibid).

This author considers that any system can be modelled as a **toroid vortex** within associated **fields**, in which contents are more or less flowing according to their **structure** or **process** nature.

0657

CONTENTION⁵⁾

In a **network** where any **element** may have access to a central **store** of **data**, a **situation** of mutual locking which impedes the normal access to the needed **information**.

This may occur in Multiple Instruction Multiple Data (MIMD) **parallel processing machines**, but it can also occur in any **communication system** working in **parallel**.

0658

CONTEXT^{1) - 2)}

1. The **environment** of a **fact**, **datum**, **situation**, word, **information**, etc... that helps its **understanding**.

2. "A **metamessage** which classifies the elementary **signal**" (G. BATESON, 1967, p.260).

A sufficient context should include the effective **interactions** that could alter the **meaning** of any registered **observation**.

G. BATESON states: "Either we must discard the notion of "context", or we retain this notion and, with it, accept the **hierarchic series** - **stimulus**, context of **stimulus**, context of context of **stimulus**, etc. This series can be spelled out in the form of a **hierarchy** of **logical types** as follows:

"**Stimulus** is an elementary **signal**, internal or external

"Context of **stimulus** is a **metamessage** which classifies the elementary **signal**.

"Context of context of **stimulus** is a **metamessage** which classifies the **metamessage**.

"And so on" (Ibid).

A kind of **recursive algorithmic** perceptual and conceptual Russian matrioshka, so to say.

0659

CONTEXT DEPENDENCE³⁾

The condition required if a **symbol** or **concept** is to acquire an extended or more precise **meaning**.

F. HEYLIGHEN writes "(a **concept**) receives its **meaning** through the whole of **associations** it has with other primitive **concepts**. Those **associations** are the result of a slow **process** of **learning** based on many experiences of contiguous occurrences of two **concepts**" (pers. com.).

Biological **information** is also **context-dependent**. The sender and the receiver alike are influenced in their **information transfer** by numerous **contingent** conditions of very varied and variable nature.

The **understanding** of this **contiguity** of **concepts** and **symbols** is, by the way, very useful for the use of the present dictionary.

0660

CONTEXT (Evolving)^{1) - 2) - 4)}

Context (**environmental** and **invironmental** as well) is not invariable. Any system must adapt repeatedly. Species **co-evolve** within **ecosystems** and through mutations provoked by various context factors; individuals learn new ways and **behaviors** as they perceive new **situations**

and societies readapt their **organization** and, in some cases, their basic beliefs and **values** under inside or outside duress.

Generally speaking, this is **co-evolution**: there could be no **evolution** out of context.

0661

CONTEXT (Internal)^{1) - 2)}

"The context into which **information** is received" (G. BATESON, 1973, p.370).

As stated by BATESON: "... **information** comes out of a context into a context" (Ibid).

A system is basically, from this viewpoint, an **entity** in which internal context is different from the outside context. This is the reason why this compiler found it necessary to introduce the concept of **invironment**.

This is also the rationale behind J. MILLER's **input and output transducers** and **decoders** and **encoders**.

0662

CONTEXT MARKER^{3) - 4)}

A **signal** which helps to give a specific **meaning** to some **percept**.

This **concept** has been introduced by G. BATESON, who gives some examples of such context markers:

" - The Pope's throne from which he makes announcements ex cathedra, which announcements are thereby endowed with a special order of **validity**.

" - The placebo, by which the doctor sets the stage for a **change** in the patient's subjective experience.

" - The shining object used by some hypnotists in inducing trance

...

" - The handshake of boxers before the fight" (1967, p.261).

0663

CONTEXT (Meaning through)³⁾

Perception is meaningless without context, because it acquires some significance only through interconnected cerebral **networks** of former **perceptions** properly interpreted and ordered, this being the inner context.

There must also be an outside context. As stated by G. BATESON: "An **organism** responds to the 'same' **stimulus** differently in different contexts, and we must therefore ask about the source of the **organism's information**" (1967, p.260).

The context thus somehow imposes **constraints** on the interpretative **code**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0664

CONTEXT NEGLECT²⁾⁽³⁾

Context neglect is a general and sure-brand recipe for unsatisfactory based research, as well as theoretical problems and the production of awful **messes**, when applied to practical **issues**.

K. PRIBRAM, for instance, writing about **learning**, as viewed by psychologists, states: "... the **set of events** in which **information** occurs, is as important a determinant of the outcome of ... **experiment** as the **information** carrying **signal** itself. And yet it is usually this context that remains unspecified, unstudied, and often hopelessly shrugged off as being impossible to study" (1969, p.194).

No **situation** or **issue** can be aseptically confined and the needed "de-confinement" is at the same time one of the most important possibilities as well as a main responsibility of **systems inquiries** through adequate context-connected **concepts** and **models**.

0665

CONTEXT OF CONTEXT³⁾

"A **meta-metamessage** which classifies the **metamessage**" (G. BATESON, 1967, p.260).

0666

CONTEXT (Relevant)³⁾

That part of the context that helps to classify the **message** (After G. BATESON, 1973, p.218).

BATESON explains how the context may reinforces or modify the **message**, for example "... place the **message** in the category of humour, **metaphor**, etc. The setting may make the **message** inappropriate. The **message** may be out of tune with the larger context, and so on. But there are limits to these modifications. The context may tell the recipient anything *about* the **message**, but it cannot ever destroy or directly contradict the latter" (Ibid).

BATESON gives an interesting example: "I was lying when I said 'The cat is on the mat'" tells the vis-a-vis nothing about the location of the cat. It tells him only something about the **reliability** of his previous **information**" (Ibid). This means that the **message** is reclassified within a different relevant context: it should not have been taken at its face-value.

Of course, while "relevant context" for **human information** and **knowledge** is a matter of **paradigms**, "without context, there is no **communication**" (p.378).

However, it seems now to be correct even in genetics and embryology, as shown by the discovery of the importance of the reciprocal positions of genes and chromosomes.

→ **Positional value**

0667

CONTEXT (Repeatable)¹⁾

As noted by G. BATESON, context is repeatable, even if not entirely repeatable, as it is evolving.

BATESON states: "Without the assumption of repeatable context (and the hypothesis that *for the organisms* which we study the sequence of experience is really somehow punctuated in this manner), it would follow that all **learning** would be of one type: namely, all would be zero **learning**" (1973, p.259).

In other words, no **adaptation** and no **evolution** would be possible, and possibly no coherent systems of any kind. Repeatability is a very general feature of the physical, the biological, the psychological, the mental and the social spheres.

0668

CONTEXT SENSITIVITY³⁾

T. BAUMGARTNER et al. state: "Systems differ in the degree and quality of their **structural sensitivity**: from the deductive systems of pure mathematics where there is a systematic effort to remove all context **dependence** in order to emphasize the underlying abstract **relationships**, to the high degree of context sensitivity and structural **dynamics of living systems**" (1976, p.34).

Low context sensibility in **models** is acquired only by suppressing the context as far as possible. However such simplifications do not lead to satisfactory results in **complex systems modelling**.

The problem of context sensibility, viewed from the **modelling** angle is now under precise focus through **chaos theory**.

0669

CONTEXT-FREE ELEMENTS^{1) - 3) - 5)}

P. DENNING writes: "The failure of **artificial intelligence** to produce **machines** with any of these capabilities (e.g. many **behaviors** that are very simple for human beings) after forty years of research is not a failure of intention. It is a failure of the rationalistic philosophy deeply rooted in Western thought. That philosophy has produced in many disciplines a search for **models** that combine context-free (meaningless) **elements** into systems governed by formal laws. Not only have **information-processing models** of **cognition** fallen short in computer science, but corresponding **models** have also fallen short in anthropology, economics, linguistics, political science, psychology and other disciplines" (1989, p.333).

Of course, no **element** is ever context-free, as it is its **interactions** with other **elements** which give it its **value**, which is modified when these **interactions** change.

This conceptual quagmire explains the problems which arised from some theoretical formulations when unduly applied in factual **situations**. A good example is the **2d law of thermodynamics** and its consequences for the irreversible disorganization of **isolated systems** (a purely abstract **concept**, scantily related to **concrete systems**). The impossibility of the existence of life, supposedly resulting from the 2d law, created awful conceptual tangles in the minds of three generations of biologists: this riddle was resolved only after BERTALANFFY's and PRIGOGINE's work.

0670

CONTEXTS (Psychological)¹⁾⁽²⁾⁽³⁾

The Greek psychiatrist and systemist N. PARISIS (Zeugma, 2000) enounces the following contextual **links** that can activate, desactivate or transform the psychological orientation ("tropos") of a person:

He writes: "**Contexts** can be in the natural **environment** reflected in the mind, or directly in the mind as in the cases of:

- **situations** of the present or the past
- stages of **human systems** intelligent development
- the **supra-systems** in which the human system belongs such as families, work environment
- human systems **relations** such as friendship, love, hate
- particular **interactions** of the moment such as quarrelling, courtship, running
- emotional states such as anger, fear, love, anxiety, depression, peacefulness, hapiness
- **theories**, beliefs, **values**
- **cultures**, myths, **religions**
- political or social **organization**
- nations"

Psychological contexts (and cultural ones) are a matter of very serious concern considering the acceleration of general transformation of mankind as well as the multiplication of interrelations among millions of people of many different origins.

→ **Conversation; Culturocentrism; Frame of reference; Perception; Transculturation**

0671

CONTEXTUAL IMPLICATION³⁾

This notion was introduced by C.S. PEIRCE and retaken by J. WARFIELD, who explains it as follows:

"Every question involves contextual implication

"In the first instance, CI refers to:

a) The linguistic demand placed on the recipient of the question

b) The hypotheses that underlie the question

"In the second instance, CI refers to:

a) The (implied) questions to which those hypotheses are possible answers, and

b) The contextual implication of the implied questions

c) The hypotheses underlying those questions

"and so on until a possible point is reached where there is no contextual implication. If such a point is reached it is in the axiomatic domain" (pers com.)

This concept is basic to any systemic **inquiry** because it helps to avoid undue simplifications. However, a **limit** must be put to the **process**, i.e. must be clearly perceived and stated.

0672

CONTIGUITY²⁾

The closeness of **elements** in **space** and/or **time**.

Patterns of **interaction** are more easily formed among **elements** which are close to each other in **space** or **time**. This is a result of the non-instantaneous **propagation** of **effects** and helps explain **phenomena** like **random** or causal **linkages**, **clustering**, local system's formation, **gestalt perception**, etc.

Applying this to **perception** S. ARIETI states: "Sense-**data** experienced together tend to be re-experienced together, if they produced one **effect** in the **organism** by the fact of being together. The **effect** in its turn connects more firmly together the sense-**data**" (1965, p.109).

However: "The mode of **operation** by contiguity, which seems at first so simple, is something which instead requires the solution, through evolutionary **mechanisms** of a difficult problem... : **response** of a **part** versus **response** to a **whole**... In normal conditions, **whole – perception** wins out and the mode of contiguity generally applies to the contiguity of the various **parts** which form differentiated **wholes**" (Ibid).

In other words, contiguity is instaurated by **re-inforcement**. Moreover, contiguity **perception** must be the cause or condition of **Gestalt** construction.

0673

CONTINGENCY³⁾

Character of an **event** depending on **chance**.

Environmental **events**, for example, are sometimes contingent, which means that the system is unable to **forecast** them, as they do not enter in any determined **process**.

As observed by St. GOULD: "Contingency is the affirmation of **control** by immediate **events** over destiny, the kingdom lost for want of a horseshoe nail"

Contingency should not be confused with **indeterminacy**. The fortuitous event does not annulate **causality**. It merely triggers it in unpredictable circumstances.

For example the deeper roots of a **conflict** and in most cases the ways it will evolve are mostly independent of the specific circumstance that started it. A good example is the

first world war, triggered but not caused by the assassination by a Serb of an Austrian archduke in Sarajevo. Causes were of a very wider and deeper scope and war could have been triggered by any other fortuitous incident (See R. ARON, 1961)...or avoided at least for some time.

Contingency strongly limits the possibility of formulating absolutely rigorous laws in social sciences and **history**, wherein controlled **experiences** are impossible and **events** never repeat in an identical way.

Contingency has to see with the relation between a system and its **environment**. It corresponds to the generally very high **variety** in the environment...and also to the high internal variety of the system. O. THYSSEN (1995, p. 16) explains LUHMANN's view on the subject: "A stable system is not a system which does not change at all, but a system which is able to maintain its identity and **performance** in spite of high contingency in the environment and the system itself.. And "contingency forces a system to relate to a rich **repertoire** of **unstable** and uncertain **states**, so that the system faces a permanent pressure to choose"

Systemics tries to reduce contingency by replacing **events** in a more general **reference frame**. In this sense, earthquakes, volcanic eruptions and hurricanes, for instance, will remain contingent until better global theories would eventually decrease their **unpredictability**.

→ **Historical determinism; Predictability**

0674

CONTINGENCY (Mutual)^{3/4)}

The reciprocal **relation** which appears when two partners of **communication**, that Luhmann calls Ego and Alter, start their **relationship**. In L. QVORTUP words: "Ego communicates, but it communicates with the other as a projection of ego, i.e. with Alter ego. Here, contingency becomes mutual, or double contingency"(1993, p. 15). It may become a kind of mirroring mirrors.

This is quite similar to G. PASK concept of **conversation**. In fact, Ego and Alter are trying to understand each other, i.e. trying to express themselves in terms understandable to the other. If any result is to be obtained, it can be only in terms of reciprocal **adjustments** of **meanings**. Or in other words, the internal **reference frame** of both experiences an **adaptation** in order to represent the other. It is a kind of experimental **construction** of a significant relationship: one must be able to interpret the other, in terms that allow for an evermore fluid exchange. It means that Ego's own reference frame must ideally reflect in an adaptable way what one perceives of Alter's reference frame.

Moreover, only if this works in a satisfactory way, can it become a sound basis for **social systems**. As a result, in LUHMANN's words (as translated and quoted by Qvortrup): "...**cognition** has to be understood as the **recursive processing** of **symbols** (however materialized) in systems which are closed through the conditions of the connectability of their **operations**" (Ibid)

Anyhow Luhmann considers "that the **social systems** cannot think". This is probably the root of all social problems: thoughtful communication is scattered in a multidinous way and "public opinion" is that self-produced and re-produced unconscious monster made of myriad of small monsters described in BÖCKLIN's engraving. The results are generally enigmatic and sometimes frightful

0675

CONTINUITY^{1/2)}

The **long-term** general **dynamic stability** of a system.

Continuity does not exclude variations, even large **scale** ones. However, in this condition, the system retains its basic identity and nature.

Continuity corresponds to the **minimum entropy production theorem** enounced by PRIGOGINE. External **constraints** and/or internal **controls** are instrumental for continuity maintenance.

0676

CONTINUOUS – DISCONTINUOUS^{2) – 3)}

To discriminate basic continuity or discontinuity in nature is one of the most difficult – and even irritative – riddle in science and philosophy. According to R. THOM, this is a metaphysical problem. Curiously enough, this mathematician who created **catastrophe theory**, a **topological** theory of discontinuities, states that "the essence of catastrophe theory is precisely to reduce apparent discontinuities to a manifestation of a slow subagent **evolution**"¹⁾ (1991, p.62). For him, "the discrete character of a **transformation** is a simplification brought about by our perceptive system" (p.63). He adds: "We are made essentially to see discontinuities. Only these are significant. For an animal, it is essential to recognize preys and to localize them" (Ibid). As a result, our nervous system is organized toward the **perception** of the apparent **objects** outlines.

This is also true in **language**: "... we *discretize* phonemes" (p.64)... in order to become able to distinguish them. All in all, THOM's arguments do not seem conclusive. We have no definitive way to decide the matter.

It is even possible that this **dichotomy** is a perceptive **artifact**, in relation to **mega-**, **macro-** and **micro-levels** of **perceptions**.

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

Systemists should remain careful when postulating continuity or discontinuity in **models** and **constructs**.

0677

CONTRACTION²⁾

Quality of an **adaptive nonlinear** system that tends to forget its timely working conditions in an exponential way (J.J. SLOTINE, 2002, p. 19)

SLOTINE writes: "If such a system is submitted to a temporary **perturbation** it will go back to what it was just doing- at that given moment" He adds: "...at least for small perturbations, such **robustness** is in fact a necessary condition for any **learning**: a system whose **responses** would be fundamentally different at each trial would be incomprehensible" (Ibid)

Moreover: "...the contraction property is automatically maintained by any combination (**parallel**, **serial** or **hierarchical**; and some types of **feedbacks**) or dynamical recombination of **subsystems**, when these are also contractant" (Ibid)

Generally, contraction is a **stabilization**, or even **self-stabilization** device in **nonlinear** systems.

→ **Le Chatelier (Principle of); Least action (Principle of); Regulation; Slaving Principle**

0678

CONTROL^{1) - 2)}**1 the concept**

D. Mc NEIL considers control as "... the re-ordering of **activity** with reference to ends". In the **toroidal paradigm** he proposes, "manifestations of control can be identified with the orientation and strength of a **toroidal** center, taken as a **channel**, a stem, a conduit, or even a gyroscopic axis complementary to a **looping flow of content**" (1993, p.11).

Aside from this very general view, we need a better **understanding** of the ways controls work, as related to **organization**, **stability** and **goals** or **purposes**.

J.Z. YOUNG writes that control is: "The **regulation** of the **operation** of a system by a **program** of instructions, often using **sensors** to detect **deviations** from a **reference** standard and initiate corrections" (1978, p.291).

St. KATZ writes: "In essence, control simply means the **regulation** of **magnitude**. Now to say that something is regulated implies that it may assume any of a number of values, i.e. it may vary or is variant. Yet, the very fact that we refer to it as "it" or "something" implies that the something being regulated has also a

permanent aspect about it, i.e., has a characteristic that remains constant or is **invariant**" (1976, p.43).

According to E. JANTSCH, control "is geared to **stability** and to the **optimization** of specific **parameters** under a **set** of fixed **constraints**" (1975, p.283).

All systems have controls, generally many ones, since they include a number of **processes** and **functions** that must be maintained within specific maxima and minima.

However, control is closely related to **variance** in the **environment**, which is generally the cause or the **trigger** of internal **variance** of the controlled system.

As any control is basically a **constraint**, the concept of control implies an **algorithm** relative to the necessarily predefined **limits**. However, such an **algorithm** may be implicit, as for example in the natural and reciprocal control of animal and/or vegetal **populations**.

In **machines**, control is normally ensured by some preconceived **mechanism**.

As a **constraint** (in ASHBY's terminology) any control prohibits certain **states** and **transformations** and allows others, under specific conditions.

Control also implies **hierarchy**, since the controlled **process** or **function** is submitted by some **command** device to limitations, that it cannot normally modify.

In many cases **hierarchic** control is **multi-level**: subsidiary or local controls are, in turn, commanded by more global ones. In H. PATTEE's words, **hierarchic** control aims at the: "**Optimization** of the **level** of **constraints** in forming new structural **levels** and in the **optimization** of loss of detail in forming new descriptive **levels**" (1973, as quoted by E. JANTSCH, 1975).

However, the concept of control is in some cases ambiguous or misinterpreted.

W.T. POWERS states: "A is said to control B if, for every disturbing influence acting on B, A generates an **action** that tends strongly to counteract the effect of the disturbing influence on B".

He adds: "It is important to understand from the start that this definition doesn't fit many of the common usages of the term. For example it is said in chemistry that temperature controls the rate of a chemical reaction. But that doesn't fit the definition: if some independent influence tends to change the **rate** of the reaction (stirring the mixture for example), the temperature will *not* change so as to counteract the effects of the **disturbance** on the reaction rate" (1995)

Control, as meant by POWERS, always implies the existence of a willful **controller** or a **goal-seeking** device purposely introduced.

0679

CONTROL^{1) - 2)}**2, the mechanism**⁵⁾

So-called "devices" are proper to man-made systems. Even so, some are abstract as, for example, controls on money supply by interest rates or the highway **code** which aims at regulating drivers habits by way of **norms**. On the contrary, no material **mechanisms** are conspicuous in natural systems like

populations, or biotopes: here the control is diffuse and statistical in character (see **Markovian process**).

Living systems have biological control devices, which regulate, for example, blood pressure, glycogen rate or perspiration. But these devices performance is automatic and non-volitive.

In any case, as stated by V.G. DROZIN, it is impossible to "... effectively control a **complex system** by using only promoters or suppressors" (1975, p.11).

0680

CONTROL (Alert)⁴⁾

According to E. HERRSCHER, "there are two **modes** of control in **organizations**: the **programmed control** and the alert control"(pers. comm., 2003)

He adds: "the alert control has no **routine**, no formal **procedures** established a priori, **no program**. Instead, it consists of an attitude of "being prepared for surprises" of having our antennas ready to react to any unforeseen **signal** that may be relevant for the organization's present or future **performance** or even **survival**"(Ibid)

Herrscher states that alert control has its original root in hearing and observes that "our ears cannot be closed (there are no "ear lids") and that in this way we are always able to perceive **emergencies**, as "sound reaches our senses whether we like it or not"(Ibid).

On the contrary, programmed control is not automatic and depends on our will and our **goals**, within the **limits** of our **frames of references**.

→ **Perception; Perceptual fields**

0681

CONTROL: basic elements.(its five)²⁾

According to O. JOHANSEN BERTOGLIO (1985, p.184-85) a control system includes five basic parts:

a) a **variable**: this is the **element** (or programmed **goal**) that must be controlled. Let us say a car's velocity

b) **sensors**: or **mechanisms** or devices able to perceive the **variable's fluctuations**. In the car's velocity case, we need a velocimeter, our visual capacity and our **brain's** interpretative capacity

c) **motors**: or **effectors**, able to develop corrective **action**. In this case, they include neurons, nerves and our muscular system to move our foot to accelerate or brake

d) an **energy source**: needed for any kind of **activity**. We need our stored physical **energy** and also, the **energy** that moves the **motor**

e) **feedbacks**: which, by **communication** of the **variable's state** registered by the **sensors**, **trigger** the corrective **action**. In this case they are the **decisions** made by our **brain**.

0682

CONTROL BY ERROR ^{2) - 5)}

Referring himself to the practical difficulties to achieve control by error, at least in some cases, W.R. ASHBY observed: "... the designer engineer may sometimes forget that there is another way to **regulation**. May I suggest that he would do well to bear in mind what has been found so advantageous in the biological world, and to consider whether a **regulation**, which is excessively difficult to design if it is controlled by error, may not be easier to design if controlled not by the error but by what gives rise to the error" (1958, p.93).

ASHBY observed that living **organisms** developed **channels** of **communication** with their **environment** to obtain "... **information** about **disturbances** before the chain of **cause** and **effect** goes so far as to cause actual error" (Ibid).

0683

CONTROL BY RECURSION ²⁾

A control organized at successive **meta-levels**.

This type of control is proper to **hierarchical systems**. J.P.van GIGCH explains: "In each control system, control exercised by the **controller** (CR) is called control at the **object level**,

From J. P. van GIGCH: 1986, p. 90

whereas control exercised by the metacontroller (MCR) is called control at the **metalevel** or **metacontrol**. The same denomination applies to subsequent **levels of recursion**" (1986, p.90).

→ "**Recursion (levels of)**"

0684

CONTROL (Chaotic) ¹⁾²⁾

A way to control a **chaotic system** by short bursts of intervention in its **behavior** at calculated moments.

This technique has been established on a mathematical basis by E. OTT et al. (1990).

It has been successfully applied to artificial satellites orbits in order to reduce fuel consumption when orbital corrections are needed. However, very complex **chaotic systems**, as for ex. atmospheric **perturbations**, cannot yet be controlled in this way, due to the considerable number of interacting **elements**.

0685

CONTROL (Forms of) ²⁾

Control can be introduced in numerous different ways. The following are indicated by L.E. BAYLISS (1966 - retranslated from the spanish translation - original unavailable):

- **auto-adaptive**: Return of a system's **function** toward its most adequate value by automatic **change** of the **parameters** (1968, p. 118).
- **integral**: Control operated upon a deviation, that becomes mathematically integrated in **time** (p.42)
- **nonlinear**: Intermittent control according to the existence of **thresholds** and saturation points in the **process** (p.42). (This is the on-off control).
- **proportional**: Control operated by a **regulating** device that produces at one moment a **signal** proportional to the deviation (p.38).
- **variable**: Control operated by a **regulating** device on the base of **memory** of former deviations (p.42).

Volitive controls could be added, being those that man establishes in artificial or natural systems that he wants to modify to his advantage.

0686

CONTROL (Hierarchic) ¹⁾²⁾

The control at each level by a higher **level** control.

P. CORNING writes: "...the principles that control higher **levels** may serve to restrict, **order** and "harness" lower levels". He uses an example by POLANYI (1968): "The grammatical **rules** that govern the **structure** of various human **languages** utilize but also subsume the principles of phonetics".

Thus, without **phonemes** there is no language.

But phonemes without some superseeding ordering cannot become a language.

This is another example of SABELLI's "**priority of the simple**" and "**supremacy of the complex**" (1994).

It also corresponds neatly with van GIGCH's **model** of control by **recursion** (1986). At higher levels, it becomes obvious that the relationship between the complex and the **elements** is bi-directional. A "revolt" of the elements- at time due to abuse of the higher complex can destroy the **whole**. For example, an alcoholic can destroy his liver...and as a result the liver destroys the alcoholic.

In P. CORNING's words: "...In short, there is **both upward and downward causation** in nature, and very often a **synthesis** of the two" (1998b, p. 14)

0687

CONTROL (Intrinsic) ^{2) - 4)}

"**Self-regulation** as distinguished from mere **regulation**" (St. BEER, 1968, p.262).

C. FRANÇOIS observes that we should find out how the system is naturally regulated before trying to control it... and this leads us to quite a tricky problem: we must evaluate how our controls would eventually impinge on the natural **regulators** (1978, p.4).

BEER observes that natural systems have "implicit controls" (p. 299) and **error** controlled **negative feedback**: "**equilibrium** is restored in the act to be lost" (p.353).

This is also the reason why in so many cases, authoritarian plans do not work in the long run and why human control frequently plays havoc with many natural systems, as for example with endemic malaria, agricultural pests, or so called "developing" countries economics and **social systems**.

0688

CONTROL MECHANISM ^{2) - 4)}

Any device that introduces **constraints** in the workings of a system.

The first step towards a control mechanism is given when two or more **elements** are becoming interactive in some definite way.

K. BOULDING gives the following detailed **description** of the control mechanism:

"A control mechanism always involves a number of **parts**. There must be: first a **receptor** of **information** (1) which picks up **information** regarding the **variable** to be controlled and, in particular, picks up **information** regarding **divergence** between the actual value of the **variable** and the **limits** of **tolerance**. In the simplest **mechanism**, all that is necessary is qualitative **information** about the sign of this **divergence**: the minimum **information** is that the **variable** is above the upper **limit** or below the lower **limit** of **tolerance**.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

"This **information** must be transmitted by a **communication system** (2)... to an executive or **decision maker** (3). The **function** of the executive is to transform the **information** received into instructions; it (or he) can be thought of as a kind of production **function**, receiving **information** by one **communications system** and sending out instructions over another (4).

"The instructions go to **effectors** (5) which carry out the instructions, and can produce an **effect**... "which is carried by another **communication system** (6) to the controlled **variable**" (1952, p.37).

At least two **elements** should be added to this description:

1 – In order to meet, or at least to register any divergence the **receptor** must be at the same time a **comparator**, or be connected with one. The **comparator** must compare the registered **input** with a previously incorporated **standard** and, possibly, with a register of former **states**. Only thus is any **information** created.

2 – Any **effector** needs the disposal of some spare **resources** to be used in order to be able to produce any **effect**. It should be for example a store of available **reserves** or a **source** of **energy**.

K. BOULDING gives the following example of control mechanism:

"Thus in the thermostatically controlled furnace, we have the thermostat (1) which registers **divergence** of the temperature from the tolerated **limits** (the upper and lower **limits** may in this case be contiguous). This **information** is transmitted by a wire (2) to the furnace control (3), which transforms the **information** into instructions sent by another wire(4) to the furnace (5), which is capable of transmitting the **effect** (heat) by a system of pipes and radiators (6) to the **environment** of the thermostat".

Thereafter BOULDING comments:

"The theory of the control mechanism has been developed in some detail by WIENER, and we need only mention some conclusions here. One is that a control mechanism always involves a **cyclical** movement of the controlled **variable**, the **amplitude** of the **cycle** being a **function** of the **sensitivity** of the mechanism. If the mechanism has pronounced **lags**, the corrective **effect** may only be brought into play after an extensive **divergence** of the controlled **variable** from the **norm** (or even after a spontaneous reversal of the **divergence**), and the correction may go too far before the counter-correction comes into play" (Ibid).

0689

CONTROL MECHANISMS (Problems in) ^{2) - 4)}

K. BOULDING states (1952) "In **organisations** of any degree of **complexity** there is not a single **variable** to be controlled but a large num-

ber of **variables**, and the **effectors** which affect one may also affect others. If each **variable** to be controlled has an isolated **effector** which is capable of controlling it, the multiplicity of **variables** presents no problem. We do not in general find this to be the case, however. **Action** which is taken to influence one **variable** will almost always have some effect on the others. If the **effectors** are sufficiently confused, the problem of control will become insoluble: in endeavoring to stabilize one **variable**, we inevitably unstabilize others; acute **cycles** may be set up and the **organization** may even desintegrate" (1952, p.389).

These effects appear clearly in the **systems dynamics models** created later on by J. FORRESTER. **Interactions** between **effectors**, **simultaneity** of effects in different **parts** of the **complex system** and **time lags (delays)** are very difficult to modelize satisfactorily... and to control.

As a result, in L. DOUGLAS KIEL words: "The traditional "engineering" view of public policy interventions intended to produce desired outcomes appear to better represent an abstract Newtonian vision, rather than the **uncertainty** of actual experience with such efforts. In short, the dynamic and **nonlinear** relationship between many **variables** in **social systems** reveals that policy decisions result in an enormity of unexpected outcomes" (1992, p.38).

0690

CONTROL (Multi-determined) ^{2) - 4)}

Most **behaviors** in natural **complex systems** are multi-determined, i.e. not controlled by only one device.

G. BATESON states: "Characteristically, every feature of the anatomy of an animal or plant and every detail of **behavior** is determined by a multitude of interacting factors at both the genetic and physiological **levels**; and, correspondingly, the **processes** of any ongoing **eco-system** are the outcome of multiple determination. Moreover, it is rather unusual to find that any feature of a biological system is at all directly determined by the need which it fulfils" (1973, p.476).

BATESON understands also that: "What is true of the species living together in a wood is also true of the groupings and sorts of people in a society, who are similarly in an uneasy balance of **dependency** and **competition**" (p.407).

Human engineering and **planning**, unfortunately, are much less sophisticated, not taking account of what lies directly in the path of their **purpose**. As a result, single-minded determination introduced in **processes** and controls frequently impairs **flexibility**, and even **survival** of the managed systems. Would be **controllers** should at least try to act prudently on **variables** that could prove "lethal".

Multi-determined control should seek to copy nature, where checks and counter-checks **interactions** tend to lead to better global **stability**.

0691

CONTROL (Negative) ^{2) - 4)}

"A **means** whereby courses are changed as to escape threats" (G. VICKERS, 1957, p.4).

VICKERS states: "Negative control reminds us that every system works within **limits** which cannot be passed without disaster. Some conditions must be preserved if the assembly is to hold together."

"... Thus all positive **goal seeking**, with the positive control which it involves, takes place within the **framework** of negative control, which ensures the continuance of the system" (p.4).

"... The control is designed to sense when the assembly is approaching the danger point; before this is reached, it remains inactive" (p.6).

Undoubtly, many contemporary problems in demographic, ecological and economic systems are a result of the general and obstinate ignorance of this **concept** of countervailing controls (enounced in 1957!).

0692

CONTROL OF and CONTROL FOR ^{1) - 2) - 4)}

Control, as a natural **process**, is non-volitive: it is basically the automatic result of reciprocal **constraints** between **elements**, **parts** or **whole** systems. It is obvious, for example, in **co-evolution**.

In contrast, human controls are mainly purposeful: the idea is to maintain a system within some specific **parameters**, or to the contrary, to enforce some new **parameters**, unfortunately sometimes arbitrary or even downright unsustainable, in order to change the system's **behavior** in a way desired by the **operator** and supposedly advantageous.

When inside and outside **contexts** (alike) are not duly taken into account, the results of volitive and purposeful control can easily be erratic, negative or even wholly disastrous (Ch. FRANÇOIS, 1983).

R. ESPEJO states: "... control is not a unilateral enforcement of **criteria** of **performance**, but rather the maintenance of a **dynamic stability** in the **interactions** among multiple viewpoints with reference to tacitly accepted, more or less flexible, **criteria** of **performance**" (1988, p.143).

A. RAPOPORT made the following somewhat controversial but quite significative comment: "... control of portions of the world become desirable not only for the **purpose** of exploiting the **environment** but also for the **purpose** of understanding it" (1972, p.18).

0693

CONTROL OR CONSTRAINT^{2) - 3)}

There is a subtle difference between both **concepts**. F. HEYLIGHEN writes: "... control is certainly a form of constraint. The basic difference seems to me that **control** requires a **controller**, that is to say a system separate from the system being controlled. In the **concept** of constraint it is not necessary (though it is possible) to situate the constraint in a separate system, the "constrainer". A constraint may be inherent in the system being constrained: the system may simply be the result of natural **selection**" (pers. comm.).

At least in **living systems** and in social ones, the system starts with its constraints, which give it its basic **autopoietic** characteristics.

As to control, HEYLIGHEN continues: "With control on the other hand, that control resides in a separate system, implies that there must be **channels of interaction** between **controller** and controlled. These **channels** will not be perfect. That means that **information** will not be transmitted completely or instantaneously. That implies that a variation of the controlled system cannot be exactly constrained: there will always be a **delay** between the start of the variation and the **reaction** of the **controller** constraining that variation. (Ibid).

In synthesis, control is by necessity somewhat imprecise and submitted to **time lags**. This means that any (human) **controller** should better be cautious and somewhat skeptical about the hoped for results.

0694

CONTROL (Positive)^{1) - 2) - 4)}

"A means whereby courses are chosen and kept so as to reach **goals**" (G. VICKERS, 1957, p.4).

Apart from the opposite **effects** of positive and negative controls, it should be noted that only humans seem able to choose positive control to reach their **goals**, at least at **macro- or megalevels of actions**.

Moreover they do not generally seem to be aware of the **accumulation** and potentially dangerous **effects** of repetitive **positive feedbacks**, used for positive control. This could very well lead to grave disasters now that mankind disposes of such powerful technical means.

0695

CONTROL (Programmed)⁴⁾

According to E. HERRSCHER, "there are two **modes of control in organization**: the programmed control and the **alert control**" (pers. comm., 2003)

He adds: "the programmed control consists of all the measurements, comparisons, indicators, audits, **observations**, reports and the like that have been established in order to assure an organization keeps on track and meets its **goals** as much as possible" (Ibid)

According to Herrscher, programmed control has its roots in seeing, a pre-active sense that responds "to our desire as to where to look, when to open and when to close (our eyes)" endowing us moreover with the capacity to focus our attention on specific **aims**.

On the contrary, the alert control is basically automatic, non specifically focused and always ready to react to **signals** of some imminent **emergency**.

→ **Perception; Perceptual field**

0696

CONTROL SPACE²⁾

The **set** of internal and external **parameters** of a system that are fixed by the experimenter (after R. THOM, 1993, p.39).

This set generates a global **configuration**, generally complex, i.e. divided into **regions** where one or another **attractor** dominates (Ibid).

0697

CONTROL (Symbolic)^{2) - 4)}

The collective maintenance of standard values of **meanings** in a culture.

Symbolic control is necessary to allow for the transgenerational transfer of **meanings** and general **knowledge**. It is obtained through **syntactic, semiotic and semantic rules**, generated through **conversation** among the participants of the culture and becomes stabilized by **autopoietic closure**. All kinds of schools, academies, etc..., as **transmitters** of all kinds of standardized **languages** are the most common symbolic controllers.

The idea was already clearly enounced by CONFUCIUS, when he insisted on the necessity of "correct designations" to maintain the "celestial order" in the chinese realms. He thus established the future cornerstone of imperial mandarinism, a typical symbolic control system.

0698

CONTROL SYSTEM (Characteristics of a)²⁾

According to O. JOHANSEN BERTOGLIO (1985, p.144-45) any control system needs the following characteristics:

- a **negative feedback**
- a **fixed point** of reference within a limited **vicinity**, wherein the **variable** must be kept
- a **repertory of states** which allows it to give an efficient **response** to any normal and specific **stimulus**

This last point is thus stated by G. PASK: "The amount of control (measured as a **variety**) depends upon the amount of **information** the **controller** gleans from the **environment**" (1961, p.53). This is equivalent to ASHBY's **Law of requisite variety**.

0699

CONTROL SYSTEM (in living systems)¹⁾²⁾⁵⁾

W. POWERS states: "Living **organisms** don't produce repeatable **actions**. They produce repeatable results" (1995, p.3)

He adds: "The theory of **control systems**, ... shows us how a relatively simple system can manage to produce reliable and repeatable results in an **environment** that has a large **component of unpredictability** - in other words, in the real world".

And "If you start with the idea that a behaving system controls outcomes or results rather than the actions that produce them, you can invent **control** theory from scratch. The first thing you realize is that this can't be done just by creating reproducible **actions**. The same action will have different results depending on what is going on in the environment. What you want is some basically simple way to produce a given result that doesn't depend on being able to predict exactly what action will be needed to produce it" (Ibid).

This is a very important comment, as it brings us back to the bedrock of **cybernetics**.

It also leads directly to HOLLAND's genetic adaptive plan through **rules** and to "**artificial life**" devices.

Finally, it is equivalent to VENDRYES' concept of **living systems**, able to control their own **relationship** with their environment, i.e. **autonomy**

0700

CONTROL (Time factor in)²⁾

G. VICKERS states: "Clearly problems of control are haunted by a complicated **time** factor. Each **signal** presents information derived from the past and initiates **action** which will take effect in the future. The effect of the **action**, more or less masked by other **variables**, will return for judgment at a still more remote point of **time**. Thus control is possible, even theoretically, only within **limits**; and these may present themselves as **thresholds** which are passed suddenly...

"The **span** between taking a **decision** and the comparison of its actual with its intended results ranges from seconds to years; and the longer it is, the more likely it becomes that no comparison will ever be possible, since so many **variables** will have contributed to affect the result" (1957, p.5).

This problem is closely related to **chaotic determinism**, in **complex systems**, prone to divergent **bifurcations**, whose theory was not yet developed when VICKERS wrote these lines (showing his impressive vision).

While his comment relates to volitive controls, it is no less evident that **long term** effects of natural controls are as difficult to predict... or more difficult still, because many of them are so ill understood.

0701

CONTROL (Time-Lag in) ²⁾

According to G. BATESON, in **homeostatic** systems: "... it is important that the highest system of control *lag behind* the **event** sequences in the peripheral **homeostatic circuit**" (1973, p.325).

This somewhat counter-intuitive view (also apparently contradictory to VICKERS' views), reflects the necessary **hierarchies** in **complex systems** controls. Basic **long-term regulations** must necessarily supersede **short-term fluctuations** of lesser **periods** and **amplitudes**, if they are to remain coherent and to keep in working order the general **organization** of the system.

0702

CONTROLLER ²⁾

"A natural or constructed assembly which interacts with its **environment** to bring about a particular **stability** called the "**goal**" or "**objective**" (G. PASK, 1960, p.49).

G. PASK explains: "Indeed, whenever there is a **stable system**, then, in principle, we can envisage a **subsystem** acting as the controller that maintains this **stability**" (Ibid).

Constructed controllers are generally based on quite simple **feedbacks**, but in natural systems a controller is frequently composed of a complex of countervailing **feedbacks**. In **Marxovian systems** or in **composite systems**, no specific controller can be found: the **control function**, as well as the "**goal**" or "**objective**", is diffuse in the whole system and is a result of statistical **interactions** among the **elements**, within however global limiting conditions.

As to human controllers (or would-be controllers), they should never forget Sir Francis BACON warning: "Nature, to be commanded, must be obeyed".

This implies a correct **understanding** of natural **feedbacks** and **regulations**, previously to any intervention.

0703

CONTROLLER (Adaptive) ^{1) - 2) - 4)}

A control device "which adapt the **decision rule** in order to achieve **stability** in a given **environment**" (G. PASK, 1961, p.61).

PASK contemplates two applications:

"In one the **environment** is unknown but **stationary**, when the adaptive controller is used to perform experiments which *could* have been done by its designer, to build a **model** and to determine an optimum **decision rule**. In the other, the **environment** is non-**stationary** and the controller *must* continually relearn about it" (Ibid).

In this last case the controller must become **hierarchically** organized. In order not to be overwhelmed by the **environment's** multiple and unpredictable variations, a **selector of inputs** equipped with a suitable **memory** must be incorporated in the global **control** system. As noted by PASK, this is the role played by a good secretary for a manager.

0704

CONTROLLER (Automatic) ²⁾

G. PASK states: "Automatic controllers receive perfect **information** about the system they control and have fixed **decision rules**, that determine their action" (1960, p.53).

This is satisfactory if and when there is no need for the system to modify too much its **behavior**. However, strong **environmental perturbations** may very well put the automatic controller out of use.

To quote PASK again: "The automatic controller is inert... It cannot prod its **environment**" (p.54).

0705

CONTROLLER (Imitative) ²⁾

G. PASK thus explains the imitative controller: "It comes into its own when *no signal*... is available although the **knowledge** of results **data** is intact... Since the controller has no direct evidence of the **state** of its **environment**, is cannot "learn to recognize" like the predictive devices. Instead the **machine** "prods" its **environment** by an **autonomous trial** making **behavior**. Then it learns which forms of **behavior** lead to the best results... the **machine learns to imitate**" (1961, p.59).

PASK signals that the term 'imitative' is due to D. Mac KAY (1956).

0706

CONTROLLER (Overall) ²⁾

A controller that makes trial **adjustments** and chooses whichever of these gives the greatest positive increment of a defined **reward variable**. (Adapted from G. PASK, 1962, p.65).

"Overall controllers of this kind are often called "hill climbers" or **optimizers**" (Ibid).

However, in a complex setting, wherein different unequal **optima** are separated by suboptimal **zones**, an **iterative refinement algorithm** may be needed in order to reach the true **optimum**.

0707

CONTROLLER (Predictive) ²⁾

A controller that can learn to recognize some **states** of the system or the **environment**.

The predictive controller can at least "blow the whistle" and, in some cases, take anticipative measures to maintain the **stability** of the system. Therefore, it must be endowed with specific **decision rules**, preadapted to a **variety** of possibilities.

→ **Behavior (Anticipatory)**

0708

CONTROLLERS (Hierarchies of) ^{1) - 2)}

G. PASK describes such a hierarchy as follows: "The lowest **level** controller imitates its **environment**, learning that *a* is more likely than *b*. The second **level** learns sequences, *a* then *b*, or *b* then *a*. The next **level** learns about and imitates *sequences as a whole*, not *a* or *b* as such, and further **levels** learn about *categories of sequences*. In other words, "sequences" and "categories of sequences" become represented by **symbols** at different **levels** of discourse and the **artifact** performs a **non-trivial abstraction**" (1962, p.66).

From the viewpoint of the nature of **abstraction**, this should be compared with KORZYBSKI's **structural differential**. (1950).

From the viewpoint of biological or human **organization**, it helps understand how a differential power to generalize leads unavoidably to the shaping of **hierarchies**.

According to St. KATZ: "The **hierarchical** arrangement as a whole is designed to carry out the highest **order goals** of the **organism**; lower **order goals** are simply **means** to this highest end" (1976, p.45).

0709

CONVERGENCE ^{1) - 2) - 4)}

The move toward a predefined result or **goal**.

Seeking convergence is very important in the **management of concrete systems** and specially in **planning** activities with a great number of intermediate stages, as for instance investment programs, construction of industrial complexes, **development** programs of any kind, research programs, etc... As shown by St. BEER, the successive **interactions** between the **elements** and/or **subsystems** can generally be modeled by a **flow graph** representing the "ramified system" (1966, Ch.9).

Convergence can be spontaneous, or not, as **complex systems** easily show **chaotic behavior**. A **graph network** flowing through the **time** dimension can be made less stochastic, but then only under the condition of the presence

of an efficient **control** tending to diminish **indeterminacy** through the introduction of **feedbacked information**.

Failures to do so may become quite costly. BEER gives the following example: "It could thus happen, by a concatenation of... circumstances, that a two weeks delay encountered within the construction **program** itself might result (let us say) in a six-month postponement of the final completion. This outcome would be thanks to the ramification of the system concerned: it begins to act as an *amplifier of delays*" (p.192).

E. LASZLO equates convergence with the formation of **catalytic hypercycles**: "The outcome of convergence is a higher-level system that selectively disregards many details of the **dynamics** of its **subsystems** and imposes an internal **constraint** that forces the **subsystems** into a collective **mode** of functioning" (1987, p.34).

K. KRIPPENDORFF indicates the following social meaning for convergence: "The convergence **model** of **communication** postulates that as people communicate with each other they become more similar in **knowledge** and in attitudes and thus converge to form a **homogeneous distribution**" (1986, p.18). It should possibly be better to merely speak of a "*more homogeneous distribution*". Moreover, convergence can be obtained only through a well organized **conversation**.

0710

CONVERGENCE AND DIVERGENCE IN THE BRAIN²⁾⁵⁾

J. ECCLES sums up these two basic features in **neuron networks**, as follows

"*Principle of convergence*: the feature of the **nervous system** in which many nerve **cells** project to a single **neuron**

"*Principle of divergence*: the feature of the nervous system in which one neuron branches to be distributed widely to other neurons"(1977, p. 241)

The **complementary** of convergence and divergence transforms the neuron network into a gigantic **graph** potentially and conditionally connected in a practically infinite number of ways.

Both principles taken together are obviously a general condition for any network, i.e. for any social **communication net**. It is suggestive that:

- either we model our social exchanges in accordance with our **neural organization**
- or that our neural organization clearly allows us to create mental means conducive to **sociality**

0711

CONVERSATION^{1) - 4)}

Interaction between two or more participants.

This concept has been introduced by G. PASK, who states: "A conversation takes place within a contractual **framework**; and *this* rather than a **stimulus/response** system, is argued to be the *least* meaningful experimental **situation**. In a conversation it is possible to observe *psychological events*; in other **situations** it is *not*. **Observation** consists in recording and interpreting **dialogue** between the participant individuals. Experimental **regulation**, **parameter change**, etc., is achieved by instructing one *participant* to execute a prescribed **heuristic**. It is crucial however, that the participant does so, and not the **observer** and that he retains the partiality as well as the liberty of a participant. Hence the **heuristic** is not to be equated with an **algorithm**" (1972, p.3).

G. McINTYRE BOYD states: "PASK's p-individuals can interact at five **levels**:

1. - the **level** of direct **action** in a shared **space**
2. - the **level** of simply naming each **action** taken (in the **protolanguage L**)
3. - the level of conveying explanations of these **actions**
4. - the **level** of explanations of the explanations - the top **level** of "teachback" (also in L)
5. - the **level** of negotiation of the engagement to converse and specification of the scope of discourse and other **rules** (This is the **level** of the **metalanguage L**") (1993, p.121).

By its very nature conversation is thus circular, or better, cyclical, as observed by R. GLANVILLE (1993, p.52).

Conversation generally leads to **consensus** and the common acceptance of some "**truth**", but this may sometimes happen after protracted debate and even **conflict**.

As stated by F. ROBB: "... agreed **meanings** are formed by negotiation or compulsion... The formation of **meanings**, in this **context**, is taken to include making **distinctions** between **objects** in experience (or in thought) and their ground, forming mental **models** and making valuations about **situations** and **objects**; so that 'good' is discriminated from 'bad', 'desirable' from 'undesirable', and 'true' from 'false'... Conversations may also negotiate what constitute valid ways of making these **distinctions** and of establishing these **values**" (1993, p.1).

Finally, in D. GREGORY's words: "Conversation theory is nothing more - and nothing less - than the attempt to model the way in which we manipulate our **metaphorical** systems to construct shared **meaning** and thereby, come to agree with one another over what we understand" (1993, p.71).

Thus, as stated by R. GLANVILLE: "Conversation is not a linguistic device: **language** is a conversational device"(2001, p. 147)

However, behind the **mechanisms** and the **cybernetics** of conversation, there is a psychological aspect, thus described by K. BAUSCH: (Conversation implies) "listening without judging, without a predetermined personal agenda, and with a willingness to suspend one's own **assumptions**. True dialogue is thinking together, in BÖHM's words, so that new **meaning** may emerge. conversation is the main vehicle for collaborative **learning** and in **design processes**, it is the process that makes images of the future shared and public"(pers. comm.)

The relations with **constructivism** and with mental **autopoiesis** are obvious.

0712

CONVERSATIONAL DOMAIN¹⁾

The **set** of topics debated by participants in a **conversation**.

This **concept** has been introduced by G. PASK, according to whom the "... individuals... participate in a **process** of **understanding**, retaining and **learning** that goes on" (1972, p.3).

Eventually, **consensus** may be reached or reformed about the **meanings** within the conversational domain, or some shift toward another domain may take place.

0713

CONVERSATION (Reflective)

→ **Stigmergy**

0714

CONVERTER^{1) - 2)}

"The **subsystem** which changes certain **inputs** to the system into forms more useful for the special **process** of that particular system" (J.G. MILLER, 1978, p.3).

The converter is one of MILLER's **20 critical subsystems**. It transforms **matter** and **energy inputs**. Any **complex system** may have many different specialized converters.

0715

COOPERATION¹⁾

N. TINBERGEN wrote already in 1965 in his "Social Behavior in Animals" that the result of cooperation of individuals is continually tested and checked and thus the group determines ultimately, through its **efficiency**, the properties of the individual.

It is now well understood that cooperation is a special aspect of **interaction** within **networks** in a specific **environment**. Each individual or **element** is communicating with a number of other ones within the group or the species or, in case of men, the **organizations** in which it participates.

In many cases, but not all, it is also directly related to some specific part of the **environment** and serves as a **transmitter** of the **environment** reactions to its **activity** and, in some

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

cases, to the activities of other members of the **group**. It (or she/he) may then, willingly or not, have to pay for some ill adjusted proper or groupal **behavior**.

0716

COOPERATION as an evolutive process^{1) - 2)}

F. HEYLIGHEN describes as follows the complete evolutionary sequence leading from **competition** to cooperation: "... **competition**, **communication**, stable **interaction patterns**, internal **models** of **patterns**, shared **models**, shared **replicators**, cooperation promoted by shared **replicators**, **integration** with the shared **replicators** as coordinators" (1992b, p.25)

This is clearly a **cybernetic model** which includes for example G. PASK's "**conversation**", with its reciprocal **accomodation process** (**consensus** – von FOERSTER **cybernetics of second order**), GABOR'S and Mac KAY'S "**log-on**", shaping of a **hierarchy** through the appearance of a **regulator**.

And, in E.von GLASERSFELD's words: "... the **situation** of reciprocal instrumentality has the potential of developing into collaboration" (1988, p.51).

0717

COOPERATIVE STRUCTURE^{1) - 2)}

Cooperative structures are observed in all social animals. They are also now researched within the frame of A.I. and are acquiring a very general **meaning**, as a **model** of **self-organization** of complex **wholes** by reciprocally regulating **interactions** between **elements** formerly independent from each others. This is basically a **bottom-up phenomenon**, governed by **generative rules**, closely related to **cellular automata**.

Construction of cooperative structures is also **recursive** and seems even to have been one of the most important factors in general **evolution**, as a stepping stone to ever higher **levels** of **sociality**, as shown by C. BRESCH (1977, 1987).

More recently, a number of researchers started to study more elaborated **models** of cooperative structures, mainly through the new discipline called **Artificial Life** (A.L.). For detailed information see, under others, C. LANGTON (Ed.), 1989 and the SIGART Collection on Integrated Cognitive Architecture (1991).

0718

CO-OPERATIVE SYSTEMS

→ **Systems (Cooperative)**

0719

COOPERATIVITY²⁾

According to V. ROWLAND, cooperativity is a typical property of **elements** in **networks**: "... the property of neurons interacting with their immediate neighbors and generating by this means, sudden **transitions** from noncooperative to cooperative **dynamics**" (1976, p.123).

ROWLAND traces cooperativity back to atomic, molecular and magnetic **phenomena**.

Cooperativity, in this sense, is probably the initial step toward **sociality**. It is related to **percolation** and the unstable **behavior** of **composite systems**.

0720

COORDINATION^{1) - 2) - 4)}

The **synergetic** functioning of the **subsystems** within a system.

General coordination depends on some **elements** being widely connected into the different **parts** of the system, in such a way as to be able among them to collect the most complete and recent **information** about the system as a **whole** and use it to avoid incompatibilities between **processes**.

This is the case for instance of some neurons whose axons diverge into the whole **brain** (J.P. CHANGEUX, 1992, p.710), or of the national political and administrative **subsystem** within a country.

Coordination tends to be, but is not necessarily automatic, specially in **human systems**.

M.D. MESAROVIC, D. MACKO and Y. TAKAHARA state: "To coordinate the **subsystems** is to influence them so that they function or act harmoniously, such as one would coordinate the **activities** of individuals or **groups** within an **organization**. To make this idea of coordination operational, one has to define more explicitly what is meant by "acting harmoniously". In general, "this is done in reference to a **goal** or **objective**, so that the **whole** achieves the stated **objective**".

"Coordination is the task of the supremal **control** system, in which it attempts to cause a harmonious functioning of the infimal **control** system.

"The success of the supremal in its task of coordination is judged relative to a given overall **goal** of the **two-level system**. Since the infimal **control systems** operate so as to achieve their own individual **goals**, a **conflict** generally develops among them and results in a prescribed overall **goal** most likely not being attained. The task of a coordinator is precisely aimed at reducing the consequences of such an intra-organizational **conflict**, if not to eliminate it altogether" (1970, p.93-4).

The same authors distinguish the following types of coordination:

- **interactive – predictive**: "The supremal unit specifies the **interface input**, and the infimal units proceed to solve their local **decision** problems on the assumption that the **interface input** will be exactly as predicted by the supremal unit"
 - **interactive – estimative**: "The supremal unit specifies a range of values for the **interface inputs**, and the infimal units treat the **interface inputs** as **disturbances** which can assume any value in the given **range**"
 - **interactive – decoupling**: "The infimal units treat the **interface input** as an additional **decision variable**; they solve their **decision** problems as if the **value** of the **interface input** could be chosen at will"
 - **load-type**: "The infimal units recognize the existence of other **decision** units on the same **level**; the supremal unit provides the infimal units with a **model** of the **relationship** between its **action** and the **response of the system**"
 - **coalition-type**: "The infimal units recognize the existence of other **decision** units on the same **level**; the supremal unit specifies what kind of **communications** are allowed between them. This leads to a coalition or competitive (**game theoretic type**) **relationship** between the infimal units" (1970, p.59-60).
- All in all these 1970 comments mostly reflect a quite traditional **top-down** authoritarian view of coordination. The **heterarchical** or **holographic** view of **organizations** which appeared more recently suggests that coordination is notably furthered by reciprocal **understanding** among **subsystems**.

Coordination is also obvious in natural systems – biological or ecological – and it is by no means evident that it is done in an exclusively **hierarchical** way.

0721

COORIENTATION^{1) - 2) - 4)}

The **behavior** of **elements** trying to harmonize their **interactions** or **relationships** in conformity with the global ordering of the system they are **part** of.

This implies the necessity to perceive – at least up to a point – this global ordering. Coorientation is thus an important aspect of **autopoietic catalytic cycles** (M. EIGEN). In animal **sociosystems**, the needed **perception** is biochemical (bees, ants) or visual (fish shoals) or auditive (cetaceans). In human systems, the main coorientation **mechanisms** are **values** and **norms**, shared mainly through spoken or bodily language.

Coorientation derives ultimately into a global **constraint**, or **order parameter**, that **synchronizes** the collective **behavior**.

0722

COPRODUCER²⁾

A **producer subsystem** that associates with one or more other **producer subsystems** to form some energetic, material or informative **association** needed by the system.

This is *not* one of J. MILLER's **20 critical subsystems**. Coproduction, however, is quite frequently observed in systems.

0723

CORE (Frozen)²⁾

"A connected mesh of **elements** that are effectively locked into either an active or inactive **state**" (1991, p.67)

According to St. KAUFFMAN, who introduces this **model**: "The frozen core creates interlinked walls of **constancy** that *percolate* or grow across the entire system. As a result, the system is partitioned into an unchanging frozen core and islands of changing **elements**. These islands are functionally isolated: **changes** in the activities of one island cannot propagate through the frozen core to other islands. The system as a whole becomes orderly because **changes** in its **behavior** must remain small and local. Low **connectivity** is therefore a sufficient condition for orderly **behavior** to arise in disordered **switching** systems".

Obviously, KAUFFMAN rediscovered ASHBY's **understanding** of the nature of **poorly or richly joined systems** and the importance of **constraints**.

Frozen cores may also explain the origin of **structures** and is reminiscent of LAVILLE's concept of permanent **whirls**, of D. Mc NEIL's **model** of **toroid**, and even possibly of d'ARCY THOMPSON's discoveries about the evolution of **forms**.

0724

CORPUSCULAR ADDITIVITY IN SYSTEMS²⁾

I.V. BLAUBERG, V.N. SADOVSKY and E.G. YUDIN observe (after A. MALINOWSKY) that, in **living systems** "In proceeding from the lower **levels**, bordering on molecular biology, to the higher ones (those of the **cell**, the **tissue**, the **organism**, the **species**, etc) a regular alternation of... two types of **organization** may be observed: paired chromosomes (corpuscular property), **complementarity** of the nucleus and the cell (rigid **relation**), **cells** of the same tissue (corpuscular property), mutual **complementarity** of tissues, multiple **organs** or their **parts** (corpuscular property), **relations** between systems of **organs** (rigid **relations**), individuals of the same sex (corpuscular properties), **complementarity** of sexes (rigid **relations**), etc." (1977, p.217).

0725

CORRELATION²⁾

"The **relation** between two series such as for every **part** of one series there is a corresponding **part** in the other series and no **part** of either series is without a corresponding **part** in the other".

J. FEIBLEMAN and J.W. FRIEND add to their definition that the correlation can be: "one-many; one-one; many-one, many-many" (1969, p.33). Any **relation** implies one or another of these types of correlation.

The existence of correlations constitutes the base for **homeomorphies** and **isomorphies**. For example, any **integrated system** possesses a **boundary** (its contact **subsystem** with its **environment**) and, in the above **meaning**, there is a **functional** and **structural** correlation between the **boundary** and some internal **subsystems** as well as with some **parts** of the **environment**. In the realm of **models**, **isomorphies** signal correlations between similar aspects of otherwise different systems.

Correlation is also understood as the permanence of **interrelations** within a system, a condition basic for its **stability**, i.e. a **co-variance** of some significant **processes**. S. DINER writes accordingly: "The reduction of correlation between more and more distant points on a **trajectory** is in fact the fundamental mark of the appearance of a **random** character. This is basically **deterministic chaos**" (1992, p.351). De-correlation implies thus a kind of **memory** loss of its **initial conditions** by the system.

There is a **critical distance** for correlation, which depends on the **field's parameters**. This implies that **interactions** become negligible beyond some specific **limit** – which does not necessarily means inexistant, if D. BOHM's **implicate order** idea is accepted.

Correlations frequently are significant **clues** for the study of systems.

Correlations can be causal, complementary, parallel or reciprocal. In such cases, they are generally obvious...but not necessarily very clearly and well understood. Neither are their **evolution** in **time** precisely established. **Growth phenomena** for instance can be of quite different kinds, reflecting diverse types of correlations.

A particular, but very interesting case is the **association** that can be created, or at least supposed or attempted, between two statistical series related to different **sequences of events**.

A certain **parallelism** or **similarity** between such series can be significant, but not necessarily so: the correlation between smoking and lungs cancer was widely and protractedly discussed before the **cause-effect** relation became well established and generally recognized.

In any case correlations between two **processes** can be a consequence of a common causal **link** with a third process.

The study of correlations is a quite developed part of statistical analysis and includes **frequency distribution**, **time** series analysis, **linear** and **non linear trends**, theory of sampling, **graphs**, **matrixes** and tables, coefficients of **reliability**, etc.

Correlation as a forecasting tool

Correlation in **time** with some seemingly or possibly related developments in technically connected fields is an important **forecasting** tool. For example, the use of micro-electronics in the construction of radio sets was a significant technical novelty whose impact on the radio sets industry could be more or less predicted by perceptive industrialists in the field... and ruin the business of the others.

I.G. BLOOR states: "The correlation technique attempts to put a value on the strength of any **relationship** producing a so-called "correlation coefficient" in the range of +1 to -1. The stronger correlation is +1." (1987, p.7). When practically possible, correlation calculation would be very useful.

0726

CORRELATION AND CAUSALITY¹⁾³⁾

A statistical correspondance between two or various series of **observations** related to the **behavior** of the same or various entities can be fortuitous.

Accordingly, correlation does not necessarily imply a causal **link**.

Such a **link** may be established only when:

- one **phenomenon** can normally be explained by the preceeding occurrence of the other
- both observed **phenomena** can be explained as different consequences of another one

Anyhow, correlations should in many cases be considered as an indication of a possible causal **relationship** and investigated as such.

0727

CORRELATION DEVICE^{1) - 2)}

As early as 1924, A. LOTKA observed that, what he was calling "natural mobile transformers", i.e. animals, could be **autokinetic** only as much as they were able to adjust their **behavior** to the variable circumstances of their **environment**. In order to do this, they need an internal device able to represent to themselves any variation of their relation with their **environment**. LOTKA introduced the term "**depictor**", to designate such a device and described it as follows: "The depictors include first the **Receptors** or Organs of Special Sense (eyes, ears, nose, etc...); and second the **Elaborators**, whose **function** is to combine and further elaborate the crude **information** furnished by the senses. The physical location and **structure** and mode of **operation** of the **elaborators**

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

is much less obvious than that of the **receptors**. In fact, we ordinarily recognize them rather as faculties (**Memory**, Reason) than as **organs**.

"Another set of **organs** and faculties, the **Adjustors**, determine the particular reactions, the **behavior** of the **organism**, in the light of the **information** brought in by the **receptors** and further elaborated by the **elaborators**...

"The last step, **action**, commonly involves the use of members, or **motor organs**, **effectors**, such as wings, feet, hands, etc... In complicated cases, as in human **behavior**, the **elaborators** may also play an important role in the **effector** step of the **process** by which motion is correlated to **environment**, **behavior** adapted to circumstances" (1956, p.340)

In this case, **prediction** and **planning** do appear and a unique and immediate **behavior** is replaced by a sequence of planned projected **behaviors**, oriented towards the future and with specified schedule. Such a device is obviously indispensable in any **artificial intelligent system**, endowed with **autonomous behavior**. LOTKA himself described such an **automaton** (a mechanical walking beetle).

The **analogy** of the correlation device with some of J.G. MILLER's critical **subsystems** is striking.

0728

CORRELATION DIMENSION ²⁾

"A number that measures the degree to which the system's **attractor** "fills up" the **space of states**" (J. CASTI, 1994, p.101).

CASTI states: "The correlation dimension weights the points on the **attractor** according to how frequently they are visited... A telltale **sign of chaos** is when the correlation dimension turns to have a noninteger value much greater than 1" (Ibid).

Thus, in such a case, fractionary correlation implies **deterministic randomness**.

See: **FEIGENBAUM's number**.

0729

CORRELATION (Directive) ²⁾

Permanent or at least recurrent **interrelation** entailing a reciprocal **control** between two or more **functions** in a system, such as their interconnected action converges toward some coherent **behavior**.

G. SOMMERHOFF defines this concept in a formalized way (1969, p.174-5) and proposes it as a suitable alternative to the so-called "**Goal-directness**", which has finalists overtones.

Directive correlations undergo **reinforcements** with **time**. They are the base of all types of **adaptation**, on **short**, **medium** or **long term** (p.177-81). They seem closely linked with the concepts of **self-regulation**, **autopoiesis**, **organizational closure** and **hypercycle**.

G. SOMMERHOFF emphasizes moreover that "Every directive correlation has a precise signification only in relation to the **historical** period of reference" (p.187). The most robust directive correlations are those which correspond to the oldest and most confirmed **adaptations**.

0730

CORRELATION LENGTH ²⁾

Maximal propagation distance of the effect of some **disturbance** within a **net** (after K. WILSON, 1989, p.92).

This maximal distance plays an important role in **composite systems**, as it commands the **percolation phenomena**.

WILSON observes that: "Regions separated by a distance superior to the correlation length are independent" (Ibid).

The correlation length is variable according to the **state** of the system. It is major in strongly connected systems and less so in weakly connected ones.

This is verified for example in the disappearance of magnetization at some distinct temperature (CURIE's temperature) (Ibid), or in the spontaneous extinction of a forest fire inside of the already burnt down zone or, again, in the extinction of a pandemy when the number of victims exceeds some defined **limit**.

WILSON points out that: "That which is most significant when the correlation length increases is that the small variations do not disappear when variations of a greater **size** expand: they merely become a finer **structure**, superposed to the larger scale **structure**" (Ibid).

As a result, systems of this type show a **fractal structure** and may manifest local **behaviors** at variance with the global one.

0731

CORRELATION (Potential directive) ^{1) - 2)}

Aptitude for reciprocal **control interactions**, which are activated only when certain **environmental variations** make it necessary.

This type of correlation appears for example when a hungry animal reaches a state of alertness and starts to run after a prey. G. SOMMERHOFF writes, moreover: "An animal in a state of alertness is not just in a state of potential **activity**, but of potential activity of a *certain kind*" (1969, p.192).

According to SOMMERHOFF the concept is no less important in order to explain search or impulsive **behavior**, or **social integration**. In this last case, he emphasizes the fact that social **cohesion** refers not only to what **components** are doing in general, but to what they should do if some specific situation should happen. He gives the following example: "A patriot is not a patriot so much by virtue of what he

does at every moment of his daily routine, but by virtue of what he would do in certain special contingencies, as in a case of a national emergency" (p.193).

0732

CORRELATION (Spurious) ¹⁾

According to some early critics of G.S.T., most **analogies** lead only to senseless comparisons between widely different entities (R.C. BUCK, 1956).

Of course, **analogy** is merely a *weak heuristic* tool... but is it better than none. Moreover, an **analogy** may lead to an **homology** or **isomorphism**, i.e. a more formalized **model** that can be applied to different **objects** of study.

BERTALANFFY writes: "Buck's criticism is, in principle, the same as if one would criticize NEWTON's law because it draws a loose "**analogy**" between apples, planets, ebb and tide and many other entities; or if one would declare the theory of probability meaningless because it is concerned with the "**analogy**" of games of dice, mortality statistics, molecules in a gas, the **distribution** of hereditary characteristics, and a host of other **phenomena**" (1962, p.9).

0733

CORRELATIONS (Complex) ²⁾

Interferences variable in **time** between multiple **elements** or **factors**.

This kind of correlations is frequent in **ecosystems**, specially in perturbed ones.

A **population** crash of some **parasitic** or predator species may transform definitively the general more or less **cyclical dynamics** of the system and permanently change the **relations** of **equilibrium** among its **components**, some of which could even disappear.

It seems possible that a factor like technological acceleration could produce this type of **transformation** between specialized groups in human societies, some of them being eliminated and others emerging or becoming dominant.

0734

CORRELATIONS (HIERARCHIES of directive) ²⁾

G. SOMMERHOFF introduced this concept in order to account for directive correlations of directive correlations.

He wrote: "Sometimes the **goal** of a directive correlation at one **level** of the **hierarchy** is a correlated **variable** in a directive correlation at the next higher **level**" (1969, p.189)

General correlations of this type allow the **integration** of the system as a specific **whole**, whose most general **goal** is its own **survival** as such.

Hierarchies of directive correlations do result of **learning processes**, but then only on the basis of potentialities acquired by the system at the moment of its **autogenesis**.

0735

CORRESPONDENCE PRINCIPLE³⁾

"Any new theory should reduce to the old theory for those cases in which the old theory is known to hold" (St. UMPLEBY, 1979, p.11).

UMPLEBY attributes the principle to H.von FOERSTER. He however adds: "This principle assumes that science grows somewhat like concentric circles" (Ibid).

This **phenomenon** is a quite general feature of science evolution during the 20th Century and finds its most general explanation in **GÖDEL's theorem**.

0736

COST^{1) - 2) - 4)}

"... the potential **energy flow** into heat necessary for a **process**" (1971, p.187).

This somewhat surprising but quite universal systemic generalization of the **concept** of cost by H. ODUM is in perfect accordance with the **2nd law of thermodynamics**, which controls all cosmic (and human) activities.

The practical lack of a systemic concept of cost is one of the most serious hidden problem of our time, since **long term** or indirect costs remain hidden due to ignorance or malicious concealment.

Even ODUM proposal should be extended, since any **process** is part of a system's **activity**, which in turn takes place in an **environment** whose correct and complete **description**, and **evaluation** is seldom considered.

An excellent example is the "cost" of oil, a non-renewable **resource**. Is it the cost of its discovery, extraction, transport and refining? Or should it include the **environmental** costs of its use? Or should it take in account the very difficulty to calculate costs of its replacement as a non-renewable **resource**?

For the concept of benefit per unit cost, see **Foraging theory**.

0737

COUNTER-INTUITIVE BEHAVIOR^{1) - 3)}

R. ROSEN states: "... in general the **behavior** of **complex systems** is "counter-intuitive": ... large systems generally act in quite a different manner than is expected from "common sense" considerations" (1974, p.94).

The same point has been made by J. FORRESTER in relation to his **Systems Dynamics**.

The main reason is given as follows by ROSEN: "Basically, it is because such intuitions we have about systems are drawn from systems which are in some sense "simple" (Ibid).

Complexity, as a result of numerous intertwined **interrelations**, is quite difficult to grasp entirely and unsound simplifications are normal, even in trained persons. **Deterministic chaos** theory has recently revealed a new and surprising dimension of unsuspected **behavior** of **complex systems**.

Ignorance of counter-intuitive behavior leads easily to inappropriate policies. Some initiative taken in order to alleviate a critical **process** in a system, while seemingly logical in an intuitive way, may actually turn the **situation** still more critical in the future. R. ARNOTT and K. SMALL give the following example: "Expanding road capacity creates its own demand, a phenomenon known as the Pigou-Knight-Downs Paradox... Expanding capacity *only attracts more users*" (1994, p.448).

This merely fuels a **positive feedback**, at least until basic **resources** are totally used up or sky-rocketing **costs** block the **positive feedback**.

0738

COUPLING (De-)²⁾

Mode of protection from **environmental disturbances** by way of an isolating device.

This is not a **regulation** but merely an unilateral defence against some specific kind of **environmental disturbance**. An example is the shell of a tortoise.

Of course, this type of device prevents any **interaction** with the **environment**, included some that could be useful. The decoupling capacity is generally a property of the **boundary** of the system.

0739

COUPLING (Degrees of)²⁾

J.C. LUGAN distinguishes three main types of coupling between **elements**:

"1. To a value of an **element a** corresponds one and only one value of the **element b**. We say that *a* and *b* are strongly coupled;

"2. To one constant value of the **element a** corresponds a variation of **element b** in between two **thresholds** x and y. Outside of these **limits**, the value of *a* changes. We say that the coupling is **flexible**.

"3. To a value of *a*, various or even any value of *b* correspond. We say that the coupling is weak or inexistent.

"Thus, a system is strongly **integrated** when all of its **elements** are strongly coupled. Of course, in a **set**, it may be possible to distinguish more or less **autonomous subsets** whose **elements** or **variables** are strongly coupled. This leads to the notion of **subsystem**" (1993, p.28).

0740

COUPLING (Excessive)^{1) - 2)}

Saturation of all the possible **connections** in a system.

This notion is stated by J. MELESE (1972).

A completely connected system is by necessity, totally rigid. It becomes unable to react to any **disturbance** of a new type: it cannot anymore learn or adapt.

J.L. LEMOIGNE shows that, to remain **adaptable**, the system should not be *totally* adapted. He quotes MELESE, who wrote: "**Adaptation** requires **stability**... or more precisely the presence of enough zones of **stability**, to allow for the search of local **adjustments**" (1977, p.158).

MELESE's zones of stability seem to be equivalent to KAUFFMAN's **frozen cores**.

Adaptability supposes experimentation, which implies the necessity to possess a (considerable) **variety** of potential **connections**.

→ **Frozen Core**

0741

COUPLING (Loose)^{1) - 2)}

A condition in systems by which **change** in one **part** does not generate necessary any **predictable changes** in all others.

Loose coupling may imply:

- a **discontinuous**, on-and-off **interrelation** between some **elements**
- the outright absence of **connexions** between some **elements**
- **connexions** triggered only when some **threshold of activity** is crossed.

Applying this idea to **organizations**, J.A. JOHANNESSEN and A. HAUAN make the following complementary statements:

"In order to change a tightly coupled system, a device must be implemented that makes the **parts** of the system where **changes** are most wanted more loosely coupled, thus creating "shock waves" that stir up the **patterns** of relations" (1992, p.186).

0742

COUPLING (Structural)¹⁾³⁾

The recurrent and typical **interactions** between a biological system and its **environment**.

Structural coupling may imply two different types of relationships. F. CAPRA explains this in the following way: "Kicking a stone and kicking a dog are two different stories, as G. BATESON was fond of pointing out. The stone will *react* to the kick according to a **linear chain** of **cause** and **effect**. Its **behavior** can be calculated by applying the basic laws of Newtonian mechanics. The dog will *respond* with structural **changes** according to its own nature and (**non-linear**) **pattern** of **organization**. The resulting behavior is generally unpredictable" (1997, p. 219).

This means that the dog *may* growl, bite, moan, crouch, or run.

This possibility of various alternative behaviors, present both in dog and man introduces the possibility of different **chains of events** in the ongoing **interactions** between both...in an ongoing **process**. Among human beings this opens the way for example to "**conversation**" in Pask's sense.

Accordingly, in the **autopoiesis theory** of the **observer**, the relation of the **organism** with its **environment** is seen as an endless sequence of **experiences** made by the organism, not in terms of **stimuli** from an objective external **reality** registered merely in a passive way, but as a kind of reactive internal reorganization within the limits of already existing **structures**. Whatever these may be in terms of **brain** histology and/or **neuronal connections**, it is clear that each individual constructs his/her own **frames of references**, from his/her birth on (be it the technique of bicycling, or the **rules of a language**).

As a result of this **structural coupling**, these internal **frames of references** are internally re-organized, but still as **self-reproducing structures**.

Structural coupling is specially significant in conversation between observing systems. In MATURANA and VARELA's terms (as quoted by S. BRIER - 1995, p.7): "In the coupling, the autopoietic conduct of an **organism A** becomes a source of deformation for an organism B, and the compensatory behavior of organism B, in turn, as a source of deformation for organism A, whose compensating behavior acts again as a source of deformation of B, and so on recursively until the coupling is interrupted".

Structural coupling is now incorporated in **systemic familiar therapy**. It could even possibly be applied to economic and **social systems**. Even binary stars systems are structurally coupled!

→ **Constructivism; Eigen behavior; Eigen values; "Reality" (Riddle of); Recursivity; Structural coupling**

0743

COUPLINGS between two elements²⁾

The following figure, as drawn by George KLIR (1969, p.155) shows "All possible kinds of couplings in the vector form between two **elements**" (on one type of **flow** only).

The figure shows the astounding **variety** of **processes**, most of them interactive, that can be obtained from very simple **connections** between the absolute minimum of intervening **elements**.

It also shows all that is lost by severing these **connections** by any **reductionist operation**.

see figure right

0744

CO-VARIANCE

→ **Variance (Co-)**

0745

COVERING-LAW MODEL³⁾

J. BRYANT writes: The most widely-held theory of scientific **explanation** among philosophy of science is the so-called "C-L model". which holds that a scientific explanation has the form of a **set of conditions** statements C and a set of universal laws L, which together logically implies a so-called "**explanation statement**" P, where P describes the fact to be explained, and where the fact that P is deduced from C and L constitutes the explanation" (p. 29, 1991)

Such a formulation implies a **belief in determinism**. However contemporary widened and variagated concepts of determinism seem to

weaken the general concept of the covering-law model.

This problem is also related to the ways we construct our **reference frames** and thus suppose defined views about the way we perceive and how our **brain** constructs **explanations** and **models**.

BRYANT himself discusses these problems in various sections of his book (1991)

He even says that "all philosophies are **utilitarian**, either overtly or covertly" (p. 176) while in different ways and according to different **aims**.

As a result, the "C.L. model" seems quite strong in physical sciences. This situation could possibly be more or less amended in other sciences by adding systemic **models** and **rules**, as for example, "A system is more (and less) that the sum of its **parts**"

0746

CREATION (Co-)^{1) - 2)}

The shaping of new **elements** or **structures** as a result of **interaction** between opposite forces.

According to D. SEIDEN and H. SABELLI (1992, p.720-27) any creation is co-creation, resulting from "unity, opposition and **triadic** space-like **structure**" (p.720). The basic root of co-creation is arithmetical, as "the science of **form** was born of art with the discovery of simple relations between string instruments and their sound (PYTHAGORAS), the divine proportion (FIBONACCI), the Golden rectangle (EUCLID) and other **forms** later found also in natural **processes**... These **forms** are the logic of nature, the logos (HERACLITUS) ... Small integers, non-dimensional numbers, and some geometrical **forms** are "logoi", i.e. universal **forms** embodied in **matter**... In our century, THOM developed the **theory of catastrophes** as mathematical **models** for the simpler **forms** of logoi" (Ibid).

Let us also refer to C. LAVILLE's study of **helixes** and **whorls** fed by interacting **fields** of **energy** shaping **forms** and **structures**.(1950).
→ **Toroid**

0747

CREATIVE DESTRUCTION¹⁾²⁾⁵⁾

A **process** of destruction of existing **structures** that opens the possibility for fundamental **change**.

This expression comes from economics and was introduced by the Austrian economist Joseph SCHUMPETER (1883-1950). According to Schumpeter, periodic **waves** of scientific discoveries and subsequent technical innovations trigger deep (and frequently traumatic) changes in economies and societies. Older trades and structures are destroyed and progressively replaced by new and very different ones. An example has been the destruction of older modes of transportation after the invention of the internal combustion engine (allowing the massive use of fossil **energy** of oil) and the deep **transformation** of economy, urban life and generally societies that resulted.

Moreover creative destruction appears to be a still more general **process**. Edgar Morin observes for example that all great religions of the world were predicated by one singular and exceptional individual (Moises, Jesus, Siddhartha, Mahoma, Luther). All of them triggered radical social and religious destruction and restructuring (1999, p. 79)

In fact creative destruction is a universal systemic evolutive process (from cosmology to biology, to business and to **culture**) whose significance seems to remain yet insufficiently explored, understood and managed (if possible!)

0748

CREATIVITY^{1) - 2) - 3)}

The ability to organize or re-organize **elements** into new complex **forms** and/or **processes**.

M. MARUYAMA offers the following systemic-cybernetic views about creativity: "It is a fallacy to equate creativity with capriciousness. A symphony is the opposite of **random noise**. Creativity involves the development of **patterns**, **differentiation** and **structure**. This is possible by means of **differentiation-amplifying mutual causal processes**..." (1979, p.210).

These **processes** are characterized by a well defined initial **situation**, the existence of different types of **elements** and of development **rules**. These conditions seem indeed to be the real bases of human, artistic (f. ex. musical, pictorial or poetic), scientific and technical creativity.

Such creativity is possible only in a minimally **constrained** and **structured conceptual space**. It can operate through the mechanism of **association** of two **conceptual matrixes**: A. KOESTLER's "**bisociation**". This author explains: "The basic **bisociative pattern** of the creative **synthesis** (is) the sudden interlocking of two previously unrelated skills, or **matrices** of thought" (1975, p.121).

H. ODUM offers another interesting angle: "Creative thinking requires an effectively motivated **random-thought generator** plus a well-developed **truth-reward response**" (1971, p.155).

Such a **concept** can be generalized in the following way: Creative **evolution** requires an effective **random-variety generator** plus a well-developed **fitness-reward response** device. This could even make the way easier for intelligent artifacts **evolution**.

Creativity involves, moreover, in D. BOHM and F.D. PEAT words: "... an extremely perceptive state of intense passion and high **energy** that dissolves the excessively rigidly held assumptions in the tacit infrastructure of commonly accepted **knowledge**" (1987, p.38).

The same authors observe that creativity can easily become blocked: "Basically the setting of **goals** and **patterns** of **behavior** which are imposed mechanically or externally, and without understanding, produces a rigid **structure** in **consciousness** that blocks the free play of thought and the free movement of awareness and attention that are necessary for creativity to act" (p.231).

Creativity is frequently stifled in this way by the imposition of excessive **constraints** in the very **process** of education. (The only necessary **constraints** in any system are those necessary for its **entification** - i.e. the definition of its **organizational closure**). Conceptual **order parameters** are necessary as **frames** for creativity, but excessively **constraining** ones kill it.

The same **situation** is also encountered in **human organizations** and in cultures, where **sclerosis** sets in when the **rules** become too numerous, too formal and finally downright oppressive.

As creativity supposes at least a reorganization of **conceptual space**, and sometimes the very creation of a new one, it is frequently not understood and rejected, at least for some time. This situation affected and still affects the creative work of the founders of systemics.

Many other stimulating insights in this subject, have been offered by M. BODEN (1990).

0749

CREDIT ASSIGNMENT¹⁾⁵⁾

In **rules based** adaptive **systems**, as for instance **pattern recognition machines**, but also, in a way more difficult to put in evidence, in biological and probably social systems, there is a constant need to evaluate the relative success of the **rules**. J. HOLLAND calls this **process** "credit assignment" and discusses it as follows: "Credit assignment is not particularly difficult where the **situation** provides immediate reward or precise **information** about correct **actions**. Then the rules directly involved are simply strengthened. Credit assignment becomes difficult when credit must be assigned to early acting rules that "set the stage", making possible later useful actions. Stage setting moves are the key to success in complex situations, such as in playing chess or investing **resources**. The problem is to credit an early action, which may look poor (such as the sacrifice of a piece in chess) but which set the stage for later positive actions (such as the capture of a major piece in chess). When many rules are active simultaneously, the problem is exacerbated. It may be that only a few of the early acting rules contribute to a favorable outcome, while others, active at the same time, are ineffective, or even obstructive. Somehow, the credit assignment **algorithm** must sort this out, modifying rule strengths appropriately.

"Credit assignment in classifier systems is based on **competition**.... That is, when a rule wins the competition, it actually "pays" its bid to the rule(s) that sent the **message(s)** satisfying its conditions. The rule acts as a kind of go-between or broker in a **chain** that leads from the stage-setting situation to the favorable outcome" (1992, p.176-7).

→ **Paralled distributed processing**

0750

CREEPING PROBLEMS¹⁾⁴⁾

Problems that are "the result of **long-term**, low-grade, and slow-onset **cumulative processes**". (M.H. GLANTZ, p.12).

GLANTZ adds, significantly, with more specific reference to **environmental** problems: "Creeping ... problems cut across academic disciplines, political **ideologies**, continents and **cultures**"

And "Incremental **changes** in environmental conditions accumulate over time with the eventual result that, after some **threshold of change** has been crossed, things "suddenly" appear as major degradation"...

"Creeping... problems thus change the **environment** in a negative **cumulative** and, at least for some **period of time**, invisible way. Both governments and individuals tend to continue to view their "usual activities" as acceptable".

A further trap is that: "Scientific **uncertainty** can also foster inaction" (Ibid). It can even be used by pressure interest **groups** in order to block needed **adaptations**.

→ **Change (Rates of); Effect (Delayed); Risk makers**

0751

CRISIS^{1) - 2)}

"Any sharp **transition**, any **changes** perceived by people as a **disturbance of continuity**" (A. BOGDANOV, (1921), 1980, p.229).

BOGDANOV distinguishes "C Crises", i.e., conjunctive or joining" and "D Crises, i.e., disjunctive, or separating".

He adds: "In essence, any **conjunction** begins with crisis C, the break-up of **boundaries**, and any **disintegration** of a complex originates from crisis D" (1980, p.235).

BOGDANOV admits however that in reality both types of crises are generally present under the form of "... a chain of elementary crises of both types" (Ibid).

In most cases, a destructive **phase** precedes a constructive **phase**: it is necessary that the older **structures** and **networks** break up in order to allow for some type of restructuring.

As observed by J. CALHOUN man is a crisis-provoker, probably the greatest ever.

0752

CRISIS SYMPTOMS IN HUMAN SYSTEMS⁴⁾

W.H. HARMAN characterized as follows the main symptoms of crisis in contemporary **human systems**:

" - **Interconnectedness**, so that laissez-faire approaches are less workable.

"- Reduction of geographical and entrepreneurial frontier opportunities.

"- Approaching **limits** of natural **recycling** capabilities.

" - Sharpened **dichotomy** between "employed" and "unemployed" (e.g. virtual elimination of the small farmer, partially or sporadically employed)

" - **Transition** from a basic condition of labor scarcity to one of job scarcity

" - Approaching **limits** of some **resources** (e.g. natural gas, domestic petroleum - i.e. from U.S. wells, fresh water)

" - "Faustian powers" of technology and industrialization that have reached the point where they can have a major impact on the physical, technological, sociopolitical and psychological **environment**

" - Expanded political power of labor which, forcing industrial wages to follow increasing productivity, constitutes an inflationary factor

" - More adequate supplying of deficiency needs (improved diet, material advance) plus more education, resulting in higher expectations and keener **perception** of the gap between actualities and potentialities" (1972, p.88).

This impressive 1972 list is still more valid in 1996. Some more items could be added:

- The still largely uncontrolled demographic **explosion** which is imposing a growing **strain** on all **resources**, renewable or not.

- Colossal squandering of **resources** in military spending and the resulting destructive **conflicts**.

- The general trend toward deficit spending at every **level** of public administration, with a global inflationary **effect**.

- The growing volatility of the world monetary and financial system, resulting from the newly worldwide **interconnection** of markets.

- The growing impact of clandestine and illegal business (drugs, bribes, etc.) which introduces an uncontrolled **instability** factor in economy and politics.

0753

CRITERION^{2) - 3)}

A **rule** or **standard** used to take **decisions**, emit opinions or define **categories**.

Any criterion is, of course, relative to the aims or conditions of its application. For example, we may favor a highly productive maize for economical reasons, but it may be at the same time highly susceptible to pests, or not well adapted to some natural conditions, as for example drought.

Criteria relative to systems **classifications**, or recognition of **structures** and **processes**, are of utmost importance for systems research and its **epistemological** foundations. They should always be enounced as clearly as possible.

A good example is the use of some kind of **rules** to define the **boundaries** of a system, in a more or less precise way.

0754

CRITICAL DIMENSION

→ **Size (Critical)**

0755

CRITICAL EFFECT¹⁾²⁾

An effect in a **process** which significantly changes the course or even the nature of the process.

In some cases the critical effect can either put an end to the process and eventually damage or destroy the system that depends on it.

Any critical effect corresponds to an **over-shooting**, i.e. the crossing of the **threshold** at which the process or systems loses its **dynamic stability** and turns totally **irreversible**. An example is the rupture of an aneurism, the effect resulting from a peak of blood pressure (the immediate **cause** within a protracted arterial degradation process)

The sudden effect is so dramatic that it end the very process that produced it, and initiates the total **destruction** of the concerned **living system**.

It is the case of the "camel's broken back" in the popular saying: the camel is doomed.

Epoch making historical **events** are thus considered because they usher new and very different social and political processes, i.e. while being results of anterior sequences, they mark a significant **discontinuity**.

→ **Chaos; Destructuration; Disasters; Disintegration; Disturbance; Emergence; Node (Critical); Nucleation mechanism**

0756

CRITICAL EVENT²⁾

An event "which occurs at a point of **instability**" (I. PRIGOGINE and P.M. ALLEN, 1978, p.48).

Such an event would be of little consequence in a **homeostatic system** adapting within its normal **limits of stability**. However, in **far from equilibrium** ones, even a very slight "push" can tip the system out of its **stability range** and bring on considerable consequences without any relation with its believed lack of importance. Turning points in **history** are frequently critical events. An example is the "Boston tea party", which ignited the American Revolution.

0757

CRITICAL FLUCTUATION²⁾

A **fluctuation** occurring very close to the **stability limit** of a system.

Critical fluctuations are closely related to the triggering of **dissipative structuration** in systems **far from equilibrium**.

0758

CRITICAL PATH^{2) - 5)}

A tree-like **network model** extended in the **time dimension**, used for the chronological ordering of a series of tasks related to a complex undertaking.

I.G. BLOOR describes the basics of the technique as follows: "Float calculations indicate where there is spare **time** in the **network** and "critical path" highlights which particular sequence of activities within the project determines the minimum completion **time**" (1987, p.32).

These **models** are very useful to avoid contradictions or unduly slowdowns. They should however be frequently monitored and eventually adapted to new circumstances that may appear.

0759

CRITICAL POINT²⁾

A point where the **behavior** of the system changes significantly.

R. THOM uses it as a synonym for **singularity** (1993, p.147). Another very close meaning is that of "**threshold**".

K.DE GREENE makes this very significant comment: "Near critical points, the system acts as a **whole**"

0760

CRITICAL SLOPE²⁾

The particular value of the slope of a pile of loose **homogeneous** material, at which **instability** sets in.

This critical value is reached by progressive **addition** of material to the pile. If further grains are added, the surface grains will slide off and leave the slope unchanged.

The angle made by the slope and the flat base of the mound is called "angle of repose".

Critical slopes are proper of mounds of materials devoid of viscosity. Any degree of viscosity allows for the **accumulation** of **stress** and creates a potential for **runaway events**.

0761

CRITICAL STAGE²⁾

The moment at which some system's **function** either becomes controlled by a countervailing **process**, or undergoes a **runaway process** through unchecked **growth** towards **collapse**.

Critical stages, characteristically, are not perceived by "**linear**" thinkers. As a result, **collapse** is upon them before they realize that it is going to happen and they are totally unable to correct course before it is too late.

Growth functions can generally be modeled by **logistic** curves, where the critical stage appears as an inflexion point. However, such a **model** implies the understanding of the existence of a potential braking **process**, which may be natural or purposely introduced.

0762

CRITICAL STATE²⁾

A **metastable state** in a **composite system** such as a small **perturbation** may (or not) induce a giant **fluctuation** or **runaway event**.

After any **perturbation** (strong or weak), a **composite system** tends to return its critical state, which is characterized by **fluctuations** commanded by a **flicker noise** such as small **fluctuations** are quite frequent and readily **predictable**, while giant ones are rare and quite **unpredictable**.

Good examples are the small **fluctuations** in stock markets as opposed to the great crashes, or the small quakes as opposed to great destructive seisms.

0763

CRITICAL STATE (Sub , super-)²⁾

In **composite systems**, the subcritical states do not allow for a significative **propagation** of some local **perturbation**, obviously because the **clusters** generally are not linked.

In the critical state, the **linkages** lead to a considerable **propagation** of the initial **perturbation**.

In the supercritical states, the **perturbation** propagates itself to most of the system (sudden global chain reaction or **runaway event**).

0764

CRITICAL VALUE^{1) - 2)}

A **parameter** value bringing about a sudden **change** in a **process** or in the **state** of a system.

Critical values are more or less easy to determine and to measure in physical and biological systems. In **ecosystems**, it is already more difficult to find out what exactly should be measured.

Critical values also obviously exist in economic and **social systems**: Their crossing leads for example to **runaway** inflation, devaluations of currencies, revolutions, wars and empires **collapses**. However, the sensible **parameters** themselves must first be discovered, which is no mean task.

0765

CRITICALITY^{1) - 2)}

"Characteristic of a system where the individual **degrees of freedom** keep each other in a more or less stable balance, which cannot be described as a "**perturbation**" of some decoupled **state**, nor in terms of a few collective degrees of freedom" (P. BAK. C. TANG & K. WIESENFIELD, 1988, p.364).

The authors give as an example: "...ecological systems (which) are organized such that the different species "support" each other in a way which cannot be understood by studying the individual constituents in isolation. The same in-

terdependence of species also makes the **ecosystem** very susceptible to small **changes** or "**noise**". However, the system cannot be too sensitive since then it could not have evolved into its present **state** in the first place. Owing to this **balance** we may say that such a system is "critical"... this criticality can be put on a firm quantitative basis" (Ibid).

Further on, the authors state that this class of **composite systems** "has a specific temporal fingerprint, namely "**flicker noise**"... characterized by **correlations** extended over a wide range of **time scales**, a clear indication of some cooperative effect".

Flicker noise is in fact not **noise** but reflects the intrinsic **dynamics** of **self-organized** critical systems" (Ibid)

"Another signature of criticality is spatial **self-similarity**" (Ibid).

Thus criticality is characteristic of not strongly **integrated systems** (as for example ecological or climatic ones) or almost **homogeneous** systems (i.e. with a very limited number of classes of **components**).

It seems related to countervailing statistical **regulations** which maintain the **composite system** within a **channel** of dynamic but turbulent **stability**, which evokes also the concept of **chaotic attractor**.

Note: In a more recent paper, P. BAK (with K. CHEN) use the label "**composite system**" in lieu of "**dynamic system**" which seems more adequate. In this dictionary we also use the expression: "Almost **homogeneous** system".

→ **Flicker noise**

0766

CRITICALITY AND PERCOLATION^{1) - 2)}

While criticality in a **composite system** corresponds to its tendency to turn back to a defined **critical state** which acts as an **attractor** (BAK et al., 1988, p.365), conversely percolation corresponds to its tendency to **runaway behavior** when a **percolation threshold** is reached.

This is made clear by P. BAK, C. TANG and K. WIESENFIELD who write: "The system will become **stable** precisely at the point when the **network** of minimally stable **clusters** has been broken down to the **level** where the **noise signal** cannot be communicated through infinite distances" (Ibid, p. 367).

Most of the **percolation processes** tend to spend themselves quickly because they destroy their own conditions of permanence. For example, a **population** crash is the customary result of a **population** explosion. The **composite system** whose this **population** constitutes a class of **elements** tends to go back to its **critical state**, which is thus "self-organized". It is in this case that "the **network**... has been broken down to the **level** where the **noise** cannot be communicated through infinite distances" (Ibid).

Obviously the **percolation threshold** of the **composite system** is closely related to its **critical state** "in which minor **events** can cause chain reactions of many sizes" (P. BAK & K. CHEN, 1991, p.32). A **percolation event** is probably a **runaway fluctuation** initiated in favorable conditions by a small one.

0767

CRITICALITY (Self-organized)^{1) - 2)}

Condition of a "dynamical system with extended spatial **degrees of freedom** in two or three dimensions" which "naturally evolves into a self-organized **critical state**" (P. BAK, C. TANG & K. WIESENFELD, 1988, p.365).

The authors state: "By self organized we mean that the system naturally evolves to the **state** without detailed specification of the **initial conditions** (i.e. the **critical state** is an **attractor** of the **dynamics**). Moreover, the **critical state** is robust with respect to variations of **parameters**, and the presence of quenched **randomness**" (Ibid).

However more recently P. BAK and K. CHEN state; "...**composite systems** may never reach **equilibrium** but instead evolve from one **meta-stable state** to the next" (1991, p. 26). They add: "During the past four years, experiments and **models** have demonstrated that many **composite systems** at the heart of geology, economy, biology, and meteorology show signs of self-organized criticality. These insights have improved our understanding of the **behavior** of the earth's crust, stock markets, **ecosystems** and many other **composite systems**" (Ibid).

Self-organized criticality has two "signatures" or "fingerprints" in P. BAK's and al. terms:

- a spatial ones which appears as a **fractal structure** specified by a **power-law**
- a temporal one which corresponds in each case to a specific **flicker-noise**

These abstract explanations become clearer when connected with ASHBY's concepts of **ultrastability**, non determined **transformation** and **transition's probabilities matrix**, all related to **composite systems** (See his "Introduction to Cybernetics").

St. KAUFFMAN uses the criticality model in the co-evolution **dynamics of populations** (1993, p.256).

P. BAK comments: "... regularity of **catastrophic events**, **fractals**, **1/f noise**, and **Zipf's law** - are so similar, in that they can all be expressed as straight lines on a double logarithmic plot, that they make us wonder if they are all manifestations of a single principle....- Maybe self-organized criticality is that single underlying principle.

"Self-organized **critical systems** evolve to the complex **critical state** without interference from any outside **agent**.

The **process of self-organization** takes place over a very long transient **period**. Complex **behavior**, whether in geophysics of biology, is always created by a long **process of evolution**. It cannot be understood by studying the system within a **time frame** that is short compared with this evolutionary **process**. The phrase "you cannot understand the present without understanding **history**" takes on a deeper and more precise **meaning** (1996, p.31).

BAK also observes that "self-organized criticality can actually be thought of as the theoretical underpinning for catastrophism, the opposite philosophy to gradualism" (Ibid, p.131).

Both views are useful in their own way, for instance in **evolution theory**. BAK writes: "If the theory of self-organized criticality is applicable, then the **dynamics of avalanches** represent the link between DARWIN's view of continuous evolution and the punctuations representing sudden quantitative and qualitative **changes**. Sandpiles are driven by small changes but they nevertheless exhibit large catastrophic **events**" (Ibid).

0768

CROSS FALSIFICATION

→ **Falsification (Cross)**

0769

CROSS LEVEL RESEARCH (in living systems)^{1) - 3)}

J. MILLER, who has actively promoted cross-level research as a general **systems methodology**, proposes three degrees of generality for it:

"The first predicts that a formal identity and/or disidentity is present across individual systems of the same species or type. A research that tests the hypothesis that individual rats differ among themselves in the **rates** at which they characteristically learn to run mazes is of that sort.

"Cross-type or cross species generalization is the second degree of generality of hypothesis. Such **generalizations** are more powerful than the first sort. Also they involve more **variance**. Research in comparative anatomy, comparative physiology, comparative psychology, and comparative sociology is of that sort.

"The relative **size** of skulls of rats, cats, dogs, dolphins, apes, and human beings, for instance, can be compared with the average measures of intelligence of each species to confirm the hypothesis that animals with larger skulls - and larger **brains**- have greater cognitive capacity. Of course there is also variance among individual members of a single species.

"The third type of scientific **generalization** is from one **level** to another. These cross-level **generalizations** will, ordinarily, have greater **variance** than the other sorts since they in-

clude **variance** among types and among individuals. They can, however, be made. They can enable insights and discoveries made at one **level** to give rise to general principles which apply to multiple **levels of living systems** and, in some cases, to nonliving systems and technologies as well. As **understanding** of systems in general increases, fragments of **knowledge** may coalesce into **patterns** and science as a whole may become more coherent. Indeed, evaluating the validity of cross-level hypotheses may become a very significant innovation in the study of **living systems**.

"Scientists undertake cross-level research less frequently than cross-individual or cross-type. There are a number of reasons for this. Scientists are trained to be specialists in one or another of the many disciplines and subdisciplines into which the subject-matter of science is traditionally divided. They limit the scope of their expertise on the grounds that one person cannot be informed in depth and expert on a broader range of **phenomena**. The usual **patterns** of rewards to scientists, including academic promotion and tenure, recognition in national scientific societies, grant awards, prizes, and so forth reinforce **specialism**. What is more, the traditional cautiousness of scientists makes them skeptical of any **generalization** from, say, a **cell**, to a system as different as an **organism** or a society. Scientists working at one **level of living systems** are rarely current with the literature at other **levels**. This is demonstrated by the paucity of references to researchers at other **levels** in the texts or bibliographies of scientific papers. As a result, when a scientist discovers a principle at one **level**, he typically does not think it likely enough to be relevant to another **level** to take the trouble to find whether similar principles have been reported in the literature at other **levels**.

"General **living systems theory** in no way denies the importance of specialists' **knowledge** or the advancement of **understanding of phenomena** in limited scientific areas. Specialized research will properly continue to be the chief means by which science advances. At the same time, however, there should be studies of generalities or similarities, as well as differences, among different classes of **phenomena**" (1986, p.74-76).

0770

CROSSBAR²⁾

The **connection mode** in which every **element** can be connected with every other one.

Telephone nets are constructed in this way. See "**connection modes**".

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0771

CROSS-DISCIPLINARY ^{1) - 3)}

A basic characteristic of systemics, which allows the uses of **analogies**, **homomorphisms** and **isomorphisms** between different disciplines as a **methodology**.

According to G. KLIR, this characteristic implies at least three important consequences: "First, systems science **knowledge** and **methodology** are directly applicable in virtually all disciplines of classical science. Second, systems science has the **flexibility** to study systemhood properties of systems and the associated problems that include aspects derived from any number of different disciplines and specializations of classical science. Such cross-disciplinary systems and problems can thus be studied as **wholes** rather than collections of the disciplinary **subsystems** and subproblems. Third, the cross-disciplinary orientation of systems science has a unifying influence on classical science, increasingly fractured into countless numbers of narrow specializations, by offering unifying principles that transcend its self-imposed **boundaries**. Classical science and systems science may thus be viewed as complementary dimensions of modern science" (1993, p.29).

0772

CROSS-IMPACT ²⁾

The reciprocal influence of one **event** or **process** on other ones.

While direct **interactions** are evident and generally taken into account, many other ones which are not so obvious, are frequently ignored or neglected. A **graph** or **matrix** of the various intervening **elements** or **processes** helps find out which **interactions** are effective and significant, within the totality of the possible ones.

0773

CROWD PHYSICS ²⁾⁵⁾

The **rules** of spontaneous self-ordering of a great number of individual **elements** in movement within a confined **space**.

This curious systemic **phenomenon** can be observed in widely different settings, as for example in heavy traffic in truncl roads, or in crowded lobbies or staircases, or in fish **schools** (spatially confined to secure better protection against predators).

It seems related to a general reciprocal collision avoidance **behavior** - combined with specific advantages of groupal **dynamics** for a better use of **energy**.

This type of behavior appears at very distinct **levels** of global **organization**.

In **BENARD's instability** and **structuration** by **energy dissipation**, it is a result of basic **thermodynamic processes**. The **BELOUSOV-ZHABOTINSKY** catalytic **reaction** is an example in chemistry, also based on **thermodynamics**.

GRASSÉ's **stigmergy** shown in termites building their mounds seems to be another example, wherein reciprocal sensorial **stimulation** starts to be a predominant factor. The shaping of locusts **swarms** from individual insects under some specific **environmental** conditions leading to crowding in a reduced space, is also an example. Somehow, as stated by von FOERSTER **order feeds on noise**" (1960, p. 31-50)

0774

CROWDING EFFECTS ^{1) - 4)}

It has been quite frequently observed that crowding in animal **populations** tends to modify the **behavior** of the individual participants and to create collective **behaviors**. In some cases these are merely gregarious, but in others they seem to lead to incipient **sociality**.

This **phenomenon** has been documented in the well known amoeba **dictyostelium discoideum**, in sponges, in schools of marine invertebrates and of fishes, in various species of locusts, in starlings, in naked mole-rats, etc...

Crowding seems to modify the reciprocal **perception** in the individuals in the crowd, through physical, biochemical, optical and other **effects** that appear to become effective only with closer **proximity**.

Crowding effects in human masses, at the physiological as well as the psychological **level** are also well established. It may even be observed in the **behavior** of drivers-vehicles systems on an overcrowded road.

Under different forms, this **phenomenon** seems to be present at the microphysical and the chemical **levels**. Its basic mechanism could be usefully researched as a genuine systemic-cybernetic **model**: a **cross-feedback process** related to high **density**.

Precursors in the study of crowding effects in human masses have been the French sociologist G.LE BON (1895, U.S. translation 1960) and the italian S. SIGHELE (1892). Crowding effects in general have been extensively researched by J. CALHOUN (1962), J.J. CHRISTIAN (1959), J. FREEDMAN (1975) and others.

The french sociologist R. BOUDON describes the effects of crowding as "perverse", which means that individual **functions** are somehow impaired when they become massively competitive. This kind of **effects** leads either to global blocking or to higher **level sociogenesis**.

0775

CRUNCH ^{1) - 2) - 4)}

A critical decrease of possible alternatives for **action** due to a reduction of available **space**, usable **resources** and or a shortening of **time limits**.

Crunches corresponds to a limitation of the systems **variety** or **diversity** both in **space** and **time**. They generally appear quite suddenly, in relation to long or **very long term** exceptional **accumulative effects**.

R. THEOBALD emphasized the importance of "decision crunches" due to accelerating **changes** in the technical and social **environment** of **human systems**. (ISSS Conf. Asilomar, 1994)

J. WEINS proposed the **concept** of environmental crunches, due to **disturbances** in **eco-systems environments**, which reduce **resources** and provoke a more intense **competition** within the system (1977, p.590-7).

0776

CUE ¹⁾²⁾

A characteristic or **signal** in a **stimulus** which implies a specific **meaning** in the **stimulus**.

Cues are related to **implicit knowledge**, as it results from anterior **learning** allowing the recall of a similar **meaning** in more or less similar circumstances.

0777

CUES (SOCIAL) ⁴⁾

Signals that the individuals may perceive as a result of the **collective behavior** of their **group**.

Social cues are obvious in practically all forms of societies, animal or human.

They are very diverse in nature: concentrated **pheromones**, collective **behavioral change**, **rituals**, ideological calls, etc.

They are kinds of **feedbacks** between the individuals and their **group**. Public opinion, for example, as in a famous engraving by A. BÖCKLIN, is a **self-reproducing fractal** monster. Every individual is imprinted in the same form by his collectivity and contributes to the permanent **reproduction** of the collective behavior, in a kind of systemic scaling **self-similarity**.

Social cues may sometimes evolve, but this **process** is generally quite slow and may be hazardous. Radical **shifts** of social clues types are very exceptional, as expressed through the famous sicilian "Gattopardo" behavior described by LAMPEDUSA: "Introducing some **change** in order to maintain things as they are"

Of course, when the social clues lose their clear **meaning**, the society is in great danger to lose its bearings.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0778

CULTURAL FEASIBILITY→ **Feasibility (Cultural)**

0779

CULTURE⁴⁾

The **set of values** and **norms** proper to a social system.

These **values** and **norms** act as collective **order parameters**. They include beliefs (religious, aesthetic, ethical, philosophical), basic **concepts**, law systems, political ideologies, technical practice, dominant economic attitudes, etc...

The basic **values** and the resulting adaptive **norms** correspond to the **autopoietic** character of a given **sociosystem**, which must however adapt to internal and **environmental change**. It strongly polarizes nearly all the individuals in the system, through reciprocal **behavioral constraints** and, in turn, generates the **behavior** and attitudes needed to maintain its global **coherence**, **efficiency** and in some extreme cases secures its very **survival**.

When the **values** and **norms** are starting to crumble, the **sociosystem** generally finds itself in the middle of a terminal **crisis** and/or facing a critical transition toward other **forms** and ways.

Culture seems to have ethological roots in social mammals and birds, and even possibly biochemical ones as in insect societies, and amoeba.

0780

CULTURES AS SYSTEMS⁴⁾

The common acceptance by a numerous group of people of a set of **values** and **norms** tend to create a dynamically stable entity which maintains itself with recognizable characteristics during quite a long **span** of **historical time**.

It becomes conceptually acceptable to speak of "cultural systems". Their main characteristics are:

- each one offers basic features, **values**, **beliefs** and **norms**, a **language**, specific aesthetics, a folklore
- two or more different cultures may find it quite difficult to communicate
- a cultural system generally exists in more or less well defined and stable spatial **boundaries**
- the values and norms of the culture are transmitted from one generation to the following by a kind of psychological imprinting, which guarantee their survival ("**historical consciousness**")
- cultures evolve and finally tend to decay and disappear; but may leave traces and thus contribute to the inheritance of new cultures in the making

- individuals pertaining to a culture adapt themselves very uneasily in another one and are also frequently discriminated (nationalism, religious fanaticism, racism, etc) (R. ARON, 1961)

Of course, a member of a cultural system views his/her systems in function of the received imprinting, from which it is very difficult to escape

→ **Aura; History (Sistemic)**

0781

CULTUROCENTRISM¹⁾⁴⁾

The mental attitude and worldview that tends to interpret **facts** or **issues** from the sole- and generally narrow- viewpoint of the **values** and **norms** of one's own **culture**.

Culturocentrism restricts very seriously (and at times, blocks) our **understanding** of "aliens" (the "barbaroi" of the old Greeks, a word whose present **meaning** reflects our obvious own culturocentrism)

Such attitude derives easily into deep misunderstandings, mistrust, hostility, intolerance, fanaticism and even criminal **behavior**. As we receive kind of an **imprinting** from our own culture, it is very difficult, however, to escape from culturocentrism.

This kind of bias seems also to exist in our understanding of historical cultures: a contemporary man or woman has probably a quite fanciful view of Middle Age life for instance.

One of the most useful goals of science in general and systemics in particular could be the construction of a world-widely accepted consensual understanding of some general **concepts** and models, to which cybernetics and systemics could make a valuable contribution.

→ **Anthropocentrism**

0782

CURVE (Involving)²⁾

A curve representing a **long-** or very **long-term process**, which includes more or less **self-similar** curves at **medium** and/or **short term**.

This notion was introduced by F. ZWICKY (1971) for use in **forecasting**.

It was however already implicit in K. **WEIERSTRASS's** renormalization **function**. It has also been used by F. MEYER (1954) to emphasize the **evolutional acceleration process**.

The subject could be related to **ergodicity**, **deterministic chaos** and, possibly to a **fractal concept of time**.

0783

CUSP²⁾

"Development of a **bifurcation** in which one of the **two states** is reached from the other by the **action** of an external force" (R. FIVAZ, 1991, p.31).

This is one of the elemental **catastrophes** described by R. THOM.

0784

CYBERNATION¹⁾

"The ongoing **process** of **regulation** and **control**".

Cybernation implies maintaining the system within some defined **limits** by the programmed use of **positive** and **negative feedbacks**, according to incoming **inputs**.

0785

CYBERNETICS^{1) - 3)}

1) "The field of **control** and **communication** in the animal and the **machine**" (N. WIENER, 1948, p.19).

N. WIENER's original view is in fact quite mechanistic and corresponds to what became known as **1st Cybernetics** or **Cybernetics of the 1st order** (The latter, including **2nd Cybernetics**).

2) "The study of systems that are open to **energy** but closed to **information** and **control** - systems that are **information tight**" (W.R. ASHBY, 1956, p.5).

ASHBY's view is quite close to WIENER's: "Cybernetics deals with all forms of **behavior** insofar as they are regular, determinate or reproducible... What cybernetics offers is the framework in which all individual **machines** may be ordered, related and understood" (p.2).

WIENER's and in a lesser measure ASHBY's viewpoint, have aroused considerable resistance in human sciences researchers.

ASHBY himself however also wrote: "Cybernetics treats, not things, but ways of behaving. It does not ask, "What is this thing?" but "what does it do?"...It is thus essentially **functional** and **behavioristic**... The materiality is irrelevant, and so is the holding or not of the ordinary law of physics" (1956, p.1).

And, moreover: "The truth of cybernetics are not conditional on their being derived from some other branch of science. Cybernetics has its own foundations" (Ibid).

German cyberneticians, at least until 1970 preferred a quite formal view, as may be appreciated in the four following definitions by K. STEINBUCH, H. FRANK, F.von CUBE and G. KLAUS:

3) "Science of informational **structures** in technical and non-technical domains" (basically concerned with **data** treatment) (STEINBUCH, 1955, p.325).

4) "The theory and technique of systems which transform **messages**" (FRANK, 1969, p.30).

5) "(the) mathematical and constructive treatment of general **structural relations**, **functions** and systems" (von CUBE, 1967, p.11-16).

6) "The theory of interconnectedness of possible dynamic **self-regulated** systems with their **subsystems**" (KLAUS, 1965).

The Russian cybernetician V.M. GLUSHKOV proposed in 1966 a quite similar technical concept of cybernetics:

7) "(the general theory of the **transformation of information**, and ... the theory and principles of building various transformers of **information**" (1966).

GLUSHKOV included in his book theories of **algorithms**, of discrete **automata**, of **self-organizing systems** and of mathematical logic. V.G. DROZIN observes that "... its contents overlap somewhat with that of Computer Science as taught in our country" (i.e. U.S.) (1976, p.30).

8) "Discipline which studies **regulations** and **communication** in the living beings and the man-built **machines**" (J.de ROSNAY, 1975, p.93)

Quite significantly, de ROSNAY uses the word "**regulation**" in lieu of "**control**" used by WIENER. As a biologist he is more attuned to the non intentional aspect of **regulation**. This seems better if one remembers that many biologists, psychologists and sociologists reacted negatively to cybernetic "**controls**", that they considered a mechanistic **reductionism**, apt moreover to induce possible manipulations of human (and animal) **behavior**.

On the other hand, de ROSNAY adds: "A more philosophical definition, proposed by L. COUFIGNAL in 1958, views cybernetics as "the art to ensure efficacy in action". The word "cybernetics" has been reinvented by WIENER in 1948, from the greek word "kubernetes", which means pilot or steering wheel. One of the very first cybernetic mechanisms of velocity **regulation** in a steam machine, invented by James WATT and Matthew BOULTON in 1788, was called "governor"... Cybernetics has thus the same root as "government": the art of managing and lead highly **complex systems**. (Ibid).

From 1960 on, a less mechanistic view of cybernetics started to emerge, with St. BEER, G. PASK, H.von FOERSTER, M. MARUYAMA, H. MATURANA, and other researchers.

According to St. BEER: "... cybernetics studies the **flow of information** round a system, and the way in which this **information** is used by the system as a means of controlling itself: it does this for animate and inanimate systems indifferently. For cybernetics is an interdisciplinary science, owing as much to biology as to physics, as much to the study of the **brain** as to the study of computers, and owing also a great deal to the formal **languages** of science for providing tools with which the **behaviour** of all these systems can be objectively described" (1966, p.254).

One wonders if BEER would still have used the word "objectively", since it is now generally admitted that scientific **knowledge** may some-

times be "falsified" (POPPER), and results of a **consensual process** through **conversation** (PASK). Of course and notwithstanding, we still can safely *postulate* the existence of an objective reality and all this does not impair the usefulness of the cybernetics' **models**.

Further along BEER adds: "... cybernetics is precisely *about organization* – for this is the medium through which **control** is exercised. Therefore cybernetics may also be defined, as it has been by certain Russian writers as the science of effective **organization**" (Ibid., p.425).

In any case, BEER's view is not mechanistic: "Cybernetics begins where the possibility of **algorithmization** of the controlled system ends" (Quoted by V.G. DROZIN, 1976, p.28).

According to K. KRIPPENDORFF: "In cybernetics, theories tend to rest on four basic pillars: **Variety, circularity, process** and **observation**" (1986, p.20).

As stated by this author, **variety** is closely related to **information, communication** and **control**. **Circularity** is a necessary result of **feedback**, and leads to **autopoiesis**. **Process** is implied in **feedback, communication, regulation** and **control**, and **observation** is the basic condition for **decision making** and **control**.

Historical note: The word cybernetics was used for the first time by PLATO in the sense of "pilot's craft" or "the art of leading men". R. VALLEE states that, in 1834, the french physicist AMPERE used it in his "Essai sur la philosophie des sciences" to name the "study of the means of governing".

VALLEE adds: "In 1843, TRENTOWSKI did the same with the word *kibernetiki* in a book on **management** written in Polish", and still: "(W.S. McCULLOCH) liked to put cybernetics under the aegis of DESCARTES who proposed in 1664, an interpretation of cybernetical type, involving **feedback**, within the framework of his theory of nervous **transmission**. On the contrary WIENER considered LEIBNIZ (1646-1716) as the patron of cybernetics" (1993, p.84).

Table: see entry **Cybernetics (First and Second Order)**

Author	First order cybernetics	Second-order cybernetics
WIENER	mechanism	structural couplings
von FOERSTER	cybernetics of observed systems	cybernetics of observing systems
PASK	the purpose of a model	the purpose of a modeler
VARELA	controlled systems	autonomous systems
UMPLEBY	Theories of social systems	Interaction between observer and observed
UMPLEBY		Theories of the interactions between ideas and societies .

Other important precursors of cybernetics were the Russian BOGDANOV (1921), the Rumanian Stephan ODOBLEJA (1938), as well as W. CANNON (1932). The French biologist P. VENDRYES discovered independently the mechanisms of **homeostasis** and **autonomy** (1942).

In fact, the cybernetic **model** is implicit in numerous **concepts** and artefacts, since Antiquity.

0786

CYBERNETICS (First and Second Order)¹⁾

Stuart UMPLEBY explains as follows the differences between Cybernetics of the 1st and 2nd order.

"Cyberneticians have distinguished the recent work in cybernetics on **constructivist epistemologies** from the earlier work on **control** systems by using the term "second-order cybernetics". This term was first used by Heinz VON FOERSTER, who defined first-order cybernetics as the cybernetics of observed systems, whereas second-order cybernetics is the cybernetics of the observing systems (von FOERSTER, 1979). von FOERSTER intends the term "observing systems" to be interpreted in two ways: either systems that observe or the act of observing systems. Gordon PASK made a similar **distinction** when he defined first-order cybernetics as dealing with the **purpose** of a **model**, whereas second-order cybernetics deals with the **purpose** of the modeler. Francisco VARELA suggested that first-order cybernetics is concerned with **controlled** systems, whereas second-order cybernetics is concerned with **autonomous** systems" (1990, p.112).

S. BRIER enounces as follows the program of 2nd order cybernetics: "The basic concepts developed...are **autopoiesis**, closedness, **Eigenvalues** and the idea that the production of **information** is internal to the **autopoietic system**, and that **perception** and **communication** are based on **structural couplings**"(1995, p. 6)

Closedness should be understood as **organizational closure** obtained through **recursivity**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

S. UMPLEBY proposed "two additional conceptions of second-order cybernetics (1979). First-order cybernetics can be said to be concerned with **interactions** among the **variables** in a system, whereas second-order cybernetics is concerned with the **interaction** between the **observer** and the observed. The final definition goes beyond the one-brain problem of psychology or **artificial intelligence** and focuses instead on the **n-brain** problem of communities or societies" (p.112).

The following table gives a summary of UMPLEBY's views:

TABLE 1. Definitions of First- and Second- Order Cybernetics (p.113)

→ **Cybersemiotics**

see table page 146

0787

CYBERNETICS (First Order) or CYBERNETICS (1st)^{1) - 3)}

There is some ambiguity in these terms.

The first cybernetics is WIENER'S **control** cybernetics.

According to H.von FOERSTER, the 1st order cybernetics is the theory of **homeostatic systems**, wherein the concept of **regulation** tends to replace the one of **control**.

However, **self-regulation** already implies **organizational closure** and so, we shift to **cybernetics of 2nd order**.

WIENER himself defined Cybernetics as "**Control and Communication** in the animal and the **machine**" in the very title of his *Opus Magnum*.

The basic instrument of **control** is **feedback**, the **mechanism** used in **regulators**, which permit the monitoring of **deviations** and their subsequent correction.

This **mechanism** can be found in natural as well as in artificial systems. However, it has been discovered, at least explicitly, in natural systems, only after its discovery, use and explanation in artificial ones.

The (unconscious) discoverers of **feedback** were old-time craftsmen. The use and construction of **regulators** started to systematize from James WATT on and shifted from craftsmen to engineers.

Thus, the **concept** of **control** came to imply the idea of voluntary correction of some **deviation** and, during the last fifty years very numerous **control** devices of various types have been constructed.

The "**reliable automaton**" became the typical creation of cybernetics and its popular form, the "**robot**", imposed itself to the imagination of the man in the street. Meanwhile, psychologists, social scientists and ecologists began to mistrust this new science, whose apparent or at least potential aim was the perfect mechanistic **control** of everything, including man and

society. The Orwellian nightmare seemed suddenly possible and menacing, as well as some others, readily described by science-fiction authors.

Rigorous **planning** and Skinnerian conditioning seemed to indicate real and practical ways to this perfect **control**, dreamed of by would be perfect **controllers**.

As WIENER states: "The thought of every age is reflected in its technique" (1948, p.49 of the Hermann Edition). Obviously, **control** in its **algorithmical** sense reflects the more or less totalitarian mind and spirit (and possibly the scientific "ubris") of many mid-20th century leaders in most fields.

The study of **algorithmic control of artifacts** and **communication** devices by WIENER, SHANNON and WEAVER, TURING, von NEUMANN and others, around 1945-1960 has been the core of the first cybernetics.

The basic problem was: "How to **stabilize** systems and maintain them in as strictly possible defined **limits of behavior**".

In H.von FOERSTER words: "First order Cybernetics developed the **epistemology** for comprehending and simulating biological **processes** as, e.g. **homeostasis**, **habituation**, **adaptation**, and other first-order **regulatory processes**" (1974, p.16). This was of course quite better than the former: "How to lead a system to a final ideal and absolutely stable state". But it was still far from the **2nd. order cybernetics**, which tries to understand adaptive **autonomy** and, further, shifting **adaptability**.

W. Ross ASHBY and H.von FOERSTER started this **2nd. order cybernetics** on its way during the fifties.

As to the **runaway** and **deviation amplifying processes** resulting from non-compensated **positive feedbacks**, their study was seriously started in the sixties, especially by Magoroh MARUYAMA (1963, p.164-79), who called this, the **2nd. cybernetics** (not to be confused with **2nd. order cybernetics**).

As in the 1st. Cybernetics it is basically concerned with "the system to which is attributed qualities of objective **reality**, and to which the act of **observation** makes no difference (Of course scientists know that this is an over-simplification, but it is conveniently easy to handle)" (R. GLANVILLE, 1979, p.35).

As a result "... its shortcomings have been traditionally obscured" (Ibid).

→ "**Reality**" (**Riddle of**)

0788

CYBERNETICS (Second)¹⁾

The cybernetics of **deviation-amplifying processes**.

This development of cybernetics, centered on **positive feedbacks**, was introduced by M. MARUYAMA (1963, p.164-79, or in J. MILSUM (Ed.), 1968).

It considers the conditions that permit the **amplification** of small initial **deviations** until very considerable, and sometimes **runaway effects** are produced.

This is quite at variance with **control** cybernetics, whose aim is precisely to maintain **processes** and systems within their **stability channels**.

MARUYAMA also considers the cases where various amplifying **processes** interfere, causing progressive **structuration** (See: "**Causal process (Mutual)**")

MARUYAMA's **model** has been confirmed in a different way through I. PRIGOGINE's **dissipative structuration model**.

It is also a kind of **cellular automaton**.

0789

CYBERNETICS (Social)

→ **Social Cybernetics**

0790

CYBERNETICS (Technical)⁵⁾

Technical cybernetics is mainly concerned with the study and construction of **control** and **communication** systems.

In I.G. BLOOR's words: "As a technique it has become the **design template** for mechanical and electronic systems and latterly the **design of Management Information Systems**. Cybernetic theory requests that all **inputs** to, and **outputs** from a system must be defined or designed together with suitable "**triggers**" or **sensor mechanisms** to detect any **change in activity or response**" (1987, p.8).

The main core of cybernetic technique is the **control** device, which must monitor and measure such **changes**, compare them with specified **standards**, calculate a corrective **action** if needed and trigger it, using specific means to do so.

Communication cybernetics is concerned with the technical conditions of **coding**, **transmitting** and **decoding messages**. This includes the construction of suitable **channels**, devices to compensate **noise** and the eventual production of suitable **redundancy**.

Cybernetic technique is also implied in computer hardware and software, in **artificial intelligence** and **expert systems**, in **robotics** and **bionics**, in the new fields of **artificial life**, virtual reality and **information** "highways".

0791

CYBERNETICS (The scope of)^{1) - 3)}

G. PASK formulated the following opinions about the scope of cybernetics:

"... tough I can see the difference between cybernetics, **General Systems Theory** and Cognitive **Information Science**, I fail, completely, to see its practical significance unless a very specific piece of work is in mind; and, as a result of that, fail also to get in the least irritated if these terms are misapplied..."

"I believe that Cybernetics (and the allied sciences) are peculiarly concerned with well formed **analogies**, the manipulation of **metaphor** and the **epistemological/psychological/** social problems that attend these pursuits.

"... Cybernetic theories comment upon these **processes**, which are excluded, strictly, from consideration by the run of other sciences, except when viewed from the special perspectives of metaphysics or of **metamathematics**..."

"As a result, all Cybernetics theories are relativistic and some of the more interesting theories are also reflective (becoming "objective" only at specific points, where sharp valued independent **measurement** is possible). For example, with my psychological hat on, but still retaining a Cybernetic orientation, I insist upon *dealing with consciousness*, not *excluding it* (hence, with **self-referential** and other referential systems).

"... I am prone to regard the use of **information** measures and statistical accounts as only one (quite useful) way of dealing with the **situation**. Since such **methods** are apt to objectify the **phenomena**, I think they are somewhat overrated. The chief hazard, is the temptation to use appeals to "**complexity**" as an excuse for *not* tackling the real issue of "reflective" theories and their interpretation.

"... Amongst the more important growing points are: a) Theory of reproductive **automata**... b) The theory of metagames... c) **Fuzzy logics** and concurrent computation... d) Categorical algebras... e) Aspects of **topology**... able to accomodate or represent knowable relations and cultural **patterns**" (1973, p.5).

As to **Artificial Intelligence**, in PASK's opinion: "Perhaps the subject should be called "General Intellect" instead of **Artificial Intelligence**" (Ibid). As early as 1973, PASK perceived that the *process of learning* was of paramount importance and that it was not possible to limit the subject to "... the clever application of **problem solving techniques**" (Ibid).

According to F. ROBB, general cybernetics includes:

- **Conversation theory** (G. PASK)
- **Autopoiesis** (MATURANA and VARELA)
- **Deviation amplifying mutual causal processes** (M. MARUYAMA) (see also **2nd cybernetics**)
- **Self-organizing systems** (I. PRIGOGINE)
- **Self-steering systems**
- **Meta-system theory** (J. van Gigh)

which ROBB considers as "much intermingled streams of cybernetic thought" (1989, p. 51).

Of course, none of these concepts and theory can ignore the original basic **concepts of feedback, regulation and control**.

0792

CYBERSEMIOTICS¹⁾³⁾

A synthesis of systems theory, **second order cybernetics** and the **semiotics** of Charles S. PEIRCE (N. ORT, 2001, p. 155)

The concept has been introduced by S. BRIER (1995, p.3-14). It is closely related to biological and particularly human **communication** because:

- only organized entities (i.e. systems) are able to communicate
- **communication** needs of reciprocal **observation** in a **recursive** way
- elaborated **meanings** appear only through recurrent dialogue among living **observers**
- **signs** and **signals** are the "commodities" traded through communication, which would be impossible without this type of "currency".

BRIER writes: "Cyber-semiotics is based on different view of what a **sign** – and more specifically a **symbol** – is than the **syntactic denotative** concept of cognitive science. It is based on PEIRCE's **semiotics**" (p.6). Formerly "the mechanistic idea of reason and **knowledge** – and of **logic**, of course - has led to a simplistic understanding of how **meaning** functions in both **language** and practice. The mechanist hopes that the **causal interaction of symbols** can be explained through their **syntactic relations**" (p.5). Of course this implies **communication** without the bio-neuro-psychological presence of the **communicators**.

BRIER writes, refering himself to a text of FODOR which basically endorses the mechanist view as expressed through the recourse to purely **syntactic relations**: "There are many arguments against this. Mine are from a biological perspective. I do not think that meaning can be fully represented in a **syntactic logical** form. Meaning is very much tied to biological existence. Two important aspects of this are the dynamics of biological **organization** in relation both to **evolution** and to the **dynamics of population**. The new concepts developed within **second-order cybernetics** and **bio-semiotics**, which describe these qualities, are **autopoiesis** and **code-duality**. In this paper I want to suggest a combination of these including a semiotic approach. This what I call cyber-semiotics" (p.6).

Thus, cyber-semiotics should be understood as cyber-bio-semiotics, in which the "cyber-" aspect should not be reduced to the purely mechanistic **feedbacks** of Wienerian original cybernetics.

0793

CYBERSPACE⁵⁾

"A virtual multidimensional world created and functioning through computers connected within a large **network**" (M. BENEDIKT)

BENEDIKT writes: "Every workstation within is a window open into a world wherein distances are annulated. **Objects** seen or heard are not physical, nor even **representations** of physical **objects**. They should better be viewed as pure **data**, as a kind of raw **information**".

We are thus on our way towards a cybernetic culture, shared by all people who will, in a connected way, become users of the globally connected cyberspace which seems in the making. The consequences for future **human systems** are difficult to evaluate, but could be impressive.

0794

CYCLE^{1) - 2)}

A curve characterizing a sequence of **states** more or less periodically repeated by the system.

G. WEINBERG states: "Cycles are the signature of **state-determined behavior**. When we see a system in a **cycle**, we suspect that it may be at present uninfluenced by external factors" (1975, p.204). These cycles should be of **autopoietic** nature, i.e. a result of the self-regeneration power of the system. However, WEINBERG also admits that the system "...may be influenced by a cyclic external factor, or by an external factor that is too small to break the cycle" (Ibid).

Considered along the **time** dimension, the cycle appears as a sinusoidal **wave** with defined **period** and **amplitude**, more or less deformed by interferences or **perturbations**.

Cycles of various **periodicity** may affect a same **complex phenomenon** and eventually produce a quite irregular curve whose lecture and interpretation become very intricate. **Spectral** (also called sometimes harmonic, or **FOURIER**) **analysis** may be used as a mathematical technique to disentangle such complex curves. It should however be used carefully, because it may very well lead to the appearance of **pseudo-cycles** without any factual bases. This problem unfortunately discredited cycle theories among unaware economists, as signaled by K. BOULDING (1972).

Only **steady states systems** cover this kind of periodical **trajectories** over and over.

The main initial proponents of cycles have been the economists. Proposed economic cycles have been, as recapitulated by K. DE GREENE:

"... the KITCHIN, or business cycle, per se, of three-to-four or four-to-seven years' duration,

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Figure: see entry **CYCLE**

Cycles (Life):

From G. R. DOWLING & J. A. COOPER: 1989, p. 294

interpreted as indicating **fluctuations** in commodity inventories and employment.

"... in corresponding terms, many recognize the JUGLAR cycle of 8-10 years, representing fixed capital in the durable equipment of production;

"the KUZNETS cycle of 15-25 years, representing fixed capital in **structures** or real estate and the mix of capital and labor;

"and the KONDRATIEV cycle or **long wave** of about 45-60 years..." (1988, p.281)

DE GREENE gives very interesting precisions about the characteristics and probable causes of these four cycles. He however observes that "... confusion can arise from regarding "cyclical" as synonymous with "periodic". The intervals between "crises" are not regular; what is regular is the recurrence of prosperity, recession,

depression and revival, in that order" (Ibid).

This confusion discredited the so-called cycles theories. What was not clearly understood is that the four described cycles, together with many others (astronomical, geological, meteorological, ecological, etc...) lead finally to such intricate combinations that it becomes practically impossible to discover regularities sufficient to guarantee some measure of **predictability**. This is closely related to **chaos theory**, which emphasizes the importance of multiple and simultaneous **initial conditions** as the cause of **chaotic determinism**.

This is not to say however that the *quasi-* or *partly* cyclical character of many **phenomena** is an illusion. What remains to be discovered is a practical method to sort out – at least as

much as possible – the intricacies of complex cycles

see table left

0795

CYCLE and STRUCTURE^{1) – 2)}

D. KATZ and R.L. KAHN state that: "The problem of structure, or the relatedness of **parts**, can be observed directly in some physical arrangement of things where the larger unit is physically bounded and its **subparts** are also bounded within the larger structure. But how do we deal with social structures, where physical **boundaries** in this sense do not exist? It was the genius of F.H. ALLPORT (1962) which contributed the answer, namely that the structure is to be found in an interrelated **set of events** which return upon themselves to complete and renew a cycle of **activities**. It is **events** rather than things which are structured, so that social structure is a dynamic rather than a static **concept**" (1969, p.93-4).

The same authors added: "A single cycle of **events** of a self closing character gives us a simple form of structure. But such single cycles can also combine to give a larger structure of **events** or an **event system**. An **event system** may consist of a circle of smaller cycles or hoops, each one of which makes contact with several others" (Ibid).

In fact, any more or less **integrated system** is "social". And all structures disclose recurrent **functions**. They have thus a **synchronic** and a **diachronic** aspect.

These already older ideas heralded altogether the **organizational closure**, **autopoiesis** and **hypercycle** concepts.

0796

CYCLE (Catalytic)

→ Catalysis (self-)

0797

CYCLE (Cumulative)^{1) – 2)}

The progressive development (or **involution**) by reciprocal **feedback** of two or more **functions** or **subsystems** in a system.

According to A. LOTKA, who proposed the **concept**: "The eye and the hand have probably contributed more than any other circumstance to the **evolution** of the human mind up to its present **level**. The possession of an agile member gave opportunity for exercise of the mental faculties, this in turn reacted towards increased development of the tactile sense and manipulative skill of the hand, and so in a cumulative cycle" (1956, p.298).

This author also claims that **language** and thinking have interacted in the same mutual stimulating way.

This would be the equivalent of a virtuous circle. There seems however to exist cases where the reciprocal cumulative cycle has negative effects. It has been conjectured that such is the final effect of progressive gigantism in animal species and in organizations: The economy of scale, positive at the beginning of the process, turns a liability when the problems of internal communication and the cost they cause do finally become overburdening.

0798

CYCLE (Equilibril) ²⁾

According to St. BEER, in an equilibril cycle: "... there are, as it were, a number of competing equilibria, and a stimulus greater than that confluent's threshold can contain will throw the representative point into one of several possible alternative confluents, depending upon the position of the point in the cycle at that time." (1968, p.477).

Equilibril cycles are proper to polystable systems, in which a number of different and alternating behaviors are admitted according to the nature and strength of the inputs received.

The set of alternative confluents (or in topological terminology, "basins of attraction") is however contained into a global vecinity. This means that the system, while adaptable to different environmental conditions, remains however organizationally closed.

0799

CYCLE (Functional) ²⁾ - 5)

J.von UEXKÜLL was one of the first to recognize the existence of functional cycles (1928, reed. 1979), which became later on one of the most significant cybernetic models.

He recognized them as "indivisible wholes" (p.295) and established even a diagram of the regulation device, in which he recognized: 1) the reciprocal and cyclical action of the observer and the object.

2) the main parts of the cycle: the object, the perceptions device, the internal universe of the observer, with its comparing devices, the activating connections and the effector (p.158).

He used this diagram as a model to be applied to biological behavior and ethology, but its very general character is obvious.

0800

CYCLE, in a network ²⁾

"The updating loop in a synchronous interactive network" (W. BECHTEL & A. ABRAHAMSEN, 1991, p.305)

The authors add: "One presentation of an input pattern results in multiple cycles of processing during which the activations dynamically interact until the network relaxes in a stable state (a state in which the input to any unit does not change the probability of activation of the unit) (p.305)

The general behavior of the network is thus quite similar to ASHBY's homeostat's behavior.

The authors also observe that "Cycles, which involve computation of activations, should not be confused with training epochs, which involve computation of weights" (p.306). In this last case, the strength of the connection between two units (also called nodes) is modified.

0801

CYCLE (Inclusion) ²⁾

A higher level cycle, superposed on lesser levels ones, that acts as a general process regulator (see fig.)

This model has been introduced by K. STEINBUCH (1974, p. 112). It gives a quite clear understanding of J.van GIGCH's control by recursion.

This very general model can be observed in many behavioral situations.

see figure below

Figure: see entry Cycle (Inclusion)

0802

CYCLE (Internal) ¹⁾ - 2) - 5)

Elaboration and self-consumption of products within a system.

Many complex systems elaborate products for their own internal use.

H. ODUM gives the example of the photosynthetic production, which is generally measured as a flow between producers and consumers. However, as stated by ODUM: "The actual gross photosynthetic process is much greater than can be measured in this way, because there is fast internal cycling (making and using) in the day stimulated by photorespiration and by the impetus of storages in the various sites of reaction in the cells of the plants" (1971. p.50).

The same kind of erroneous evaluation results of the computing in strict terms of monetarised exchange the gross product of archaic peasants communities: what they produce for their own use is not taken in account.

0803

CYCLE (Life) ¹⁾ - 2)

K. BOULDING states: "It is evident from the study of organizations of all kinds that they exhibit periods of growth, of relative stability and of decay" (1952, p.39).

This characteristic seems to be very general and affects practically any complex system, be it physical, biological, ecological, economic or social. Its deepest causes are still quite obscure, but are probably related to the 2nd Prin-

THE INCLUSION CYCLE

- The system is included in a specific environment
- The subsystem, or subsystems are included within the system, which is their environment
- Optimally, the environment recycles the outputs of the systems or subsystems and the input sources are replenished

ciple of thermodynamics. Since any system, to organize itself, must separate from its **environment**, it thus acquires a limited and precisely defined **level of organization**. This **level** is created by way of a basic **template**, also limited, and thus progressively reaching **saturation**, i.e. unable to maintain a sufficient **adaptability** (which should be carefully distinguished from the antinomic **adaptation**, which is a stabilized and limited collection of possible **states**).

A typology of life cycles **patterns** can be helpful in the study of **growth** and **decay processes**. The following can be distinguished:

- **normal**: Accelerating **growth** followed by decelerating **growth**, reaching a maximum and thereafter accelerating **decay** followed by slower **decay** until the end of the **process**.
- **linear**: regular arithmetic **growth**, theoretically – while not practically – unlimited in **time**.
- **exponential**: permanently accelerating **growth** (through some **positive feedback**, for instance), also theoretically unlimited in **time**.
- **asymptotic**: progressively decelerating when nearing maturity and tending to a defined upper **limit**.
- **logistic**: Accelerating **growth** followed by deceleration, but thereafter tending to asymptotic.
- **oscillating**: characterized by a series of **growth** and decrease, **periodic** or aperiodic **phases**.
- **embedded**: the cycle is limited by the **patterns** of a higher **level** cycle of longer **periodicity** and greater **amplitude**. Various **levels** of **embedment** are possible.

Numerous combinations of the forementioned **patterns** can be encountered, as for instance:

- **oscillations** may appear within a general **long term trend**, which itself can be of one or another basic type. An example are WADINGTON's **chreods**.
- innovative **spurts** may prolong the cycle, delaying final **decay** for some **time**.
- **decay** can be interrupted by **stabilization** at an intermediate **level** (plateau).

0804

CYCLE (Limit) ²⁾

A closed cycle characterized by the periodic repetition of given **trajectories** in a **dynamically stable** system.

Limit cycles were first described by H. POINCARÉ and are now known better known as **cyclical attractors**.

J. CRUTCHFIELD et al state that: "A limit cycle describes stable **oscillations**, such as the motion of a pendulum clock and the beating of a heart" (1989, p.42).

A stable limit cycle corresponds to a **domain of attraction** and, in topological **models**, to a **basin**.

A **trajectory** or system may leap out of its limit cycle (**switching**) under the impact of some strong **perturbation**. A recent example has been the destruction of comet SHUMAKER – LEVY 9, whose orbit was heavily perturbed by Jupiter.

→ **Limit cycle**

0805

CYCLE (Recurrent) ²⁾

According to W.R. ASHBY: "If a **line of behavior** is re-entrant to itself, the system undergoes a **recurrent cycle**" (1960, p.49).

However, if the cycle is submitted to a non-compensated **positive feedback**, an **instability threshold** will eventually be crossed and a **runaway process** will be triggered, leading in most cases to the destruction of the system.

0806

CYCLE (Stable) ²⁾

After defining what is a **recurrent cycle**, ASHBY states that: "If the cycle is wholly contained in a given **region**, and the **lines of behavior** lead into the cycle, the cycle is stable".

ASHBY gives an enlightening example: "Such a cycle is commonly shown by thermostats which, after correcting any gross displacement, settle down to a steady **oscillation**. In such case the **field** will show, not **convergence** to a point but **convergence** to a cycle" (1960, p.49).

0807

CYCLE (Stable limit) ²⁾

"A persistent **pattern** of **endogenously** driven cyclical **behavior** of a system" (T.F.H. ALLEN & T.B. STARR 1982, p.278).

0808

CYCLE TIME (Endogenous) ²⁾

"The **time** taken for a system to complete a **cycle** of characteristic **behavior**" (T.F.H. ALLEN & T.B. STARR, 1982, p.267)

ALLEN and STARR give as an example a single heartbeat and they comment: "The **endogenous** cycle time determines the **time** taken for a **holon** to return to its **equilibrium behavior** after being influenced by an external **signal**. This is sometimes called the **relaxation time**, an alternative **criterion** for arranging **holons** in **hierarchies**" (p.37).

0809

CYCLES (Pseudo-) ²⁾

K. BOULDING observed that the mechanical use of **spectral analysis** is: "...an elegant way of detecting probably nonexistent cycles and

throws no light on the real **structures** and **processes** which underlie **fluctuations**" (1972, p.86).

In other words, the results of **spectral analysis** of curves must be validated. The subject is quite difficult in the study of the **behavior** of **nonlinear** systems, when various periodic **functions** of different **periods** and **amplitudes** do reciprocally interfere.

0810

CYCLIC ORDER ²⁾

The periodic reappearance of some sequence of **activity** in some behavioral **pattern**.

The classical example are the periodic fluctuations in the Belousov-Zhabotinskii **reaction**. (A. WINFREE, 1980).

This type of repetitive **patterns** is however very general in **self-organizing structures**. B.F. MADORE and W.L. FREEDMAN demonstrate as much by computer **simulations** (1987, p.252).

According to them: "All that is required for our simulated chemistry experiment is a mix of "**elements**" which react in such a way that they will be found sequentially in one of three main **states** (active, receptive and quiescent); that these **states** occur in a cyclic order; and that there are a few simple **rules** as to how one **state** leads to the next".

And "... the first basic **forms** found in these experiments - the rotating **spirals** and expanding closed **circles** - are **topologically** related. Once the **circles** are explained the **spirals** are, in fact, a natural (expected) consequence" (p.254).

"Interestingly, the computer **model** does not involve any chemistry per se; it works with only a set of "**allowed states**" and a set of **rules** for the **interaction** and **transition** between **states**" (p.255-6). It is fact a **cellular automaton**.

The subject is closely related to J. CONWAY's **Game of Life**, to I. PRIGOGINE's models of the **emergence of order** through **bifurcation** and **nucleation**; to Ch. LAVILLE's **vortexes** and to D. Mc NEIL's **toroids**.

0811

CYCLICAL or PERIODIC ? ¹⁾

K.DE GREENE warns: "... confusion can arise from regarding "cyclical" as synonymous with "periodic" (1988, p.283).

Periodicity supposes a clearly defined **frequency**, normally combined with an also well defined **amplitude**. Periodic curves are sine **waves**, ideally perfect ones. But perfect **periodicity** supposes the also perfect **stability** of **environmental** conditions, whether in astronomy or in economy.

Such a **situation** is merely an abstract scheme, which explains the general failure of purely formal **forecasting**.

In real **situations** we witness numerous combinations between cycles of very different **frequencies** and **amplitudes**.

Some cases are more or less manageable, when one of the superposed cycles is strongly dominant. These **situations** have precisely been those which gave rise to the general idea of cycle. **Populations ecology**, for example, offers such cases

However, this is exceptional. The normal case is the superposition of various, or even numerous cycles of different **frequencies** and **amplitudes**, some of these quite comparable, others covering widely different **time spans**.

The composition of such a **variety** of characteristics yields normally curves that seem completely irregular, with **unpredictable** and sudden **changes** of orientations. (so-called **chaos situations**) A very good example is given by the stock market vagaries.

There are however some intermediate **situations** which look more promising:

1. When the respective **frequencies** are commensurable, even in the case when one **period** is so very much longer than the other or others that it may escape **observation** and analysis.
2. When the respective **frequencies** are incommensurable, but covering not excessive **spans** of **time** as to be still practically observable. In such cases, the complete cycle corresponds to the least common multiple of the **frequencies**. For example, a complex cycle of 1547 years would be the result of three interfering cycles of 7, 13 and 17 years.

However, the practical problem is quite intractable, because the detection of any regularities demands to begin with, a large series of **observations** of a generally confuse type of **situations**, covering a very long **span** of **time**.

Nevertheless, the concepts of periods **embedment**, of **renormalization**, of **fractalization** and of **deterministic chaos** may be of some help in the future.

→ **Self-similarity** in the **WEIERSTRASS** function.

0812

CYCLICITY

→ **Organization: a descriptive language**

0813

CYCLING RECEPTOR (or module)²⁾

A section of an **energy network** where an **input** of **energy** is used to motor an on and off **action** and then passed along downstreams in the **network**.

H. ODUM who introduces this **model** writes: "In this module **energy** interacts with some cycling material producing an **energy-activated state**, which then returns to its desactivated **state**, passing **energy** on to the next step in a

chain of **processes**. The kinetics of this module was first discovered in a reaction of an enzyme with its **substrate** and is called a MICHAELIS – MENTON reaction" (1971, p.39).

0814

CYCLOGENESIS^{1) – 2)}

Self-organization of the various functional **rhythms** in a system during the **process** of its **morphogenesis**.

0815

CYCLOMORPHIC^{1) – 2)}

Character of a **process** that seems to show irregular or imperfect **cyclical behavior**.

This corresponds to the practical situation in **concrete systems**, whose **periodic behavior** is submitted to numerous **endogenous** and/or **exogenous perturbations**. Interferences between **cycles** of different nature within a **complex system** may also lead to a global cyclo-morphic character, closely similar to **chaos**. Some of these – but not all – may themselves be **cyclical** or cyclomorphic. This explains why **cyclical models**, even **cross-level embedded** complex ones, are practically never entirely satisfying. It does not however mean that they are useless: fuzzy **predictability** is better than total **unpredictability**.

D

0816

DAMPING²⁾

A check on **fluctuations** in a system.

Damping is generally the result of **regulation** by a **negative feedback** which impedes excessive **fluctuations**.

When giant **fluctuations** set in, the damping capability of the system is strongly reduced, **instability** surges, a **bifurcation** (or **catastrophe**) may occur and **chaos** may eventually set in, or a system of higher **complexity** may emerge.

Damping may also result from a limiting influence exerted by **environmental** conditions through the **boundary** of the system.

K.De GREENE observes: "Damping increases with increase in surface/volume ratio or **interface zone** and stems from **interactions** on the **boundaries** of the **fluctuation region**" (1988, p.291).

0817

DATA^{3) – 5)}

Any **elements** of **information**.

G. BATESON observes: "... "data" are not **events** or **objects** but always records or **descriptions** or **memories** of **events** or **objects**.

Always there is a **transformation** or recoding of the raw **event** which intervenes between the scientist and his **object**" (1973, p.24).

This is true not only for the scientist, but also for any human being. Moreover, the **transformation** is at least physical and physiological and, as stated again by BATESON: "... always and inevitably, there is a **selection** of data because the total **universe**, past and present, is not subject to **observation** from any given **observer's** position... (and) no data are truly **raw**, and every record has been somehow subjected to editing and **transformation** either by man or by his instruments" (Ibid).

It could be added that data make sense only in **contexts**, acquiring different shades of **meaning** in different **reference frames**.

From another angle, the meaning of the word has been subtly changed since the advent of computers. In computers, data are not only collected, but also organized in order to be retrievable according to need for **information** treatment. As observed by W. REEVES: "Data is the specially designated electronic machine version of **information**. It has some **structure**, it may be true or not. It is not a **process**, but it does have the potential to render a **meaning** in the human **observer**. It lacks the human to human **connection**, but what is stored as data can only exist from human intervention either as **input** or **algorithm**" (1992, p.1100).

0818

DATA ANALYSIS²⁾

T. BAUMGARTNER et al. state: "A major task of data analysis is to assist in the **choice** between alternative **models**. The question arises then, under what conditions would the analysis of empirical data suggest a **multilevel** system" (1976, p.36).

Besides, different possible uses of the data may imply a **choice** between different **models** to organize them. A very general problem arises from the frequent necessity to use short or very short series of data to integrate a would be **long-term model**, in order to obtain some **forecasting** power. As shown by the Italian demographers C. GINI (1952, p.81-92) and C. CIPOLLA (1973, p.63-70), imprudent **extrapolation** can lead to quite absurd **forecasts**: A seemingly **exponential growth** at **short term** may very well be a **logistic growth** (or asymptotic, or other) when, later on, some **control** factors become more effective and visible.

We now moreover know that some **processes** are **chaotic**, which adds a new type of difficulty to select a really **fitting model** for data **integration**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0819

DATA (Analysis of time-series)²⁾

K.De GREENE states that there are many difficulties associated with analysis of time-series data related to **complex systems**, as "... for example, the absence of spottiness of data, appropriate data in particular and the **aggregate nature of data**" (1988, p.288).

Moreover, when applied to complex **cycles** research: "Methods of averaging and filtering, including the **selection** of moving averages to eliminate the masking higher-**frequency fluctuations**, tend to be subjective and may produce distorted results... two kinds of errors can occur: missing the existence of a **cycle** or **wave** when it really exist, and reporting a **cycle** or **wave** when none exist (the so-called SLUTSKY effect)" (ibid).

These are the problems of practical use of **FOURIER (harmonic) analysis**. In a different form they also appear in the **design** of systems in FORRESTER's **systems dynamics**.

0820

DATA REDUCTION²⁾

"A **process** of data summary achieved by any of a large number of methods of multivariate analysis" (T.F.H. ALLEN & T.B. STARR, 1982, p.265).

ALLEN & STARR remark: "After reduction, a large and complex data set may be represented approximately through expressing **interrelationships** between **observations** either by placement on a small number of axes or by grouping them together in a series of discrete **classes**" (ibid).

Of course, the **selection** of the reduction **model** is subservient to the **objectives** of the modelizer.

0821

DECAY^{1) - 4)}

The progressive degradation, disorganization of a system.

Decay is generally due to a non-compensated **negative feedback**, which progressively dampens the **resilience** of the system, i.e. its capacity to adaptively fluctuate within a not too narrow band of **values** or **situations**.

It also can result of the depletion of critical **elements** in the system.

Decay is somehow associated with **ageing** in **living systems** and also with clogging by excessive **accumulation** of some **types of elements** or residues, which poisons the system.

It is also related to the progressive loss of **redundancy**, and **saturation** of **information channels** in **social systems**.

In interactive **parallel processing networks**, decay refers to a decrease of **activity** in the **network**, i.e. a decrease of the number of **activation events** in function of **time**.

0822

DECIDER^{2) - 4)}

"The executive **subsystem** which receives **information inputs** from all other **subsystems** and transmits to them **information outputs** for **guidance**, **coordination** and **control** of the system" (J. MILLER, 1978, p.3).

The decider is one of the **20 critical subsystems** in J. MILLER's **taxonomy of living systems**. In **complex systems**, there are generally deciders at every **level**, responsible for their own **level** and sublevels

0823

DECISION^{1) - 4)}

"Logical **operation** enabling an **autonomous system** to act in order to reach some **goal**" (M. BELIS, 1987, p.57).

According to J.Z. YOUNG, decision is "the **process** of choosing between alternative **programs of action**" (1974, p.291). It implies the introduction of new **constraints** in order to limit **choices** and clearly define the chosen alternative. Of course, alternatives should be clear and, as decision is generally related to the **management** of systems, which require global **understanding** of complex **situations**, the **systems approach** is a basic tool

M. BELIS comments her definition: "This is proper to **cybernetic systems**, which are finalized **autonomous systems**" (ibid).

Capacity of decision is an aspect of **autonomy** in P. VENDRYES sense, i.e. the ability of a system to **regulate** and **control** its internal **states** (1989, p.147).

Some systemists speak of a "decision science" which should explore the conditions of **decision making**. Considering the multiple historical and cultural differences, as well as the widely different **situations** that condition **decision making**, constructing such a science would be a considerable challenge.

0824

DECISION CONTEXT¹⁾

The **set** of the internal or external **constraints** bearing on the system or **situation** object of the decision making **process**.

As stated by M. TODA: "... the more stringent the total **constraints**, the narrower the sphere of possible plans" (1976, p.83).

As in any evolving **situation** the decision context may vary, its permanent **observation** is required in order to update the decisions when necessary.

0825

DECISION HIERARCHY²⁾

An **embedded set** of decision **processes** of wider and wider scope from lower to higher **levels**.

M. TODA states: "(a) given decision problem may be a **nested** one within a grander decision problem which is **nested** within a further grander decision problem and so on. Formally, therefore any decision problem is situated within an infinitely **self-embedded** hierarchy of decision problems, which shall be referred to as the decision hierarchy" (1976, p.80).

It is however difficult to see why the decision hierarchy should be infinite. ("The buck stops here"!)

0826

DECISION MAKING^{1) - 4)}

"A thinking **process** which pervades all problem-solving **activities**" (J.van GIGCH, 1978, p.81).

"**Iterative** thinking at the basis of **Systems Design Process** by which plans are made and alternatives chosen for implementation" (J.van GIGCH, 1978, p.589).

van GIGCH states: "Decision making is a term sometimes reserved for the **action** of making a **choice** among alternatives. This is a narrow interpretation of the **concept**" (p.81). van GIGCH broadens considerably the scope of decision making and shows that a good **knowledge of context** and **context of context** is an important factor for reaching sound decisions. His very developed arguments unfortunately cannot be satisfactorily resumed here (see chapter 4 of his book).

E.J. KROWITZ, in accordance with H. SIMON principles of decision making, states the necessity to cling to "**choice of bounded rationality**", which implies "a decision **process** by which policies are selected that may not be optimal but are not inconsistent with important system **constraints**" (1991, p.48).

However, as observed by K.DE GREENE: "In decision making **situations** an unwarranted degree of **rationality** and **optimality** are often assumed" (1990, p.51). Uncertainties, for example, can be formally acknowledged, but their real scope actually ignored. And the use of terms like "satisfactory, adequate, useful" and the like frequently occult subjective and/or self-interested valuations.

On the other hand, **models** used in decision-making are generally based on implicit **assumptions** and biases about the nature and the actual **dynamics** of the system (for instance, trying to merely re-establish **stability** in **situations** of irreversible **change**), not to speak of the possible deformations resulting of the formalization **process** itself.

Moreover, one of the main problems of the decision maker is to discover *all* the important **constraints**, many of which, as observed by J.van GIGCH, originate in the **metasystem**.

A very serious problem affecting decision-making is denounced by M. DODDS: "... human **values** are relegated to an inferior status and a **variable** to be discounted in rational **planning**

and decision-making, the rational concern being with feasibility, with "given **means**" and with their **optimisation** in every **context**. Operationalized as "development policy", we have seen how it failed in the Third World", and in the guise of "shock therapy", we see the effects in the former Soviet Union and Eastern Europe where the entire cultural **configuration** of a society is not taken in account" (1994, p.1419). Obviously, the **problem** behind this **problem** is the lack of a practical **method** to generated a wide, satisfactory and sufficiently fast **consensus** of all **stakeholders** in critical **situations**. This is a **double-bind** case: Some really sound **changes** are impossible without democratic **consensus**... but cannot be postponed until all **stakeholders** can acquire the necessary **knowledge**, **understanding** and sense of personal responsibility.

M. DODDS herself recognizes this, at least implicitly: "The separation of authority and responsibility, and the separate **optimization** of societal **functions** creates structural **conflict** between different **functions** as well as between government and civil society" (Ibid). Still, where is the short cut we need: *Enlightened co-participative design* is possible within limited groups, but how to generalize it for thousand or millions of participants (generally anxious for swift **change**, ill-informed about real possibilities and frequently manipulated by groups of "hidden persuaders")?

I.I. MITROFF and H.A. LINSTONE, using their **Multiple Perspective Concept**, observe that the "Organizational or Societal Perspective" is much better understood in China: "Chinese culture is bureaucratic and hierarchical so that Organizational **games** and **strategies** are generally known to everyone.... (However), Personal perspectives present more of a hurdle" (1993, p.107).

0827

DECISION- MAKING STRATEGIES ⁴⁾

Most of decision-making strategies are more or less **reductionist**. As noted by T.R. BURNS and L.D. MEEKER: "This strategy eliminates problems of having to **process** and deal with different **evaluations**, at least in most phases of decision- making. Above all, it enables **conflicts** between different **goals** or evaluative standards in concrete settings to be articulated in relatable terms and resolved within an unidimensional **value** framework... Internal **complexity** of the decision-making system is reduced in order to achieve greater or easier computability and decidability, but this may be at the expense of essential representability of external **complexity** and effective **action** in a complex **environment**" (1976, p.112-3).

This could be good enough in simple **situations**.

However, **situations** may not be as simple as they seem... and the decision-maker may not be aware of it.

In order to allow for more secure **evaluations** prior to **action**, a systemic strategy should carefully consider the relations of the system with its **metasystem** (van GIGCH), in order to discover if some of these have some significant – and possibly ignored – bearings on the system's **behavior**.

It should also consider its internal **organization**, in terms of **network relationships** and **organizational closure**, since some unknown **self-referrent behavioral cycle** may react to some decisions by possibly uncontrollable blockages or **runaway processes**.

Still another, and quite subtle problem is the possible **incompatibility** between **multiple objectives**, which could be partial or total, or a result of an erroneous **understanding** of the relations between different **time scales**.

This should be addressed by a better systemic **understanding** of the potential **availability** of **resources**, the need for **regulations** and the possible differential **cyclical behavior** of some **variables**.

In very complex systems, decision-making should ideally be a final result of wide participation of all the **stakeholders**.

→ **Design (Co-participative); Design (Generic)**

0828

DECISION PROCESS ^{1) - 4)}

The sequence "of all the **subprocesses** pertaining to the **selection** of a course of **action**, or a plan, and its execution" (M. TODA, 1976, p.79).

TODA observes: "Most of these **subprocesses** except some well formalized ones like decision analysis, are covert processes taking place exclusively in somebody's mind, and are hitherto paid relatively little attention" (Ibid).

Taking a decision is the **end** of a frequently long and complex process.

It also is, in many cases, an **embedded part** of a more global ongoing one.

As to the first aspect, the **decider** needs **information** about the **situation** which requires the decision. This implies an **inquiry**, generally in order to obtain a better evaluation of an **ill-structured problem**. The results of such an **inquiry** mostly depends on the acumen of the decision-maker (or his/her assistants) in selecting the relevant **data** within the relevant **frame** and in converting them into the adequate **information**.

An important aspect of this search process is a correct **evaluation** of the more general conditioning factors, i.e. the evaluation of the **model** of the **situation** within a **meta-model** in which seemingly irrelevant factors may suddenly emerge as fundamental.

A good definition of the **goals** may also be difficult, because they can be **fuzzy**, or complex and in need to be compatibilized or serialized.

Once the **goal** is defined, it generally can be reached only through an **ordered sequence** of decisions, each one at its proper **time**.

Finally, no process escapes from possible unforeseen **disturbances** in the **environment**. It must thus be reconsidered frequently and this may lead to **changes** in the **evaluation** of the **situation** and in the **sequence** of decisions.

Decision process with or without disadvantage compensation

M. MARUYAMA observes that most decision processes leave dissenting or damaged minorities "in the cold". He writes: "It is commonly considered "democratic" to make decisions by voting, in which a majority wins. The majority preference is justified and legalized, and minorities are put at a disadvantage and forgotten. This false concept of democracy is the cause of the current trend of division of countries into smaller countries" (1994, p.40).

This very general cause of strife, sabotage, secession and **conflict** is also verified in many lesser **organizations**: enterprises, political parties, churches, civic **groups**, etc.

MARUYAMA gives examples of disadvantage compensations and shows how they could be provided, in order to maintain internal harmony in **human systems**.

0829

DECISION PROCESS (Delayed) ^{1) - 4)}

A process in a complex system by which decisions are taken only after extensive recirculation of the available **information**.

In such processes the **feedback** of the available **information** among the **elements** or members of the system allows **time** for the progressive **ultrastabilization** of the system, centering the decisions to be taken towards the **optimum**.

Such a process can be modeled by **attractors**.

This cooperative **behavior** seems to be a characteristic of widely different types of systems, as for example:

- The search for the location of a new beehive by swarming bees (T. SEELEY, 1989).
- The cooperative **learning** process by neurons in the **brain** (L. PERSONNAZ et al., 1988).
- The **recursive method** for decision making in Japanese firms.

0830

DECISION SCOPE ^{2) - 4)}

The all-embracing area that must be covered by the **decision process**.

M. TODA describes it as follows: "The background **field** upon which the **decision tree** lies, defined jointly by the preselected plans, the horizon and the **structure** of the tree **network** produced by the **hierarchical organization** of the decision will be called the decision scope" (1976, p.81).

0831

DECISION THEORY ^{1) - 3)}

"The corpus of theoretical **knowledge** which bears on the **process** of reaching the best decision" (after S. BEER, 1968, p.211).

This corpus is now enormous and quite dismembered, since it has been considered from numerous and varied viewpoints by many authors. However, BEER's cybernetic and systemic 1968 treaty on "Decision and Control" remains a most important source on the cybernetic-systemic decision theory.

According to M. BELIS: "The decision theory aims at the establishment of a rational base for **action** in **uncertainty**. It is a normative theory as it elaborates the **rules** along which a rational **decision making** system (human or technical) should operate in order to reach its **goal**. It is also a descriptive theory which tries to discover and formalize those **algorithms** used by human beings when facing **uncertainty**."

"When facing a decision problem, the system must choose a **response** (or an **action**) in order to maximize a **performance** index. The interference of the **response** with the **environment** generates an **event**, namely the result, whose usefulness is assessed by comparing it with the **goal**."

"The **uncertainties** that may exist in a decision problem are related to the **state** of the **environment**, to the **set** of possible **actions**, to the potential results and their usefulness in relation to the **goal**. The decision system may be short of **information** on one or various of these points. Sometimes **uncertainty** may affect the **goal** itself."

"One of the fundamental, and still not solved, aspects of the decision theory is related to the **algorithm** which should allow us to transform the incomplete and disparate **information** at our disposal in relation to the **states** of the **environment**."

"This leads to question the very fundamentals of the **concept** of probability, which should from now on acquire a broader **meaning**."

"It must be also defined in the cases of isolated (non recurrent) **events** and permit to calculate the numerical value of the apriori probability (i.e. before the experiment) in the general case of unequally possible **events**" (1987, p.57-58).

Decision theory is also concerned with **risk assessment**, **cost** and benefits **evaluation** and programming of the best course to follow in **time** in relation to **resources** presently available or supposed to become available in due time.

0832

DECISION TREE ^{2) - 4)}

The ordered sequence of the decisions taken or to be taken.

"A decision tree is essentially a branched list of questions in which the answer to one question determines the next question asked"

The decision tree is generally represented by a branching **graph**.

Each question is called a "**node**" on the tree, and each answer leads to a separate "**branch**". At the end of each branch lies a "**leaf node**", where the decision tree assigns a **classification** to the **data**" (C.E. BRODLEY et al, 1999, p.57).

Of course, each **node** represents a hypothesis with different conjectures, formulated in accordance with some **assumption** about the **process** under study.

M. TODA describes the decision tree as follows: "Several alternatives courses of **action**, which I shall call plans..., are neatly organized into the form of a decision tree. All the alternative plans branch out from the **node** representing the current decision **situation**. Then each of the plans-branches fans out at a **chance node** over which is assigned a probability **distribution**. Then, at the end of each finger of the fan one will find another subdecision **node** from which subplans branch out further. After repeating these branchings several times, each route will end up at a certain **terminal state**. Utilities are assigned to various locations all over the tree, and also to all the terminal **states**."

"Given the fully worked out decision tree, it is a simple matter of computation to determine which plan produces the highest expected utility, and the end of computation is followed immediately by the moment of deciding" (1976, p.79).

Such a neat – and quite formal – ordering does not however insure in itself the good **fit** of the plan: it merely defines the correct **sequence** to be followed, once a general – and supposedly satisfactory – decision has been taken about the global plan.

0833

DECISIONS (Collective) ⁴⁾

The global results of very numerous individual decisions taken simultaneously.

Of course, the global **effects** observed are nobody's personal responsibility. But, as observed by W. HARMAN, we should seek a way "toward resolution of the fundamental dilemma that the resultant of the microdecisions is so typically an unsatisfactory macrodecision" (1972, p.91). As noted by HARMAN the solution should not depend on Adam SMITH "invisible hand", nor on manipulation by a technocratic elite or by irresponsible bureaucracies. Rather, in HARMAN's words "it depends on re-education to perceive suitable macrodecisions and appropriate microdecisions to lead toward them, and on a shift in cultural values to support the process" (Ibid).

tion to perceive suitable macrodecisions and appropriate microdecisions to lead toward them, and on a shift in cultural values to support the process" (Ibid).

The issue of global pollution, and the global decisions to be taken and applied, in all their **complexity**, is a very good example, among many others.

0834

DECODER ²⁾

"The **subsystem** which alters the **code** of **information input** to it through the **input transducer** or internal **transducer** into a "private" **code** that can be used internally by the system" (J. MILLER, 1978, p.3).

The decoder is one of the **20 critical subsystems** in J. MILLER's **taxonomy of living systems**.

0835

DECODING ²⁾

The **process** of restoring original **messages** from the forms in which they were transmitted, stored or enciphered, by applying a suitable **code**" (K. KRIPPENDORFF, 1986, p.22).

Of course, the **decoder** must know the sender's **code**. Decoding implies two **levels**: 1) the physical coherent restoration of the original **signals** (as in phones of TV sets) and, 2) the correct interpretation of the **symbolic** or **semantic meaning** of the **message**. In all cases, the **code** must be **shared**, even if the final result is a derived interpretation (as for instance in false colors **maps**).

Satisfactory decoding depends at least on the following three conditions:

- The existence of a limited amount of **noise** in the physical **channel**, as to maintain distortions to a minimum at the **receivers** end;
- the physical and physiological capacity of the receiver to pick up the **message**;
- the **knowledge** by the **receiver** of the sender's **semantic** and **syntactic code**.

0836

DECOMPOSABILITY ^{2) - 3)}

Decomposability gives itself in various degrees, corresponding to various **levels**. This has been stated by H. SIMON in the following way: "... **hierarchies** have the property of near-decomposability. Intra-component **linkages** are generally stronger than intercomponent **linkages**. This fact has the effect of separating the high-frequency **dynamics** of a **hierarchy** – involving the internal **structure** of the **components** – from the low frequency **dynamics** – involving **interaction** among **components**" (1965, p.72).

0837

DECOMPOSABLE (Nearly) SYSTEMS²⁾

According to H. SIMON: "At least some kinds of **hierarchic systems** can be approximated successfully as nearly decomposable systems. The main theoretical findings from the approach can be summed up in two propositions:

"a) in a nearly decomposable system, the short run **behavior** of each of the **component subsystems** is approximately independent of the short-run **behavior** of the other **components**.

b) in the long run, the **behavior** of any one of the **components** depends in only an **aggregate** way on the **behavior** of the other **components**" (1965, p.69).

This implies that **complex systems** are, by their nature, **heterogeneous**, i.e. made of different types of **parts**, that can act with some degree of **autonomy**.

However, it means altogether that every **subsystem**, on its own, is strongly coherent, as well as the **complex system** taken as a **whole**.

No **complex system** could survive any of the two following conditions:

a) complete **homogeneization** of its **parts** or **subsystems**

b) total **independence** of the same.

Moreover, the **behavior** of the **parts** may fluctuate in a more or less **random** way, but within the **limits** of local and global **determinisms**.

This is still more so in the case of imperfectly **integrated systems (composite systems)** as for example a **population**.

0838

DECOMPOSITION²⁾

The construction of a **model** of a system in such a way as to conspicuously show its **subsystems** and/or **elements**.

M. TODA and E. SHUFORD state: "For a decomposition to be meaningful, there must be some means to obtain **information** about the **state** of each **subsystem** generated by the decomposition" (1965, p.8).

According to J.van GIGCH, decomposition allows "the decentralization of authority and of tasks" (1978, p.589).

There is a **reductionist** way and a systemic one to build a decomposed **model** of a system.

The first one is mainly interested in the **elements** themselves, because they are supposed to conceal the fundamental nature of the system. A good example is the quest for the basic, ultimate elementary particles in micro-physics.

The systemic decomposition seeks to understand the significant **interrelations** among the **structural-functional parts** of the system, i.e. the **critical subsystems** (In J.G. MILLER's sense).

Both types of decompositions are interesting and useful in their own way. In many cases, they could – and should – be used in a complementary way.

0839

DECONSTRUCTION³⁾

In the epistemological critique of science, an attempt to explore the psychological and sociological roots of the ways scientific **theories** and **models** are established ("constructed").

One of the first steps in this investigation has been Th. KUHN's work on the "Structure of Scientific Revolutions".

From a cybernetic-systemic viewpoint, H.von FOERSTER's comments about "**objectivity**" as "...a **subject's** delusion that observing can be done without him" (1983), led him to his Cybernetics of "**Observing systems**", no doubt, a voluntary **ambiguity** in terms.

von FOERSTER has been moreover an inspirator of H. MATURANA's **autopoiesis** and **organizational closure**, applied to the ways our **brains** construct their own structural **frames** and become somehow limited by their **organizational closure** as to what they are able to observe and the ways they observe it.

It should be however noted that cross-examination by various of von Foerster's "**subjects**" - if not resulting in collective delusion as it occurs sometimes - offers a base for what is generally called "**objectivity**" through compared **observations**.

Anyhow, in C. EMMECHE's words: "**Theories** are never pure copies but always help to constitute the "**objects**" that they connect into a rational **whole**. **Theories** utilize **models** of every kind as **tools**, and these **models** are projected onto the **object's domain** in order to compare the **model's behavior** with that of "**reality**". This applies regardless of whether we are speaking of purely verbal, informal **models**, physical **models**, or formal **models** that can eventually be simulated" (1994, p.162).

It is noteworthy to see EMMECHE put "**reality**" within quotation marks.

This way to question the "reality of reality" is in fact only a way to question our effective capacity to know **reality** - without quotation marks - "as it is", with quotation marks!.

This led however to a very strong reaction from physicists, as A. SOKAL and J. BRICMONT, who cannot admit that any description of reality is as valuable as any other, and can be left to the whims of self-appointed philosophers of science (1997). They seem to be at least partly right on both points: it is obvious - even pragmatically - that NEWTON's physics operativity speaks well for its value as a **representation of reality**, whatever this intrinsically means.

...However, EINSTEIN - two centuries later - proposed a wider **representation**, which did not disprove Newtonian mechanics, but proved still more operative in embracing a wider section of **reality**. In both case, these **representations** had to be finally admitted by **consensus** (i.e. in some cases a very deep **paradigmatic change** at the psycho-social level of the scientific establishment - KUHN!).

Of course, it would be unreasonable to doubt that science obtains in its progress more and more efficient (better and better?!) **representations of reality**. But we can never be sure that its most recent word is the last and uncontradictable word (as noted by POPPER).

All this boils down to the constant necessity to maintain a critical view, not so much about **reality** as of ourselves as "**observing systems**". After all, SOKAL and BRICMONT too are **observers**, construct **theories**, or adhere to **theories** constructed by their colleagues.

Very recently, a quite sharp turn can be observed in the ways scientific **models** and **theories** could be constructed.

Just as during the recent centuries the progress of scientific instruments became a motor of our changing view of **reality**, it seems that we are again on the edge of a wholly new way to create **models** and **theories**: by computer **simulation**.

EMMECHE, for instance, observes that we are entering the era of **bio-logics** through the construction of computer **models** of biological **behavior** (Ibid, p.163). A program is constructed with **rules** that are hypothesized to govern some specific biological **behavior** and the results of **simulation** induces us to confirm or discard our preconceived views: a fine way for observing "**observing systems**", as **observers**.

This could be considered a kind of incipient scientific **constructivism**.

→ **Derealization; Model building; Model making; Model validation; Ontological skepticism or agnosticism; Realism; Reality**

0840

DEDUCTION³⁾

A rigorously logical thought **process** that consist in reaching a conclusion in a specific **issue**, based on precisely stated general principles.

The classical example is: "Men are mortal. Socrates is a man. Thus, he is mortal".

The conditions of applicability of the deductive **method** should be however carefully scrutinised, because they imply:

- the "**et ceteris paribus**" principle: only really similar issues can be correctly treated in a deductive way

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

- the admission in each case of the validity of the general **determinism** implicit in the applied principles

→ **Abduction; Induction; Inference**

0841

DEFINITION ³⁾

A statement aiming at establishing the precise **meaning** of a term or expression.

The problem of definition is central to **systemic** and **cybernetic semantics**.

In J. WARFIELD's words: "... the definition of a term is in itself an **operation** of **integration**, but what is integrated varies from one approach to another" (1988, p.335).

WARFIELD establishes the following taxonomy of definitions:

"Definition by Naming. In this, the weakest form of definition, a **concept** is given a unique name and that is all that is overtly available to give it an **identity**.

"Second, one may consider Definition by Extension. In this **mode**, well established historically, one deals with a **class** name. The **class** is defined by presenting a **set** of names of exemplars of the **class**. This approach may often serve for initial introduction to a **concept**. It does not provide the depth of insight to allow one to answer such a critical question as to whether a **concept** X, not yet accepted as a member of the **class**, can or should belong to the **class**.

"Thirdly, one may consider Definition by intention. In this **mode**, one deals with a **concept** (which can be a **class**), and defines the **concept** by citing that **set** of attributes that is perceived to be integral to the **concept**. Oddly, this approach may involve both a division and an **integration**. The **integration** brings together a **set** of attributes thought to belong to the **concept**, while at the same time producing a division of the **concept** into the **set** of attributes, leaving open questions of completeness at times.

"A fourth type of definition is Definition by Relationship... but the extent of the **relationship** is a matter of considerable importance... **Definition by Relationship** is the highest grade of the four **modes** discussed" (p. 335-6).

Definition by Relationship implies the use of DE MORGAN's Theory of Relations, whose systemic and cybernetic character is obvious.

The basic **methodology** used in this dictionary is definition by **relationship**, taking in account that any **language** (current, specialized or formalized) tends to be **organizationally closed**.

0842

DEFINITION of a system (Basic)

→ **System (Basic definition of a)**

0843

DEGENERATION ¹⁾

"Process undergone by a system deprived of sufficient free **energy** and thus unable to maintain the integrity of its **rule** system" (Adapted from T.F.H. ALLEN & T.B. STARR, 1982, p.265).

ALLEN and STARR explain: "The system undergoes uncontrolled **change**, which results in a fundamental **change** in system **structure**, characteristic of underconnected systems" (Ibid). (This is because the scant available **energy** is not anymore sufficient to maintain all the **connections**).

0844

DEGREES OF FREEDOM ¹⁾

The measure of the leeway of **variability** in a system.

According to P. BERGE, Y. POMEAU and Ch. VIDAL, a degree of freedom may be understood in two different ways:

- either: "each couple of position-velocity coordinates associated with a possibility of displacement"
- or: "one only of these two elements: position or velocity"

"Thus a set of N bodies able to move in the three directions of **space** presents 3N or 6N degrees of freedom, according to the definition used" (1984, p.13).

The degrees of freedom define the dimensions of the **phase space**.

H. HAKEN and A. WUNDERLIN equate degrees of freedom with "**order parameters**". They state: "Indeed, three **order parameters** or degrees of freedom are enough to make the system **chaotic**" (1990, p.1250).

It is however to be noted that the degree of **correlation** in-between degrees of freedom is a very important factor: less correlated degrees of freedom induce **chaos** much more easily. (see; "**frozen core**") Or, in other terms, **incommensurability** is a determinant factor of **chaos**. The subject seems somehow related to **prime numbers**.

From another viewpoint, R. ROSEN states: "A **functional activity** manifested by any particular system typically involves only a few of the **structural** degrees of freedom of the system" (1974, p.63).

These "free" degrees of freedom are eventually available for other innovative **interactions** or **functional activities** of the system (see "**Function change**").

Degrees of freedom can also be understood in terms of **autonomy** (in P. VENDRYES' sense): Each internal **regulator** with counter-aleatory **reserves** at its disposal, enhances some degree of freedom of the system.

0845

DELAY ^{1) - 2)}

The **time** interval between two successive stages in a **process**.

Some steps in **processes** are more **time-consuming** than others. When **processes** are **interdependent**, the slower ones act as **timers** for the **whole complex system**.

This is, for example, the rationale at the basis of **planning**, and more specifically of **PERT**.

Ignoring differences between delays affecting interconnected **processes** may bring havoc into a system.

→ "**Time lag**".

0846

DELAY AMPLIFICATION ²⁾

The anormal lengthening of a complex **process** due to some small local **perturbation**.

The optimal **development** of a complex **process** is usually represented by a **critical path model**, where it can be observed that such a small local **perturbation** may diffuse in numerous subsequent branches of the **process**, leading to accumulative delay **effects**.

As explained by St. BEER, in such cases it is generally convenient to try to overhaul the whole of the **program** and try to compensate the initial **perturbation** through adequate **action** in order to avoid the development of an unmanageable **situation** (1968, p.192).

As a result, a new **critical path** is to be established.

The subject is obviously related to the **control of chaos** (E. OTT & M. SPANO, 1995).

0847

DELPHI METHOD ^{4) - 5)}

A process of consultation of experts about the future of a system or a relevant **variable** in a system.

This method – a kind of elaborated opinion poll – was introduced in 1963 by DALKEY and HELMER (RAND Corporation, 1963). It aims at establishing a qualitative and quantitative **evaluation** of possible future **changes**, as seen by a number of people (30 to 40) considered as experts at international level in the researched area. Experts remain anonymous.

This is done through written and standardized **inquiry** forms that must be completed according to a strictly defined method. While deviant opinions are admitted, general **convergence** is sought. The **process** is **iterative** and every expert is allowed to modify his/her opinions. After a number of **iterations** – generally four or five – a majority **consensus** is supposed to emerge, with quantitative **evaluations** (for example: there will be 55 % electric cars in 2020).

"The Delphi Method has been used in various **contexts**, in particular where no other procedure for obtaining answers to complex questions is readily available" (J.van GIGCH, 1978, p.432).

The method has been strongly criticized from different angles:

- Which are the **criteria** for selecting the experts?
- Answers are more or less dependent from the way the queries are put.
- **Consensus** is interesting, but gives no guarantee either that the odd man out's opinion is wrong, or that the **consensus** will hit the mark in due time... or ever!
- Conclusions are much more a result of more or less well or ill informed shared subjectivities than truly objective, as they are supposed to be.

M. TUROFF, among others, strongly criticized the method. His view is that it has been mainly used to justify pre-established opinions. DELPHI is obviously weak from an **epistemological** viewpoint. It seems to have been largely abandoned.

Delphi conferencing: A Delphi exercise conducted via computer terminals with "continuous operation and instantaneous compilation and **correlation** of the individual contributions to the group results" (after M. TUROFF as quoted by J.van GIGCH, 1978, p.435).

van GIGCH states: "The **method** of Delphi Conferencing serves to answer the question of designing a **method** that incorporates the advantages of the **Delphi Method** (controlled **feedback** and anonymity) and reduces some of its disadvantages (long **delays** between **iterations** and difficulty in accelerating the **interactions** of participants, without resorting to face-to-face confrontation" (p.435).

0848

DELTA RULE ²⁾

In **parallel processing networks**, "A **learning rule** that utilizes the discrepancy between the desired and actual **output** of each **output** unit to change the **weights** feeding into it" (W. BECHTEL & A. ABRAHAMSON, 1991, p. 306).

"It is also known as the WIDROW-HOFF rule and the least mean squares rule" (p.306).

This amounts to an adaptive **process** based on **feedbacks** and is the basic tool for the progressive betterment of the **efficiency** of the **learning network**.

→ **Learning (Back propagation)**

0849

DEMOSOPHIA ⁴⁾

"The wisdom of the people" (A. CHRISTAKIS, 1996, p.17). Christakis writes: "The name implies a **paradigm** shift from "the power of the people", which is the Greek meaning of the word democracy, to the "wisdom of the peo-

ple". The underlying premise of the new paradigm is that discovering the wisdom of the people is necessary if the people are expected to exercise their power. However, because of the escalating **complexity** of the contemporary societal **situation**, it is much more difficult today to uncover the wisdom of the people than it was two thousand and five hundred years ago during the golden era of the Athenian Republic" (Ibid)

Old Greek experience and present ones (for example in Switzerland the municipal participative debates open to all citizens) show that the "wisdom of the people" can be uncovered mainly (and possibly only) in reduced meetings of at most some few hundred citizens.

Moreover, the present complexity of human affairs at any **level** adds the need for sufficient **information** and evaluating **learning** for all **stakeholders**.

A special interest group of the International Society for the Systems Sciences, as well as the **Fuschl Group** have considered possible ways to revive *demosophia* in new style "agoras" of participative citizens, adapted to nowadays demographic, social and political conditions.

0850

DENDRITIC GROWTH ^{2/4)}

A way of growth through formation of **dissipative structures** along divergent **hexagonal branching fractals**.

A well known example is the **hexagonal growth** characteristic of snowflakes. But dendritic growth appears in many other systems, as for example trees, cities or **clusters** of human settlements (**hexagonal space filling**). It is the result of a very general way of dissipative **structuration** by which the already existing **structures** become definitory of the possibility of **accretion** of new **elements** during the growth **process**.

Dendritic growth **processes** have been mathematically modeled under the name of **diffusion-limited aggregation**.

0851

DENOTATION (Objective) and CONNOTATION ³⁾

According to E.von GLASERSFELD: "... one can show that even the commonest words retain a margin of subjective **meaning** for each individual speaker. Linguists and philosophers of **language** usually subsume this margin under the term "connotation", and they claim to be able to separate the subjective **component** neatly from "objective denotation". From our point of view, this claim rests on the illusion that words refer to things in the real world. In our theory ... words... refer to subjective experiences of the individual **language** user. The separation between denotation and connotation thus no lon-

ger involves **objectivity** but becomes a question of greater or lesser fit with the usage of other speakers.

"The result of our investigations in this area is that the **meanings** of words and longer segments of **language** are never "shared" with others in the sense that they could be considered the same for all members of a **language community**. All one can say is that among proficient speakers of a **language**, **meanings** are at best **compatible**, that is, they function similarly in most **situations**.

"This is an important difference from the artificial, technical **communication systems**. There, the **code** that bestows **significance** on the **signals** is established and distributed to the **communicators** before any **communication** takes place". (E.von GLASERSFELD, 1996, p.493-4)

The telephone repertory of numbers and subscribers could be a good example.

This is also related to the non-**semantic significance** of SHANNON's **Theory of communication**, as specified by SHANNON himself (and generally forgotten).

→ **Objectivity; Ontological Skepticism or Agnosticism**

0852

DENSITY (Critical) ^{1) - 2) - 4)}

The minimal number of individuals under which no collective or social **behavior** can appear, or alternatively the excessive density in a **socio-system** which triggers pathological collective **behavior**.

P.P. GRASSÉ observed that: "... on the occasion of the reconstruction of the nest by termites, there is a critical density of insects under which no **structure** can appear" (1959). He developed this **model** under the name of "**stigmergy**"

J.T. BONNER (1988) and J.A. SHAPIRO (1988) have documented a number of examples. Critical density is also a basic condition for the switch to **swarming** from solitary phase by migratory locusts as shown by UVAROV and FAURE in South Africa and the Belgian biologist H. BREDO in former Belgian Congo and in Central America (see J.P. HARROY: "La lutte anti-acridienne et Hans BREDO" (Académie Royale des Sciences d'Outremer, Bruxelles, 1985)

Critical densities **phenomena** also appear as a basic condition for the shaping and development of human settlements, as demonstrated by P. ALLEN (1982).

What is really critical seems to be the **crowding effect** when the **distance** between individuals is so reduced that a **threshold** is crossed where new **interactive effects** - whether constructive or destructive - become possible (see J. CALHOUN - 1962 and 1971).

Constructive **behavior** appear when numerous individuals coalesce into a system of higher **level**, and destructive **behavior** when **overcrowding** sets in.

The psychological aspect of the **effect** has been considered by E.H. HALL (1966), and the social ones where already more or less perceived by some sociologists since the end of 19th century (S. SIGHELE: The criminal crowd (1892); G.L.E BON: Psychology of the crowds (1895) and J. ORTEGA Y GASSET: The revolt of the masses (1929).

This very important characteristic of loose systems would deserve much more research.

The subject is also doubtless related to **criticality and percolation**, as for example in locusts **swarms** and lemmings collective self-destruction.

→ **Distance (Critical)**

0853

DENSITY OF OCCUPANCY ²⁾

Ideally, **space** tends to be occupied at the same density everywhere (See L.F. RICHARDSON – 1961, p.139).

However, many deforming factors must be considered.

Environmental conditions tend to vary in **space** as well as in **time**.

For example, when a new area is colonized by a **population**, the initial density is quite higher at the "bridgehead" than in the rest of the territory. With **time**, a progressive equalization should take place. However, this would happen only if the **environmental** conditions are more or less equivalent everywhere.

Differential densities of occupation can still be observed in many places in **ecosystems** or in countries like United States or Brazil, because of **environmental** differences both in **space** and **time**.

0854

DENSITY (Optimal) ²⁾

K. BOULDING enounces a principle which he calls "of equal **advantage**" which "...governs the **distribution** of the "substance" of a **structure** among the various **parts** of the **structure**" (1956, p.73).

The **advantage** obtained by a unit or **element** in a defined **location** "is an inverse **function** of the relative quantity of units in that **location** – that is, the fewer, the merrier" (Ibid).

In fact optimal density seems to depend on **two** complementary **parameters**:

1) Any **subsystem** or **structure** needs at least a minimum number of **elements** to become functional.

2) An excessive number of **elements**, i.e. **overcrowding**, produces a slowing down and, in extreme cases, a blocking of the **function**.

Moreover the density conditions vary according to the different stages of **growth** of the system. When **growth** starts, the relation of the system with an **environment** rich in **resources**, induces a considerable **multiplication** of **elements** and an increasing density of the **structure**. With **time** and as the system is nearing its optimal **dimensions**, this **situation** tends to reverse.

Excessive density is a condition favorable to **overburdening**, **overcrowding**, and **overload**. Examples are urban traffic congestion, or epidemics leading to **population collapses**. According to H. ODUM, "**diversity** and a check-and-balance system prevent epidemics and maintain **stability**" (1971, p.80).

0855

DENSITY (Reporting)

→ **Venn diagrams**

0856

DEPENDENCE ²⁾

"The **relation** in which the existence of one **part** is conditioned by some other **part**" (J. FEIBLEMAN & J. FRIEND, 1969, p.34).

"**Independence** is the absence of this condition".

Dependence implies a **hierarchic relation**. FEIBLEMAN and FRIEND give the following example: "...the limb of an animal is dependent upon the circulatory system, but not the circulatory system upon the limb" (Ibid).

They also state that grains of sand (randomly moved by the wind, let us say) are independent of each other. It should be observed however, that, in **composite systems**, like a sand dune, they are at least submitted to a kind of global statistical **order**. As stated by M. BUNGE: "Dependence may be probabilistic, whereas causation is deterministic" (1974, p.235).

F. VESTER emphasizes inner reciprocal dependence (i.e. **sybiosis**) in biological and social systems. He observes that short internal **distances**, reduction of exchanges with the **environment** through increased internal exchanges and lesser use of **energy** diminish dependence from the **environment**. (1983, p.82)

This confirms P. VENDRYES' concept of **autonomy**.

0857

DEPENDENCE AND INDEPENDENCE ^{1) - 2)}

P. VENDRYES writes: "In the 19th century, A. COURNOT (1801-1877) insisted more than anyone else on the fact that **randomness** appears when independent causal series confront each other. This remark leads to a general principle: **Relations** between two **objects** are **random** when they are independent of each other and **deterministic** when they are dependent.

"The fact that the pre-condition of **randomness** is independence, whilst that of **determinism** is dependence, vastly enhances the scientific value of the notions of dependence and independence. And because **autonomy** is an acquired independence it is rigorously logical to assert that physiology makes use of **randomness** in order to be intelligible and therefore is not reliant upon **deterministic** mathematics as its sole system of theoretical reference" (1989, p.146).

0858

DEPICTOR ²⁾

An internal device used by **autokinetic** animals to represent to themselves any variation of their **relations** with their **environment**.

This term was introduced in 1924 by A. LOTKA (p.339-40). LOTKA distinguished four **components** in depicitors: **Receptors**, elaborators, **adjustors** and **effectors**. Their interplay amounts to a global **correlation device**. LOTKA constructed a mechanical walking beetle "exhibiting the several characteristic **elements** of the **correlation** apparatus" (p. 341). The beetle preceded GREY WALTER's *Machina Speculatrix* and A. DUCROCQ's electronic foxes by more than 20 years. It also was an early form of **regulation** through **feedback**.

The term "depictor" never became established.

0859

DEREALIZATION ³⁾⁴⁾

The artificialization of our contact with the real world due to the growing use of **communication** technologies.

C. EMMECHE explains this as follows: "The mass **media** create their own world, an hyper-reality where the gap between **image** and **reality** is erased because everything is mediated, filtered through commentators, news bureaus, **images**, standardized analyses, talk shows, and **events** that are chosen and staged for the occasion. The **media** coverage of an **event** becomes the **event's simulation**, a complicated **game** that for all parties becomes more real than **reality** itself" (1994, p.158-9)

"**Simulation**", with its different psycho-social and computer science shades of **meaning**, is of course becoming one of the master **concepts** of our time. One could however think that in the whole span of existence of human race, our view of the "real" world has always been perceived and simulated - through the filters of myths, **religions**, philosophies or **ideologies**, as instruments to insure the cohesion of **socio-cultural systems**. So-called "derealization" seems in fact to be the contemporary way to generate a new kind of **self-reproducing (autopoietic)** "social cocoon", which appears to have been an ever permanent feature of social and cultural **human systems**.

From the cybernetic and systemic viewpoint, a deeper **epistemological** evaluation of the origins and the scientific and social nature of our **models** would be important. The **emergence** of the **systemic-cybernetic approach** probably signals a decisive mutation for the **understanding** of the collective **behavior** of human masses.

The new situation itself would thus generate the conceptual tools for its own **understanding**.

→ **Deconstruction**

0860

DEREGULATION ⁴⁾

A turn-back from artificially introduced **control-aiming regulations** to natural ones.

A bone of contention is to define what natural **controls** are and which **criteria** are used to distinguish them from artificial ones.

Deregulation, in social or economic systems, does not imply that no **order** whatsoever will remain into the deregulated system, but merely that the "visible hands" are to be replaced by the "invisible hand" (or hands!). Natural **regulations** are largely automatic (as in **ecosystems**, for instance), even if and when tampered with by a *number of different* actors.

In social and economic systems, deregulation easily leads to detrimental consequences for some **stakeholders**. Of course, this also is frequently the case with introduced **regulations**.

0861

DESCRIPTION ³⁾

Description is necessarily done by an **observer**, (or a group of them).

Awareness of "something there out" implies some **change** "here in". In von FOERSTER's words: "Terminal **representations** (descriptions) made by an **organism** are manifest in its movements; consequently the logical **structure** of descriptions arises from the logical **structure** of movements" and this is the case for "the two fundamental aspects of the logical **structure** of descriptions, namely their sense (affirmation or negation) and their **truth value** (true or false)". As a result: "The **information** associated with a description depends on an observer's ability to draw inferences from this description" (1981, p.262-3).

Synthetically, any description is by somebody, in this somebody's terms. von FOERSTER closes the circle, by saying: "The **environment** contains no **information**: the **environment** is as it is" (ibid).

Thus, as stated by A. GOUDSMIT: "...description takes place through the interactive **behavior** itself: it is the **activity** of specifying **distinctions** in the **environment**" (1989, p.172).

Interactive **behavior** supposes that the system (**observer**) is equipped to somehow perceive the **inputs** that will lead to the description. An interesting example are the sunburns by infrared or ultraviolet radiations. When we receive them, we are still unaware of the burns in the making. Since the **effect** is **delayed**, we will be able to describe the sunburns only later on. And, as we cannot directly perceive many electro-magnetic radiations, we are able to describe them only through their *perceived delayed effects*. (two centuries ago, nobody was even aware of their existence).

R. LILIENFELD observed that: "It is possible that "explanation" is a form of **knowledge** that is both secondary and defective and that another, and neglected, form of **knowledge** must precede it. This neglected form ... would be something called description" (1979, p.6).

H.H. PATTEE, on the other hand, states: "Description is not simple". He sees this as a result "... from our inability to reduce the number of **elements** and the number of **rules** that appear essential for the writing and reading of any **structure**" (1977, p.261).

He offers various possible explanations of this inconvenient situation: "First, there is the requirement in formal systems for explicit **representation** of every **change** of the system, whereas in physical systems the laws of motion involving real **space**, **time** and **energy** can take care of many **changes** without needing description...

"Second, the linguistic **rules** of formal descriptions can produce only **discrete** serial **operations** rather than **parallel continuous operations**. Construction, on the other hand, can often be performed most efficiently with **parallel** and coordinated **dynamics**.

"Third, interest in formal **programs** and **machines** usually depend on mathematicians' predisposition for generality or universality which greatly complicates their expressions" (ibid).

PATTEE went even farther and observed: "... the more you describe the measuring device, the less effectively it measures or describes the system" (ibid., p.262).

He also stated: "...what we measure is determined by what we choose to ignore about the dynamical details of a system" (1972, p.36). This is quite coincident with HEISENBERG's **indeterminacy relation**.

We are thus not only restricted in our **perception** of reality by sensorial limitations, but altogether in our description of it by our **modeling languages**, formal or just common. In L. LÖFGREN's words: "To notice that a describing system is influencing its descriptions does indeed suggest the idea that what can be objectively describe is limited" (1978, p.244).

This is in some way a startling generalization of HEISENBERG's **indeterminacy**! It also implies a significant limitation to the power of the **observer**.

PATTEE's conclusion: "However, until the essential **epistemological relation** between descriptions and **dynamics** is faced as a fundamental problem, I doubt if we can claim a useful theory of **complex system behavior**" (ibid., p.265).

0862

DESCRIPTION (External System's) ^{2) - 3)}

R. ROSEN distinguishes two kinds of system descriptions: external and internal (see hereafter).

According to him, the external description is the "**black-box**" description. He states: "In this **situation** we make no attempt to identify a set of **variables** for the system. Rather we have at our disposal a family of **perturbations** which we can apply to the system, variously called forcings, or **inputs**, and one or more observables which we use to index the **effect** of applying a particular forcing or **input** to the system. Such system observables are generally called system **outputs** or **responses**" (1972, p.51).

This kind of description allows for a better **understanding** of the relevant **environment** of the system and its impacts on the same, but does not easily enlightens the **autopoietic** characteristics of the same.

0863

DESCRIPTION (Internal System's) ^{2) - 3)}

This is the traditional way of description.

R. ROSEN states: "Typically such a description begins with a characterization of what the system is like at an instant of **time**; such a characterization is said to define a *state* of the system. The totality of all the possible **states** of the system, meaning the totality of different aspects the system can assume for us at an instant of **time**, forms a set called the *state space* of the system" (1972, p.50).(with the corresponding **state variables**).

This is satisfactory for **linear** systems, but quite insufficient for **nonlinear** ones. In these cases, at least two essential characteristics of the system escape to this kind of internal description:

- the mechanism of **self-catalytic hypercycles**, which describes how some **states** are regenerated from other **states**;
- The **organizational closure**, closely related to the former **mechanism**, which determines which **states** are admitted and which ones are excluded, in order to maintain the system's **identity**.

0864

DESCRIPTION (Self-) ²⁾ - ³⁾

H. PATTEE states: "The fundamental fact of life – a fact of such universality that it may be used to define life – is that *living systems contain their own description*" (1977, p.259).

This fact is closely related to **autopoiesis**, which would be impossible without the existence of a **specific template**, containing the basic traits of any individualized entity. Self-description also would be a condition for self-reproductive artificial **automata**.

Nevertheless, L. LÖFGREN observes: "It is important to clarify PATTEE's statement that *"complete self-description of any system is a physical impossibility, though not a logical of formal impossibility"*. LÖFGREN observes: "If complete self-description is meant to describe all of the description **process** itself (including both description and interpretation), then it is *logically impossible*. This has been shown by TARSKI, and somewhat later by GÖDEL" (1979, p.247).

The incompleteness of self-description explains why no system is ever able to reproduce itself *forever*. It is **autonomous** and **organizationally** closed, but never **independent** of basic conditions that transcend it.

0865

DESCRIPTION THROUGH HIERARCHICAL LEVELS ³⁾

H. PATTEE states: "The scientific description of **events** would, in fact, get nowhere in nature's maze of **complexity** unless there were repeated resimplifications which we call hierarchical levels of description" (1972, p.37).

He adds: "In fact every **process of classification** implies the grouping under a single **class** of **objects** which, according to a more detailed **classification**, fell in more than one **class**" (ibid).

While "description" is a mental artifact, it need not be arbitrary, since it is related to **levels of action**. We describe, for example social **interrelations** between plants, animals or men, putting into mental brackets the physiological, biochemical or physical **levels of action**, but this does not mean that we ignore their existence and fundamental importance. Moreover, we more or less clearly perceive **organizational analogies** between these **levels**. An outstanding example are the **crosslevel hypotheses** of J. MILLER in his "**Living Systems**".

0866

DESCRIPTIONS (State and Process) ³⁾

H. SIMON makes the following point: "A circle is the locus of all points equidistant from a given point... To construct a circle, rotate a compass with one arm fixed until the other arm has returned to it starting point. It is implicit in EUCLID that if you carry out the **process** specified

in the second sentence, you will produce an **object** that satisfies the definition of the first. The first description is a state description of the circle, the second one a process description" (1965, p.73).

While this is well known, it is quite frequently forgotten in practical management of **complex systems**: Many costly errors result from **actions** on a **dynamic system** made on base of a static state description.

0867

DESIGN ¹⁾

1. "A procedure aimed at the solution of certain non-trivial practical problems, or..."

"... a methodological **phenomenon** of the practical sciences" (W. GASPARSKI, 1993, p.407).

GASPARSKI gives us a systemic **evaluation** of the more classical **methodology** of design. Commenting his two definitions, he writes: "The former... may be defined as the **methodology** sensu stricto, whereas in the latter, the **methodology** of design is tantamount to the **methodology** of the applied (practical) sciences. There are also definitions which treat jointly both **concepts**, as one whole; these may be called the **methodology** of design sensu largo" (ibid).

About design as a technique for "constructing things", T. KOTARBINSKI, as quoted by GASPARSKI, wrote: "Saying of someone that he is constructing a design of a certain thing, we usually mean that, having decided to accomplish a certain task or to advise its completion, he endeavours to contrive the conditions necessary for carrying into effect that task, i.e. work or product... Any engineering specialization (science of bridge construction, machine construction, etc.) may be called a practical science, since it is primarily concerned with designing" (p.408).

Classical design starts with the definition of the **problem** to be resolved, through the analysis of the existing system. It defines the scope of a project to modify it and it studies the feasibility of the same. The design phase by an expert or a board of experts consists in the authoritative description of the proposed new system and of the steps to implement it. Consultations rarely cross the limits of (limited) technical **assessment** and mostly disregard other and more general aspects. It is very seldom socially participative.

In fact, such a formulation, while not objectionable per se, forgets the human aims of design: We **want** to construct "things" because we pursue personal and social **goals**. Thus design is not merely a technical endeavor.

As observed by E. STOLTERMAN: "It is not only **knowledge** about *how to design* that is needed. I think that to be a good designer it is of utmost importance to have **knowledge** about design. It is important to reveal hidden

preconceptions and **assumptions** about design practice. This has to be done by questioning the traditions and **values** predominant in the specific design area. Design **learning** should not be a **process** of conservation where existing practice is taken for granted and the only answer. Design **learning** is not a question of a simple transfer of established **knowledge** from experienced designers to inexperienced designers" (1992, p.1028).

It is now moreover becoming obvious that design should include a previous critique of these aims from various angles as for example possible **long term** results and ecological soundness (see B. BANATHY's definition and comments).

GASPARSKI thus quotes S.A. GREGORY, who makes the point: "The science of design should develop all **interdisciplinary** potential and employ not only the achievement of disciplines concerned with detailed design, but also of managerial science, **systems engineering**, and those aspects of behavioral sciences which deal with designing, designers, design institutions and social implications of design" (p.413).

Unfortunately, such aspects of behavioral sciences are still somewhat embryonary, in spite of ACKOFF, BANATHY, CHECKLAND, CHURCHMAN, van GIGCH's and others efforts.

2. "A creative, **decision-oriented**, disciplined enquiry" (B. BANATHY, 1988, p.27).

B. BANATHY gives the following explanations about his systemic **concept** of design: "(it) first clarifies the reason for engaging in design, and then diagnoses and describes the design problem **situation**; formulates expectations, **purposes**, and requirements of the system to be designed or redesigned; generates and clarifies alternative **representations** of the system that can meet those requirements and expectations; devises **criteria** by which to evaluate those alternatives; describes the most promising alternative and prepares a plan for the development and implementation of the selected design" (ibid).

And still: "Design will take on the characteristics of **learning**" (ibid., p.30).

Some supplementary pre-requisites seem necessary:

1) One great danger at the beginning of the design **process** is the "ignorance of ignorance" (J. FOURASTIÉ), or the "**invisibility**" problem (G.DE ZEEUW), or "**underconceptualization**" (J. WARFIELD). When we ignore some basic aspects of the **situation**, we may very well formulate, or worse, tacitly believe in incomplete or even false **assumptions**. In this case, all our design will rest on shaky foundations. We have thus a very important preliminary difficulty to solve: How do we get "out of our system". This could be called the "perceptive problem".

2) We should not ignore, or at least should try to become conscious of our own socially and culturally conditioned **mindscapes** (M. MAR-

UYAMA), which may in many cases, distort our **perceptions** and **understanding**. This could be called the "ideological distortion".

BANATHY is obviously aware of these problems as he emphasizes the need for: "front-end analysis/diagnosis of the design problem **situation**: **clarify** organizational culture and reason for design, formulate organizing perspectives that guide the design, explore barriers that prevent/hinder our continuing development, develop a rich picture of the design problem **situation** and, display a systemic analysis and structured **description** of the design problem **situation**" (p.33).

Still, how do we take distance from ourselves, as "**autopoietic** thinkers" (or tinkers!)?

For a quite complete overview of the systemic concept of design as seen by all significant authors in the field, the paper on "the practice and ethics of design" by K. BAUSCH should be consulted (2000, p. 23-50)

0868

DESIGN CONVERSATION^{1) - 4)}

A **methodology** of design to be applied to specific issues or tasks in organizational and social settings.

B. BANATHY, who advocates the methodology, sees it as a combination of **generative dialogue**, used to reach a common **frame** of thinking, and **strategic dialogue** in which specific issues are considered. (1996, p.39).

For practical uses, both types of **dialogue** are complementary and necessary.

0869

DESIGN (Co-participative)^{1) - 4)}

A design **process** in which each and every **stakeholder** takes part.

The classical design **process** of some specific project by experts – generally without due consideration for the **context** – leads evermore frequently to great disasters (C. FRANÇOIS, 1989, p.1101-11).

This is a result of single mindedness of the over specialized experts or pressure **groups**.

The only way to acquire a good **understanding** of the multiple aspects of any **situation** is to consult and listen to **all** those who are enmeshed in it and, when possible after giving them the suitable **information**, discuss the critical points with them in order to reach consensual conclusions and **decisions**.

Such a **process** could be long and painful, but it is the price to be paid in order to avoid still more painful and, in many cases irreversible negative results. Moreover, with time, better co-participative design **methods** will hopefully be developed.

0870

DESIGN CULTURE (System-oriented): The CHIOS DECLARATION¹⁾²⁾⁴⁾

A. COLLEN and W. GASPARSKI (1995, p.453-55) reproduce the following **concepts** formulated in this declaration by the participants of a Workshop on Developing a Design Culture in Higher Education that took place on the Island of Chios in Greece (1988).

The Declaration appeals for "a system-oriented design culture as an alternative culture to cope with the **complexity** of contemporary world"

"The culture is defined by the following four **goals**:

"1. To develop articulated design philosophy that can be accepted to guide intellectual leadership to creating the culture.

"2. To develop a suitable **language** for communicating design **concepts**.

"3. To create a better balance between **analysis** and **synthesis** in **education** and practice.

"4. To create a less restrictive but still definite view of what constitutes acceptable scientific **knowledge**".

The following suggestions were made to enhance the quality of design in systemic terms:

" - Open discussions on design culture with the participation of non-design culture oriented people (from academia, specific design professions, and laymen) should be organized.

" - Widely defined **multidisciplinary** research **groups** should be introduced.

" - A common **understanding** of the **concept** of "design" and its connection with **systems theory**, **planning**, **strategic management**, and other relevant **theories** should be developed.

" - The presently existing conceptual scheme of **systems thinking** and a system based **design theory** with general acceptability to the relevant view of **human action** should be completed.

" - The design theory should be positioned within the wider outlook of **systems sciences** and curricula that teach it as a core subject at the M.S. and Ph.D. levels, should be developed.

" - **Social system models** of an operating design culture in higher **education** should be developed.

" - A devoted **multidisciplinary group** of people to play the leading role in the spread of design culture should be developed,

" - The maximum possible **resources** to these areas of science that will offer the means to the society to take full and quick advantage of a new integrated **language** culture should be allocated".

By way of conclusion, W. GASPARSKI quotes H. SIMON, who wrote in "The Science of Design": "The real subject of the new intellectual free trade among the many cultures are our own thought **processes**. We are importing and exporting from one intellectual discipline to another ideas about how a serially organized in-

formation-processing system like a human being – or a **computer**, or a complex of men and women and computers in organized **cooperation** – solves problems and achieves **goals** in outer **environments** of great **complexity**

"...we can conclude that, in a large part, the proper study of mankind is the science of design, not only as the professional **component** of a technical education, but as a core discipline for every liberally educated person" (1981, p. 159)

0871

DESIGN (Generic)^{1) - 2)}

"That part of the **process** of design that is indifferent to what is being designed, being applicable whatever the target may be" (J. WARFIELD, pers. comm.).

To generic design, WARFIELD opposes specific design, "that part of the **process** of design that is particular to the target class" (ibid).

Targets can be for example a product, or a system that, in turn, can be "tangible or intangible".

WARFIELD enounces 32 basic postulates of Generic Design, related to:

- "The human being (7)
- "**Language** (6)
- "Reasoning through **relationships** (2)
- "Archival **representation** (6)
- "The design **situation** (2)
- "The design **process** (9)

WARFIELD's Generic Design methodology has been applied in a number of countries in Europe, Asia and both Americas. For a complete exposition of the **methodology** see bibliography (in particular: 1990, d).

0872

DESIGN (Heterarchical)^{2) - 4)}

A **model of organization** in which each participating **element** is more or less multivalent and, to a point, able to fulfill various **roles** in a **co-participative** way.

This **model** has been mainly developed by J. A. JOHANNESSEN and his co-workers (1991, 1992, 1993).

0873

DESIGN INQUIRY²⁾

A research centered "on the possibilities for **structural**, **functional** and transformational **changes** in **Human Activity Systems**" (A. COLLEN, 1992, p.563).

COLLEN comments: "The long standing preoccupation in institutions, corporations and governments with strategic **planning** does not serve well the **long term processes** of societies and the planet... and the growing **interde-**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

pendence among nations and transnational corporations confronts those in the most industrialized societies in particular with a startling challenge to an established way of life" (Ibid).

The most important need is a satisfactory **understanding** of the complex present **interrelations** of the system to be modified, with its **zone of activity** in its **environment**. In particular, much care should be taken about the "**invisibility**" of some aspects of the **situation** under consideration.

Designers should also research carefully the possible unforeseen consequences of the **changes** they wish to introduce into the system, in view that the positive sum **game** is quite generally a fallacy: desired **changes** are to be paid for, somehow, sometime, by somebody or by the **environment** (with probable **feedback**, according to the "no free lunch" principle), and it is better to know the price, or at least to try to know it before taking any irreversible **decision**. This is best done when every **stakeholder** is duly consulted.

0874

DESIGN: Its program ¹⁾²⁾

W. GASPARSKI et al. select the following aims and **contents** for design, as enunciated by a number of authors from 1936 to 1972 (for details see 1995, p.17-18):

"**Diagnosis** of practical **situations**, investigation of principles and **methods** of design realization" (KRECZKOWSKI, 1936)

"**Knowledge** concerning physical and economic **interdependences** and psychological conditioning of technical production (F. KESSELRING, 1954).

"**Normative knowledge** of principles and **procedures** of design and **methods** of **evaluation** of design solutions" (K.L. GREJNER, 1963).

"Studies, research, and accumulation of **knowledge** on the design **process** and its component **operations** as well as social conditioning" (S.A. GREGORY, 1966).

"Science related to the problems of "artificiality" of man-made products as opposed to natural products. It comprises: theory of the **evaluation** of the design results, logic of **synthesis**, theory of **structure**, formulation of design problems, and design **organization**" (H. SIMON, 1969).

"Theory based on mathematical **methods**, particularly on **decision theory**" (M. TRIBUS, 1969)

"General theory of design practice, aiming at development of "design **consciousness**" involved in the **process** of social **changes**" (T. MALDONADO, 1972)

"Philosophy and logic of design based on the adapted program of **methodology** of sciences by ADJUKIEWICZ. It differentiates between the theory of the **object** of design (apragmatic **methodology**) and the theory of the design

process (pragmatic **methodology**). Object of design and design **process** are considered as ideal types. General and detailed **methodology** are differentiated" (W. GASPARSKI, 1972).

Bela H. BANATHY and J. WARFIELD - among others - have also signaled other important aims and **methods** (See other entries on "design")

0875

DESIGN METHODOLOGY (Systemic) ^{2) - 4)}

B. BANATHY proposes the following design methodology, in correspondance with his general systemic **understanding** of what design should be in order to be creative and adaptive, as well as better tailored to human needs (1988, p.32):

"The system creation is carried out in the design solution space, which is surrounded by the design genesis space, the design **experimentation space**, the space in which we organize **knowledge** that informs our design, and the space of the future system.

"In the contextual/design genesis space, the stage is set for design. In this space we reason for design, formulate organizing perspectives that shall guide design thinking and **action**, and develop a rich picture of the design problem **situation**".

Of course, in this statement, the most important word is "we". The identity of the designers, their stated or unstated **goals**, their prejudices, their mental **frames of reference** are of utmost importance. Here, systemic design parts company with classical design, which (in societal "engineering") is generally authoritarian and speciality bound.

BANATHY proceeds: "In the organized **knowledge space**, **information** and **knowledge**, pertinent to design inquiry, are continuously infused and organized to inform design in a timely fashion and provide substance to the generation of alternatives.

"The experimentation space is created in order to allow for design experimentation and the testing of emerging design alternatives as well as the **assessment** of the on-going design itself.

"The space of the future system will contain the **model** of the system to be designed as well as the **model** of the systemic **environment** of the future system.

"It is the **design solution space** in which we formulate the **image** of the future system. In this space, **design inquiry** is carried out in a spiralic manner as we explore and re-explore the various spaces of design inquiry... and integrate **information**, **knowledge** and experience into the emerging **image** of the future system" (Ibid).

Thereafter, BANATHY enumerates the successive stages of the **design inquiry**:

"Stage one: front-end analysis/ diagnosis of the design problem **situation**: clarify organizational culture and reason for design..., formulate organizing perspectives that guide the design, explore barriers that prevent/hinder our continuing development..., develop a rich picture of the design problem **situation** ..., display a systemic analysis and structured **description** of the design problem **situation**.

"Stage two: the design of the ideal system: formulate expectations, **purposes**, and aspirations of the future system..., formulate a root-definition of the system..., select type of system we want to become (e.g. **purpose-seeking**)..., formulate desired system characteristics..., explore and evaluate alternative **configurations** of **functions** by which to attain stated **purposes**..., select and test and describe the ideal system.

"Stage three: the design of the enabling system: the design of the **management system** and the organizational design that enable us to move toward the realization of the ideal future state.

"Stage four: the implementation **planning** stage: **planning** the **means** and **methods**... and the **strategies** ... by which we can implement the feasible and attainable **representation** of the ideal design and develop the enabling systems, and design the change delivery system."

There is of course a general caveat: BANATHY's approach is ethical and idealistic. It could however be distorted by ideological biases (conscious or unconscious), as well as by specific pressure **groups** interests.. This in turn offers curious implications: if all the participants in the design **process** share the same prejudices - even (in our own view) harmful ones - they would be in their right to proceed, as long as they do not provoke problems outside their own **domain**, ...or are supposed not to.

Design "a la BANATHY" should always be as much **co-participative** as possible, precisely to obtain a maximum opening of the spaces and **stages** he describes, and a genuine (and adaptive) **consensus**.

0876

DESIGN or PLANNING? ²⁾

E. JANTSCH proposed the two following basic **rules** "for purposeful **organization** or **planning**":

"1. Make **structure** as flexible as possible, so that it can be changed by emergent **changes** in the **interaction** of **processes**; and
"2. identify and enhance evolutionary **processes** of **change**, recognize and respect their self-bounding nature" (1975, p.63).

These **rules** (themselves part of a good **understanding** of the nature of systems) seem also absolutely needed for defining clearly "the vision of what should be" in systems design as proposed by B. BANATHY, if biases of any kind are to be avoided.

If so, **planning** will probably converge into design in a not too faraway future.

0877

DESIGN (Systemic approach to)²⁾

B. BANATHY writes: "In sharp contrast (with the traditional social **planning**) the systems design approach seeks to understand a problem **situation** as a system of interconnected, interdependant and interacting **problems**, and creates a design solution as a system of interconnected, interdependent and internally consistent solution ideas. Design is a journey by which we can bring about a desired future **state** of our system" (1992, p.550).

According to BANATHY the design **process** goes through four successive stages:

1) Formulate the core definitions about the nature of the system and the vision of the **stakeholders**.

2) Develop the specifications, as for example services to be offered by the system, in which way and to whom, ownership, **rights and responsibilities**, etc...

3) Design the system of key and **subfunctions**, to be arranged in a coherent way.

4) Design the **organization** on the base of the **functions** to be fulfilled and the practical possibilities to fulfill them.

BANATHY refers himself to systems design as to a "journey", emphasizing its dynamic character. It should be added that the design **process** of a system never ends as circumstances are permanently changing. Moreover, the results of **action** are to be repeatedly monitored and fed back to the **process**, in order to introduce possible corrections.

0878

DESIGN (Systems)^{1) - 2)}

"The full scope of **activities** by which we attempt to construct systems that are adequate **models** of desirable man-made **objects**" (G. KLIR, 1993, p.30).

This implies that the "desirable artificial **object** can be constructed in such a way that relevant objective **criteria** are satisfied within given **constraints**" (ibid).

The definitions of what is desirable and what are objective **criteria** are of course difficult to establish. Also, "**objects**" can be abstract: research projects, institutions, **social systems modes** of **organization**, etc.

This point is made by B. BANATHY: "Systems design in the **context** of social systems is a future creating disciplined **enquiry**. People engage in design in order to devise a **model** of a

system, based on their vision of *what should be*. They seek to create a design that has a "goodness or **fit**" with their larger society and with their own expectations..."

"This approach is very different from the widely practiced traditional social planning, which reduces the problem to manageable pieces and seek solutions to each" (1992, p.548).

In accordance with BANATHY, ACKOFF writes: "To design a system is to develop a **representation** of a system that does not (*yet*) exist" (1988, p.245).

Some important points should be noted:

- the design escapes from the dangers of ideological bias, if *people*, i.e. each and everyone of the "**stakeholders**" in the project effectively and personally participates in the **design process**.
- and if the whole area of possible **situations** is duly explored by the **community** of participants.
- experts are to be consulted when needed, but are not to be placed in the position of all powerful **deciders**.

0879

DESIGN: The BOSTON MANIFESTO¹⁾²⁾

Prof. G. NADLER produced this Manifesto at a Congress in Boston in 1988. The following excerpts are quoted from A. COLLEN and W. GASPERSKI (Eds.) book on "Design and Systems" (1995, p.452-3)

"**Planning** and designing have the purpose of creating or restructuring a system or a solution for specific **situations**. Successful **planning** and **designing** produces effective and possibly innovative recommendations for systems (products, buildings, **information flow**, **organization**, etc.) that are implementable. P&D is defined as the **process** or **approach** mode to connote the continuing need and nature of creation or restructuring systems in our world. Plans and **design** describe the results (recommendations and solutions) of the P&D **process**".

...The Manifesto proposes the following agenda:

- To encourage scholarly and practitioner discourse (set up a **network**)
- To institute **procedures** for the further **interdisciplinary** development of a systematic body of **knowledge** about **planning** and **design**
- To set up international standards for research in P & D **theory** and **methodology**
- To assist in the dissemination of new **knowledge**, through publications, workshops, conferences and other such media
- To promote the study of actual **planning** and **design** practices, and to analyse their respective strengths and weaknesses, and to evaluate their **effectiveness**

" - To support the development of **methods** and **tools** for the enhancement of **planning** and **design**

" - To encourage the professional schools to emphasize **design theories** and **methods** in their curricula

" - To serve as a **coordination** group for and a **stimulus** to P & D groups in each of the P&D professional areas (e.g. engineering, architecture)

" - To foster public **awareness** of the significance and importance of the activities of **planning** and **design** and their various approaches

" - To work on the development of a P & D Honor Society" (p.453)

Most of these recommendations are basically instrumental in a practical sense.

For more elaborated concepts on "a system-oriented design culture", see hereafter.

0880

DESIGNATA¹⁾³⁾

The objects symbolized by the **signs** used to represent them.

This relation between the **objects** and their designata is the main concern of **semantics**.

0881

DESTABILIZATION (Signals of impending societal)^{1) - 4)}

K.E.F. WATT and Paul F. CRAIG suggest seven kinds of signals of impending societal destabilization:

1. Dangerous **dependence** on a single critical limiting **resource** at risk of near-term supply curtailment
2. A dangerously coarse-grained **environment**
3. Lack of **redundancy** in the social infrastructure. (What do we have already in place to allow us to survive sudden curtailment of petroleum supplies?)
4. Lack of fast-acting **negative feedback loops** in **complex systems** of impending **resource** shortages, sets systems up for shocks
5. Top-heavy, multi-layered, rigid **organizational structures**
6. Curtailment of migration because of prohibitive **resource costs**
7. Excessive **connectance** between the economics of different nations means that now, a shock anywhere translates into a shock at other, remote sites" (1986, p. 200).

Some of these **signals** at least are valid for enterprises, individuals and, in ecological settings, for species.

0882

DESTRUCTION

→ **Self-destruction of systems**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0883

DESTRUCTURATION ¹⁾ - 4)

The loss of internal **order** in a system.

This is sometimes an *intermediate phase* in the existence of the system, preceeding a fundamental reorganization or a jump toward a higher **level of organization**. Its seems that the **elements** need at some moment be freed from their former **links** in order to re-arrange themselves into a new **structure**.

The cause and reasons of this **phenomenon** have not yet been seriously explored.

A good example is moulting in insects. Another could (hypothetically) be revolutions in human societies.

Still another example is J. SCHUMPETER's "**Creative destruction**" (1954, p.161). According to this Austrian economist, every important economic evolution generated by technical **progress** starts inevitably with the **destruction** of a number of old **structures** - trades, businesses, **rules** - not anymore adapted to the new conditions. This leads to a restructuration, generally much more varied and complex, with new trades, new products and wider and more inclusive **rules**, which allow for further economic **progress**.

E. KAHLER (1968) describes the same **process** in the 20th. Century arts, at least in terms of general desintegration of **form**. Remains to be seen if a restructuration will take place in the future.

0884

DETECTION (Delayed) ²⁾³⁾⁴⁾

In many systems submitted to study by **observers**, some **effects** are not, or only very lately, registered.

The causes may be of different orders:

- the effects are small and only accumulate in the long **term**, thus escaping the gaze of the circumstantial or casual observer
- the effects are of a new type and the observer lacks the mental **reference frame** for their **understanding**, or even their **perception**
- the effects are still potential, as possible consequences of other **events** ignored, misunderstood or considered irrelevant by the observer. This is particularly true for new technologies or faraway **events**.

These various factors produce some common results. The observer is taken by surprise and frequently quite unprepared to react efficiently. Such a situation may be very damaging for the observer and/or for the system itself.

However, as noted by K. MATSUNO, when various effects of different nature are acting simultaneously in a system and, in cases, out of the **phase**, a global possibility for **adaptation**, or even **evolution**, becomes stimulated (1998). In such a situation, early detection is even more important.

→ **Time horizon; Time lag**

0885

DETECTOR ¹⁾ - 2) - 4)

Any device usable to discover and measure some characteristic of an **environment** or a system.

In biological systems, the famous "**Frogs Eye**" experiment by J.Y. LETTVIN et al. "... showed how the built-in classes of visual detectors in the frog's retina correspond to perceptual **categories**" (J.L. SNELL, 1988, p.360).

This also shows that biological detectors have an ingrained evolutive history and are not only detectors but moreover **selectors** and **transducers** whose transparency is far from total. (See LOTKA's concept of **descriptor**). It would be interesting to define and study the nature of social detectors. **Values, norms, ideologies**, etc... are probably such social selective detectors.

0886

DETERIORATION ¹⁾

A **process** of progressive **decay** that affects the **structures** of any system through **time**.

Deterioration is an unavoidable consequence of the **2nd law of thermodynamics**. It can be avoided during a more or less long span of **time** if the system disposes of self-**maintenance** devices, for which of course a price in **energy** use must also be paid.

This notion is very important, because it constitutes the perceptible **nexus** between **time** and **energy**.

0887

DETERMINATION ²⁾

The way the present **state** of a system has been reached as a result of the sequence of its former **states**.

W. KARGL writes: "The global past of an individual system does not condition in an absolute way its future, but only the **distribution** of its possible future **states**" (1991).

0888

DETERMINATION (Multiple) ²⁾ - 3)

The **effect** on **behavior** of a number of **simultaneously** convergent **causes**.

G. BATESON gives a striking, everyday life example: "We turn off the light when we go to bed, influenced partly by the economics of scarcity, partly by premises of transference, partly by ideas of privacy, partly to reduce sensorial **input**, etc..." (1973, p.476).

Unfortunately, our belief in **linear causal determinism**, acquired through traditional training, many times blinds us to multiple determination and leads us to gross and at times, dangerous simplifications.

0889

DETERMINISM ¹⁾ - 3)

"The belief that the future **state** of a system is completely determined by its present **state**, the same **causes** producing the same **effects**" (E. SCHWARZ, 1993, p.4).

This at least, is a definition specifically formulated in relation to systems.

SCHWARZ states, rightly it seems, that determinism is a belief, resulting of an **epistemological** attitude.

Determinism is one of the most abstract and ill-interpreted concepts in the history of science and philosophy. As noted by G. ISRAEL, numerous definitions have been given and the concept appears on different conceptual **levels** (1992, p.252).

Misunderstandings about determinism lead easily to misinterpretations about **complex systems behavior**. While necessarily very sketchy and inconclusive, a discussion of the subject is unavoidable.

To begin with, determinism cannot be reduced to a **principle of absolute causality**, that has been "...the dominant metaphysics of modern science" (p.253).

The word appears in Germany during the 18th Century (LEIBNIZ), but is imposed by Cl. BERNARD in France, around 1860: "There is an absolute determinism in all sciences", or "It should be admitted as an experimental axiom that in living beings as well as in raw substances, the conditions for the existence of any **phenomenon** are determined in an absolute manner" (1952, p.111). He however repented somewhat later on: "When I introduced for the first time the word *determinism*... I was not thinking that it could be confused with LEIBNIZ philosophical determinism" (1878, p.55)... However, it was!

G. ISRAEL concludes: "Last century's scientific determinism is an **epistemologic doctrine** deriving from Cl. BERNARD's thesis" (p.257). As a result, determinism seemed to have an absolute **ontologic** value.

No significant problem emerged from this viewpoint as long as science was directed to the study of **linear** or reducible to **linear processes**. The difficulties started on one hand with BOLTZMANN's statistical **thermodynamics**, and on the other with POINCARÉ's **3 bodies problem**, which was a harbinger of **chaotic behavior** of systems with **sensibility to initial conditions**.

Thus seemingly **random transformations** in the systems **behavior** started to mix a statistical aspect with a kind of diffuse surviving determinism. As with quanta, relativity and Prigoginian **thermodynamics**, clearcut, absolutist concepts of the past have to give way to more intricate and subtle **models**. "Cause" becomes now a complex **web of causes** and determinism becomes at the same time diffuse and generalized in **space** and **time**. It must fi-

nally be admitted that science only constructs general **models**, while any concrete **phenomenon** is a particular case, because it is a specific result of a unique, but complex **history**.

0890

DETERMINISM (Chaotic)→ **CHAOS (Deterministic)**

0891

DETERMINISM (Concept of absolute)³⁾

"The theory that the **behavior or processes** of systems can be precisely and fully forecasted" (Adapted from J.Z. YOUNG, 1978, p.291).

YOUNG claims that the concept must be "considered to be meaningless because no such principle can be demonstrated".

The concept of absolute determinism was enunciated as follows by LAPLACE: "An intellect which at a given instant knew all the forces acting in nature, and the position of all things of which the world consists – supposing that said intellect were vast enough to subject these **data** to analysis – would embrace in the same formula the motions of the greatest bodies in the universe and those of the slightest atoms; nothing would be uncertain for it, and the future, like the past, would be present to its eyes".

Nobody can object such a statement, about a "theory of everything". But, obviously, no human being, nor any other living being possesses this Laplacean "intellect", as shown by relativity theory as well as by HEISENBERG's **indetermination** principle.

While LAPLACE's statement was unequivocally hypothetical and quite carefully worded, subsequent 19th century generations of scientists and philosophers adhered to the concept as if it were possible, true and necessary as a rigorous **causal** (and even sometimes mon-causal) principle that should be applied strictly to every kind of scientific work.

Indeed, various aspects of such an absolute principle and its applications came under close critical scrutiny during the 20th century:

1. Physicists have been compelled to admit a basic **indeterminacy** at micro-physical level. No "human intellect" can know "all the forces" and "the position of all things" at a given moment. This **situation** turns elusive the quest for causal determinism and future becomes **fuzzy** and not anymore rigorously **predictable**. **Observation** perturbs and non-**observation** leaves us in the dark.

2. It is not anymore evident that the Universe is globally and perfectly coherent. As **simultaneous** local causes cannot propagate instantaneously, global determinism, if it exists, breaks up locally everywhere: local and more or less provisionally disconnected determinisms appear and provide for a more or less **chaotic** and **unpredictable** future.

3. Any **universe** (or system) is at least partly blind to itself (see Jumarie's **relativistic theory of information** – 1980 and 1982). The only perfect **model** of the **universe** (or the system) is itself. This could lead to a very curious reformulation of LAPLACE's statement.

4. Our laws (deterministic or otherwise) are **constructs**, or **algorithms**. We acquire them by **consensus**, but they are never completely immune to **falsehood** "à la POPPER". We do read some measure of determinism in the universe, but we are safer **epistemologically** than **ontologically**.

As to systems, a **consensus** seems to be emerging: any system is governed by some basic determinisms at global or macro level, but its **organizational closure** provides it with a more or less broad measure of **autonomy**, i.e. the (determined!) capacity to determine itself, within **limits**.

It has ultimately become clear – through the theory and **models** of **deterministic chaos** – that determinism is necessarily **relative** due to the successive disconnections and reconnections of **simultaneous events in complex systems**. This introduces a relation of traditional determinism with the **reversibility** concept.

According to F. BONSACK: "When we look for an example of determinism, we readily recall two **phenomena**: the first, the collision of perfectly elastic balls, the other one, the rotation of the planets around the sun. One may make a remark that, at first sight, could look as anecdotal: both cases are related to **almost reversible phenomena**. Laplacean determinism is **reversible**: starting from time t_0 , one may compute the **state** of the system at a future time t_1 as well as at a former time t_{-1} . Moreover, in the balls **model**, one reaches a paradoxical **situation**: it is possible to go back earlier than the initial **situation**" (1983, p. 113).

The apparent paradox is a result of the ever recurrent confusion between the real **situation** and the **model** we use to describe it. **Reversibility** exists only within the conceptual **model**. The planet JUPITER has occupied, occupies and shall occupy (very probably) a certain position (related to an **abstract frame of reference**) on various moments of the past, the present (unique) and the future. But it cannot really backtrack in the **time dimension**. The various past and future positions are merely **computable**.

The real interest of classical determinism is of a practical nature: it permits to retrieve former **situations** and to predict future ones by computation, always within the **limits** – sometimes dubious – of the "...**et ceteris paribus**" principle.

F. BONSACK immediately makes the point:

"Laplacean determinism is **reversible**. But our familiar notion of **causality** is not: the **cause** is always clearly different from the **ef-**

fect and generally it is not possible to permute them. This means that there must be in our notion of causality something fundamentally **irreversible**" (Ibid).

For a very detailed discussion of this question, see F. BONSACK's paper.

V.V. NALIMOV makes a very interesting study of the origins and history of determinism in its pre-logical and logical development (1981 b, p. 90-95)

0892

DETERMINISM (Epistemic)²⁾

The concept of **causality** according to which "given a complete **knowledge** of the present **situation** (Cf. the demon of LAPLACE)... if we assume that all **events** are causally related, and that **causal** determination is complete, then we must conclude that the world is completely determined and that all future **events** are in principle **predictable**" (1989, p.362).

This is the general frame of all scientific theories seeking grand **algorithms**, including the would be "theory of everything", embracing all forces in nature.

However, as stated by R.N. ADAMS: "Determinism is a condition where **events** conform to our **models** to a high degree, but it occurs because (1) the **models** are apt for the particular set of conditions and (2) those conditions are highly **stable**" (1988, p.3).

0893

DETERMINISM (Historical)→ **Historical determinism**

0894

DETERMINISM (Internal) (or self-)¹⁾

All **living systems** are endowed with some degree of internal determinism, as shown by P. VENDRYES (1942), who refined the concept previously developed by Cl. BERNARD in the second half of the 19th century.

The living **organism** adapts itself to the variations imposed by its **environment**, thanks to internal **cybernetic mechanisms** of detection and **regulation**. These count with available stored **reserves** which allow them to compensate internal **fluctuations** which result from these variations. VENDRYES gave numerous examples: the **regulation** of the body's content of glucose, respiratorial **rhythm**, lipids **metabolism**, etc.

The global internal determinism guarantees **dynamic stability** of the system and assures it a degree of **autonomy** in relation to **environmental** determinisms. This is thus a kind of **countervailing** determinism.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0895

DETERMINISM (Ontic)³⁾

Until now, we have used the word "determinism" in an **epistemic** sense: "A theory was said to be deterministic if all the **distinctions** made within that theory were **causally** conserved. Ontic determinism then should mean that we would infer from the determinism of our theory (e.g. classical mechanics) that the real world to which the theory referred were also deterministic (e.g. the world of LAPLACE)" (F. HEYLIGHEN, 1989, p. 379).

Conversely, concepts like **simultaneity** in relativistic terms, **bifurcations**, **emergence** or **chaotic attractors** lead us to a kind of **ontological agnosticism**.

F. HEYLIGHEN asks: "Is **causality** "real" or "objective", and does it exist independently of the **observer** (ontic interpretation)? Or is it merely a **cognitive construct**, an association between subjective ideas or experiences (**epistemic** interpretation)" (p.362).

"We would, hence, tend to conclude that the question of whether the world is (ontically) deterministic is a meaningless one, to which all possible answers are either trivial or unprovable in principle" (p.379).

→ **Ontological skepticism**

0896

DETERMINISM, RANDOMNESS AND CHAOS^{1) - 3)}

The chaos concept leads to a deep questioning of the traditional- and absolute- notions of determinism and **randomness**, whose relation has now become quite blurred. Formerly, in the words of J. GLEICK: "Either deterministic mathematics produced **steady behavior**, or random external **noise** produced random **behavior**. That was the choice.

"In the **context** of this debate, **chaos** brought an astonishing **message**: simple deterministic **models** could produce what looked like random **behavior**. The **behavior** actually had an exquisite fine **structure**, yet any piece of it seemed indistinguishable from **noise**" (1987, p.78-79).

Through **chaos**, **randomness** seems to become **embedded** within a broad determinism, or put in the opposite way, in **complex systems**, a kind of **determinism seems to emerge from randomness**. Either way, determinism and **randomness** become closely intertwined.

The **embedding** is quite clear in the WEIERSTRASS function for example, or in the **fractal** expressions of **chaos**.

However, these formalizations are still mathematical **models** and one may wonder if they fully contain the **interrelations** between determinism and **randomness**. For the time being, the subject must remain open.

→ **"ergodicity"**

0897

DETERMINISM (Statistical)²⁾

Overall determinism observed through a **behavior** characterized by unvarying probabilities (Adapted from W.R. ASHBY, 1981, p.202).

In E. JANTSCH words "A statistical determinism has to allow for **random deviations**" (1975, p.201).

Statistical determinism is difficult to differentiate from **deterministic chaos**.

0898

DETERMINISM (Structural)²⁾

The **set** of basic conditions that allows the **autogenesis**, existence and **survival** of a system.

According to HARNDEN: "Such a determination is a two way dance in that the unity structurally determines its **niche** in the same move that its niche **structurally** determines it" (1990, p.300).

In other words, any system is at least in some measure **preadapted** to its **niche-environment**: it is an unavoidable previous condition of **survival**. However, as no **environment** is ever absolutely **stable**, the system must repeatedly adapt and readapt to outside variations, within the **limits** allowed by its own internal **variety**.

Thus, structural determinism is a global **frame** for **behavior**. but necessarily admits more or less ample **fluctuations**, which may even appear as **random**.

In very complex evolutive systems (**ecosystems**, **sociosystems**) structural determinism becomes so vast and complex that it practically seems to dissolve, giving much leeway to innovation and **creativity**.

0899

DETERMINISTIC PROCESS²⁾

P. VENDRYES writes: "...a deterministic process can be fulfilled in one, and only one, way.

"This condition of fulfillment has two consequences: (1) the deterministic process is **predictable**, and (2) it is in principle **reversible**. Therefore there are three characteristics of a perfectly deterministic process: uniqueness, **predictability** and **reversibility**" (1989, p.148).

Of course, real processes are not that pure: they have **contexts**. In a system, any process is functional or, eventually, abnormal or pathological and, thus, submitted to conditions existing within the system. The same is true for processes connecting the system with its **environment**. Many **events** that may influence the process do not depend from it and, moreover will put **predictability** more or less in jeopardy when they become connected.

0900

DEVELOPMENT¹⁾

The progressive unfolding of a system's **structures** and **functions** until it reaches its mature **state**.

Development is one of the most confusing and abused term in common uses. It is quite generally understood as meaning an increase of some quantitative factor. However, it is also used in a qualitative **meaning**: the internal differentiation of **structures** and **functions** in a system. Even in this case, it can be generally measured in terms of **variety**.

According to M. BUNGE, and from a biological viewpoint, "the development **process** of an **organism** has three main strands...

"1. **Growth**, or multiplication of **cells** of certain kinds (at uneven rates for different **subsystems**...)

"2. **Morphogenesis**, or formation of new **subsystems**

"3. **Differentiation**, or specialization of **cells**

"All three aspects of development proceed under a triple **control**: enzymatic, genetic and environmental" (1979, p.95).

Genetic would be a kind of master-plan originated in inherited characteristics. *Enzymatic* would be a global internally harmonizing **regulation**. And *environmental* would represent the external varying **constraints**.

This **model**, as a whole, could probably be translated to **organizations** and **sociosystems** in general.

From a **thermodynamic** viewpoint, development is either related to the **growth** of a given system, or to its eventual **transformation** through **dissipative structuration**.

In the first case, only a moderate **growth** of a system well defined by its **organizational closure** is possible until the system reaches its **level of dynamic stability**, as defined by the minimal internal **entropy** production compatible with its **maintenance** necessities.

In the second case, the system is forced out of its **dynamic stability limits** by growing **energy inputs**, that must be **dissipated**, but may produce growing internal **structuration** and increase the **level** of internal **entropy** production. Eventually, the nature of the system may be radically modified through **emergent complexification**.

However, even in such a case the new system, after the **emergence transition**, needs stabilize itself, i.e. find its proper **level of dynamic stability**.

A system that should not be able to limit its **growth**, i.e. that would become over-developed, would be in great danger to destroy itself due to the exhaustion of its **environmental sources** and/or **overload** of its **environmental sinks**.

0901

DEVELOPMENT (Biological)^{1) - 2)}

According to F. BAILLY, F. GAILL & R. MOSSERI, the development of biological systems is submitted to the four following specifications:

1. **Endomorphism**: "...autonomy of an entity whose developing rules are internal and given once for all (genetic endowment), correlated and **organizational closed** (in the **autopoietic** sense- MATURANA and VARELA)"
2. **Discontinuity**: corresponding to a "development by way of alternating of **activity** and **latency**, critical **periods** and punctuated **sequences**"
3. **Recursivity**: "corresponding to a principle of informative economy by the application of only one formal law, reiterated at every step of the development"
4. **Nonlinearity**: "corresponding to the **process** of growing **complexification** paired with **iteration**...(a **linear iteration** would be merely **additive** and could not explain progressive, **structural** and **functional complexification**" (1991, p.58).

An example of **linear iteration** is crystal growth.

It would be interesting to consider the **validity** of these specifications:

- a) for the general problem of **evolution** (crf. GOULD-ELDREDGE's punctuated **evolution**).
- b) in the case of more or less integrated **social systems**, such as ant nests, beehives, enterprises, human societies.

0902

DEVELOPMENT IN HUMAN SYSTEMS⁴

R. ACKOFF emits the following opinions about development in **human systems**:

"By *development* I mean an increase in the desire and ability of the **organization** to satisfy its own needs and legitimate desires, and those of others... By *legitimate desire* I mean one which, when satisfied, does not impede anyone else's development.

"As 1) development requires motivation and **learning**, and 2) nobody can learn for another, one person or **social system** cannot develop others. The only kind of development that is possible is *self-development*" (1988, p.241).

This viewpoint is consonant with B. BANATHY's and the FUSCHL Group's concept of **co-participative social design**.

ACKOFF states moreover: "**Growth** is not necessary for development, however much it may facilitate development in some cases... In some cases, **growth** is a means to development but it should never be an end-in-itself" (p.245).

These views are in near complete opposition to the dominant socio-economic theories of the 20th. Century.

Another necessity for non-destructive development in human systems is that it be *balanced*. According to M.M. DODDS and G. JAROS, such a balance must comprise four fields:

- 1) **Collective consciousness**
- 2) **Environment**
- 3) **Collective abilities**
- 4) **Organizational configuration**

These authors write: "Incongruences amongst the four fields outlined above can be seen to create a **variety** of development problems on a global **scale**. These include, inter alia, imbalances between **population size** and the carrying capacity of the natural **environment**; between the aspirations of societies and their competence to achieve them; incongruence between the managerial capacity/organizational ability and the socio-economic and political **environment** in which the system has to function. These **activity** fields need to be brought into balance" (1994, p.1422).

However, and very unfortunately: "The irony is that it is every person's responsibility, yet no one has the authority to do anything about it, therefore no one is accountable" (ibid.).

The only ways out of this dead end is probably **systemic education for everybody** (centered on *realist ethics*)..., which could require centuries, and some types of globally evolved constraints on **human systems**, as they will possibly result from natural limits.

0903

DEVELOPMENTAL PROGRAM

→ Program (Developmental)

0904

DEVIANCE^{1) - 2)}

The slow **drift** of a system away from its basic functional conditions.

Such a **drift** may lead the system toward an **instability threshold**. This in turn may become a positive or a negative factor.

It is positive when it corresponds to a more or less automatic capacity of **adaptation to change**, as for example physiological **adaptation** to high altitude.

It is negative when it implies the appearance of useless or nocive **constraints**, as for example excessive bureaucracy in a society.

0905

DEVIATION²⁾

A departure from the normal **state** in a **homeostatic system**.

The **amplitude** of a deviation can be a good indicator of the **stability** of a system. For practical purposes, it should be closely monitored. I. PRIGOGINE and P.M. ALLEN write: "If it decreases in **time**, then the solution is stable; but

if it grows in **time**, then the **state** is **unstable** because the least little **fluctuation** will be amplified in the system and drive it away from the **stationary state**" (1982, p.9).

0906

DEVIATION – AMPLIFICATION PROCESS^{1) - 2)}

A process resulting from constantly repeated **positive feedback**.

This type of processes correspond to M. MARUYAMA's "**mutual-causal relationships** that amplify an insignificant or accidental initial kick, build up deviation and diverge from the **initial condition**" (1963, p.165). It easily leads to **runaway situations** or widening **fluctuations**, sometimes destructive or, in other cases eventually conducive to **dissipative structuration**.

MARUYAMA describes these processes as resulting from **positive feedback** and leading to **morphogenesis**.

However some caveats should be taken in account:

- Any **unchecked positive feedback** leads unavoidably to the destruction of the system because it rapidly overwhelms the capacity of the **environmental sources** to sustain the **process** (Fires, hyper-inflation, market crashes)
- Amplified **fluctuations** may lead to **dissipative structuration**, as in PRIGOGINE's **thermodynamics**. In this case, they lead to the **emergence** of a more **complex system**.
- In MARUYAMA's examples **positive feedbacks** are generally controlled by self-limiting reciprocal **rules**, *within a limited substrate*. A constant **source of energy** is not specified, but obviously necessary. These are the factors that orient and put **morphogenesis** on a defined track. Such processes are quite similar to J. CONWAY's **games of life**. As understood by MARUYAMA, and according to R.L. HOLLOWAY Jr. "Deviation – amplification adds the dimension of **time** and direction to... the generation of **structure** by incorporating the necessary **loop of positive feedback**" (1966, p.7).

0907

DEVIL'S STAIRCASE²⁾

A **discontinuous** mathematical curve characterized by many **steps**, some small or very small and some large or very large.

This curve was introduced by the German mathematician Georg CANTOR (1843-1918). It was considered for long time a paradoxical and imaginary invention.

However, P. BAK uses it now in his **self-organized critical evolution model** for an approximate **representation** of **punctuated equilibrium**, as a description of **discontinuous** mutation jumps in **evolution**, some small and frequent, some others big, but very unfrequent.

0908

DIAGNOSIS in systemic terms¹⁾

We are accustomed to diagnosis of **linear problems** of the type: "The car does not start because the battery is flat". This is not enough for intricate **problems in complex systems** (ACKOFF's "messes")

In such cases, diagnosis should be preceded by a wide inquiry about the multiple historical and present intertwined factors that could have a bearing on the **situation**. These factors must first be brought to light through appropriate mental techniques in **groups** wherein *all stakeholders* are present or represented. Thereafter, their **meaning** and relative importance must be debated and evaluated. And finally, the **constraints** and **synergies** that they introduce must be discovered and also debated and evaluated.

Short cuts in this procedure are always risky, even if admittedly **design** and **decision time** are in short supply.

Ill-informed **action in complex systems** generally lead to unforeseen resurgences of **problems** under new aspects.

For practical methods, see J. WARFIELD (1994b).

0909

DIALECTICAL SYSTEMS THEORY¹⁾²⁾

This peculiar systems theory has been progressively elaborated by M. MULEJ from 1974 on, and constantly researched by Mulej and his collaborators at Maribor University (Slovenia) from 1992 to date.

The most recent definition of the "dialectical system" is as follows: "DS is a system of all relevant and only relevant/requisite viewpoints systems" (Ecimovic, T. et al., 2002, section 4.1)

The authors are conscious of the difficulty to reach **consensus** about what is relevant or not, and discuss this point.

They describe their view of the Dialectical System as follows: "It starts from the notion that a system does not exist, but the **object** does, and the system reflects it, but partially: it exposes the part of object's characteristics, which is relevant from the viewpoint selected, only. Thus, a system is supposed to support **holism**, but it is fictitiously holistic in its own traditional definition:

1. From the formal mathematical viewpoints, a system is an ordered **set**, hence holistic.

2. In its contents, a system embraces only a part of the really existing characteristics, hence it is not holistic; its scope is limited to the view-

point(s)/ aspect(s) selected by the **observer(s)/ manager(s)** of the topic in question. DST defines holism as a system (=ordered set) made of

- **Systemics** (= consideration of the global part of the given characteristics of the **event**, object or **process** under consideration, i.e. in a **synergy/synthesis**), and
- **Systematics** (= consideration of the detailed part of the characteristics of the event, object or process under consideration per parts with no synergies, i.e. analytically), and
- **Dialectics** (= consideration of **interdependencies** among mutually partly equal and partly different or even opposing **elements** of the object, event or process under consideration, and of processes, which are caused by these processes and cause the **transition** from the sum of systematic characteristics of the object, event or process under consideration to the systemic ones), and
- **Materialism** (= consideration of **reality** rather than self-bluffing about the characteristics of the event, object or process under consideration)

Holism normally includes consideration of the environment of the event, object or process under consideration, of course. This is called an open system concept. The open system concept, on DST terms, does not simply include environment from the specific selected viewpoint only, but also a system of all different viewpoints, which might be relevant, essential for achievement of a **requisite holism**."

0910

DIALECTICS¹⁾³⁾

It is significant to know that this word has been directly transposed from the greek **language**, where "dialektos" is a "lektos"(saying) from one to another, "dia-", i.e. a **con-versation**.

Its original and basically **semantic** and psychological **meaning** became much ignored or obscured, first by its use in philosophy, and later on by its association with marxism. It thus acquired in the mind of many an ideological taint, that should better remain clearly distinct from its prior meaning.

Because of its significance as a basic **relationship**, it should nevertheless be considered one of the foundational notions in **systemics**.

0911

DIALOGUE^{2) - 4)}

B. BANATHY (as well as other authors) has explored systemic ways to use dialogue, specially in **co-participative design processes**. He distinguishes between Generative and Strategic Dialogue.

Dialogue (Generative) is a "mode of social discourse... applied to generate a common **frame** of thinking, shared **meaning** and a collective world view in a **group**"

"In generative dialogue people may prefer a certain position, but they are willing to suspend it. They are willing to listen to others in order to understand the **meaning** of their position. They are able to face disagreement without confrontation and are willing to explore points of view that they do not subscribe to personally..."

"Generative dialogue is not a tool for addressing specific task-focused issues" (1996, p.39).

"Generative dialogue becomes the core **process** of transforming the **group** into a "community" (p.40).

Dialogue (Strategic) "focuses on specific issues and tasks in organizational and social systems settings" (p.40).

BANATHY advocates "Generative dialogue + Strategic dialogue as a combined **methodology for Design conversation**"

→ **Conversation; Language; Language competence; Learning**

0912

DICHOTOMY^{2) - 3)}

The division of a **class** of **objects** or concepts in two mutually exclusive and generally opposite groups.

From a systemic viewpoint, this fundamental feature of classical logic should be used with care. The cases wherein only two clearcut opposite aspects do exist are quite exceptional. Dichotomies tend to arbitrarily reduce **complexity** in issues to oversimplified oppositions. Another caveat is that **binary logic**, whose dichotomic nature is obvious, tends to institutionalize such oversimplifications into the computational **process**, that may act as a straightjacket for **model** building.

0913

DICTYOSTELIUM DISCOIDEUM^{1) - 4) - 5)}

A species of amoeba which can switch from independent individuals to structured **colonies**, and reciprocally, according to **environmental** conditions.

This amoeba is a member of the Acrasiales, which consist of eight species. It offers interesting insights in the way **colonies** and societies may become organized, as well as the deeper significance of **crowding effects**.

J.T. BONNER's **description** of this amoebas' **behavior** can be thus resumed: The **cycle** will start when spores are sown in a sufficiently moist and nutritious **environment** for the bacteria on which the amoebae feed. After a time these start to multiply by division, thus producing numerous independent individuals. However, when the food supply nears exhaustion and the amoebae **population** is dense, they stop to multiply (probably a **mass effect**

caused by very close **interactions**). Some become centers of **attraction** for others and they start to **aggregate**. After two to four hours of a wavelike **process**, all the amoebae will be collected in cell masses of different **sizes** and acquire communal and integrated properties and **behavior**. The agent of **aggregation** is acrasin (cyclical adenosine mono-phosphate – cAMP), i.e. a biochemical product which through successive pulses, in a growing situation of **crowding**, becomes locally more concentrated and attracts the amoebae (**Chemotaxis**). At the end of the **process**, most of the amoebae are part of a unique **group**. The final specialized **role** of individuals within the **colony** depends on the timing of their **integration**. The aggregated masses of amoebae show differentiated and variable collective **behavior**, according to **positions** within the **whole**, but start to migrate as a **whole** toward light and heat, even if **gradients** are very small. Finally, if adverse **environmental** conditions persist, the aggregated mass will stop moving and produce a stalk tipped by a small sphere, where spores become formed. These spores will disperse and restart the cycle when favorable conditions reappear. Individual and collective **behavior** are thus much closely related than commonly believed. It is noteworthy that the **production** of cAMP is started by one single individual, possibly one more strongly affected by starvation than any other. The **process** then propagates to more and more individuals, in a way reminiscent of crystallization in a solution starting from a small nucleus.

According to BONNER, a quite complex division of labor becomes apparent, depending of the position of the individuals within the **colony**, i.e. related to their **positional value** (1955, p.104-110).

I. PRIGOGINE and A. BABLOYANTZ did study this **phenomenon** in terms of **dissipative structuration** (1972).

For details about the biochemical aspects and **models**, see A. WINFREE (1980).

Similar propagation **processes** seem to be present under different guises in:

- **periodic dissipative structures** in unstable chemical solutions
- propagation of fires, **avalanches**, pandemics, etc... (**percolation**)
- optical-electrical reactive collective **behavior** in fish shoals
- acquisition of resistance to toxic agents in bacteria and insects
- panics and mass behavior in human societies

In all these cases this social-type propagation is a **cyclical phenomenon** progressing in a **wave-like** way from one or more foci.

It would be very interesting to discover in each case the self-generated and reproducing stimulating **agent**, corresponding to cAMP.

0914

DIFFERENCE³⁾

A variation in **perception**, **behavior** or thought triggered by one or various **bits** of **information**.

The perception of a difference starts with the **observation** of some specific **discontinuity** between the **background** and the **object**. Any system is in this way separated from its **background** by the **observer**, as the first step to its study.

As to the way this is done, in BATESON's words: "... a single difference may be the yes-or-no answer to a question of any degree of **complexity**, at any **level** of **abstraction**" (1973, p.244).

→ F. HEYLIGHEN's concept of "distinction".

In the mental sphere: "A bit of **information** is definable as a difference which makes a difference" (BATESON, *Ibid*).

Thus, differences are not necessarily new in the **objects** or **elements** themselves, nor in the in-between **space**: they affect **relations** as they are perceived.

Indeed, **observers** (i.e. **self-referential systems**, **organizationally closed**), in E. STEINER and L. REITER's words: "... can refer only to their own **states** and the difference between these **states**" (1989, p.232).

0915

DIFFERENCES³⁾

The **distinctions** that can be made between various **objects** or **concepts** at the same or various **levels** of **perception**.

As noted by KORZYBSKI and BATESON, there are many kinds of differences. We have thus a problem of management of different differences, i. e. of **categorization** and **hierarchization** of differences. Finding out **rules** of **transformations** that can be applied to **classes** of differences is essential not only to be able to think in an orderly and useful fashion, but altogether, as emphasized by KORZYBSKI in "Science and Sanity" to maintain our mental (and possibly physical) health (1950).

0916

DIFFERENCES (Hierarchies of)²⁾

G. BATESON considers that what the biologists call "**levels**" (of **complexity**), as for example J. MILLER's 8 **levels** in **living systems**, mark hierarchical differences.

He writes: "These are the hierarchies of units or *Gestalten*, in which each subunit is a **part** of the unit of next larger scope" and he adds "... this difference or **relationship** which I call 'part of' is such that certain differences in the **part** have **informational effect** upon the larger unit, and vice versa" (1973, p.433).

In this case too, it is our mind which discovers a relation, being in this case an **embedding** ordering.

0917

DIFFERENTIAL EQUATION: limits to its uses^{2) - 3)}

These very significant **limits** are thus stated by A. RAPOPORT: "Both the strength and the limitations of the mechanical outlook reside in the mathematical **methods** used in the construction of **mechanistic** theories. The fundamental tool of this **method** is the differential equation which is essentially a precise statement about how certain quantities and their **rates of change** are related" (1966, p.3).

After reminding the role of second derivatives (the **rates of change** of the **rates of change**), he notes that: "If several bodies are involved... their motions would then be described by a **system** of differential equations in which the **relations** between the positions and the accelerations are all interwoven by a **network** of **interdependencies**. Now if the differential equations comprising a system are **linear**, i. e., if the **variables** and their **rates of changes** appear at most in the first degree, the same general methods of solution apply regardless of how many equations are involved" (*Ibid*).

This unfortunately, is a very special case, to which most **complex phenomena** cannot be reduced, lest the **model** would eliminate the very nature of the modeled system.

In celestial mechanics, for example, perturbations calculus can be superposed on a basically dual system (The sun and the earth for example – a **two-body system**), but with three or more bodies of comparable mass, the differential equations cannot be solved anymore (POINCARÉ) and we enter the realm of **deterministic chaos**.

0918

DIFFERENTIATION^{1) - 2)}

A growing degree of **heterogeneity** in a system or in a filiation of systems.

M. DODDS states: "In the evolutionary **process**, two tendencies which characterise all systems, viz differentiation and **integration**, go hand in hand. Differentiation is **variety**-increasing **behavior** (**morphogenetic**), leaning towards increasing **complexity**, apparent **randomness**, **fragmentation**, **freedom**. **Integration** on the other hand, represents **pattern** and **order**... The two tendencies are complementary, not contradictory" (1994, p.1417).

According to J.L.L.E MOIGNE: "The formalization of differentiation **processes** seems still uncompleted. Two types of **phenomena** may be distinguished: the ones - **morphostatic** - evolve by extension, by **regulation** or even by equilibration; the others - **morphogenetic** - evolve by **reproduction**, by **bifurcation** or by mutation" (1977, p.191).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The first type results from the progressive expression of the virtual characters of the system during the **process** of its **development**, characters that became inscribed in it at the moment of its **autogenesis**. In this case, the system undergo **transformations**, but maintains its **identity**.

The second type of differentiation leads to the **emergence** of systems endowed with a superior degree of **organization**. Evolutive differentiation is aided by **isolation** of different **groups**, but impaired by recombination: this seems also to be sometimes true for technical and cultural variation. This is not anymore mere **transformation**: it becomes **evolution**. It would be quite useful to coin different terms to express these two quite different **concepts** of differentiation.

Differentiation is, by its nature, **irreversible**, as it leads to increased **complexity** coupled with an increased **level** of **entropy** production.

0919

DIFFUSION²⁾

Progressive expansion of some **class** of **elements** from a high concentration **zone** to adjacent available and suitable **space** in their **environment**.

In many cases, diffusion leads to the shaping of dependent or independent new **clusters** or **colonies** of the **elements**. Diffusion produces a decrease of the local concentrations of the **elements**, but can be followed by a heightened **reproduction rate** of the same.

0920

DIFFUSION – COALESCENCE²⁾

A **process** through which a great number of scattered **elements** of the same kind tend to concentrate into tightening **clusters**.

Such **processes** can be observed in physics, but seem also to happen in some kinds of **living systems** as for example in *Dictyostelium discoideum*, in migratory locusts and even possibly in human **congeries**, like the modern megalopolis.

0921

DIFFUSION-LIMITED AGGREGATION²⁾

A mathematical model of numerous **processes** of patterned **growth** in systems.

(After M. BUCHANAN, New Scientist "Inside Science", Nr 121, p.4, 1999)

DLA is characterizing a great **variety** of **reaction-diffusion systems**, in which "**patterns** result from a basic **competition** between a **set** of forces that tends to amplify differences, and another that tends to dampen them out". (Ibid.)

An excellent example is the **Belousov-Zhabotinskii reaction** in chemistry..

→ **Dissipative structure**

0922

DIFFUSION-REACTION PROCESSES²⁾

A process that produces successions of receptive, active and quiescent **states** in **elements** (within an expanding diffusion-reaction process)

→ **Cyclic order**

0923

DIGITAL CODING⁵⁾

A **method** of coding using only two precisely defined **signs** indicating presence or absence, 1 and 0.

The basic logical **concept** of digital coding is **Boolean Algebra**. It is of universal use in so-called digital computers because it allows for the **sequential** treatment in a very short time of enormous quantities of **data** and instructions, previously translated into this **binary language**.

0924

DIGITAL COMPUTING⁵⁾

Computing based on the use of a **code** consisting of two **signs** or positions only.

Digitalization is the base of our actual computers, in contrast to **analogue** computing which uses continuous **signals** of variable intensity.

A. G. BARTO states: "Digital computing and **discrete models** are influencing our conception of real world systems and the role classical mathematics methods are to play in **modelling** them..." (1978, p.163). (See "**Dichotomy**").

Physicists, chemists, engineers, etc. accustomed to the successful use of **differential equations** "... have strongly developed intuitions in which continua and **rates of change** are powerful conceptual primitives. Those whose intuition has developed more directly under the influence of digital computing, on the other hand, find it very natural to think in terms of such concepts as **algorithms**, **data structures** and **automata**. In many applications of these **discrete concepts**, the availability of theoretical results is replaced by the computational power of digital computers" (Ibid).

This is really a very basic conceptual evolution, since, as noted by BARTO, "...actual digital computers can manipulate only finite **sets**" (p.164) of **discrete data**, while classical mathematics uses extensively the **continuity** and infinity concepts.

These two approaches are complementary rather than opposed to each other, but a clear **understanding** of their different nature is needed. See hereafter for more comments.

0925

DIGITAL SIGNAL⁵⁾

A signal coded in a **binary** way

The digital signal corresponds to **binary** or **Boolean** logic, i.e. a **coding** system wherein only two opposite positions are admitted as, for example, yes/no; or true/false, which can be represented by 1/0 or pulse/no pulse.

Digital signals imply necessarily a **discrete coding**, in opposition to continuous **representation**.

0926

DIGITALIZATION^{2) - 5)}

A **method** of **data processing** through which **information** from outside of the system, complex and **continuous**, is "cut" into **informations discrete** in **time** and **space** (J.C. TABARY, 1989, p.278).

J.C. TABARY writes: "The characteristics of the **receivers** do organize the "carving", not so the peculiarities of outside **information**" (p.278).

This is a most general consequence of the "**All or nothing**" principle.

0927

DIMENSION (Critical)¹⁾

Dimension below or beyond which a system is not anymore **viable**.

Any system corresponding to some defined type is unavoidably inscribed within **survival** conditions which impose to it a minimal dimension below which it could not have all of the needed **structures** and **functions**. Equally, beyond some maximal dimension the needs of the **communications**, **regulation** and **control subsystems** cannot anymore be satisfied, because sufficient **resources** are not available or cannot be transported. In both cases the resulting malfunctions lead to the demise of the system.

0928

DIMENSIONAL DOMAIN^{1) - 2)}

The **region** of **space-time** occupied by a system.

This term was created by A. ANGYAL (1941, in F.E. EMERY, Ed., 1969, p.21).

The dimensional domain is similar to a **topological space**, extended over the **time** dimension. Its characteristics are defined by the system within and it thus becomes differentiated from its **environment**.

According to ANGYAL: The dimensional domain is intimately involved in the formation of systems" (p.21).

It becomes defined through the **autogenesis process**, but it may grow and undergo internal **transformations**, within defined **limits**. The dimensional domain contains the systems **structure**. In ANGYAL's words: "A system is a **distribution** of the members in a dimensional domain" (p.25).

J.W. SUTHERLAND distinguished in a somewhat different – and more precise – sense:

- "the ecological dimension of the system which encompasses its "without";
- the domain dimension, which is its "within";
- the dynamic dimension "which is used to house any structural or functional **changes** which might occur between successive snapshots" (1974, p.131).

In this encyclopedia the term "**invironment**" is proposed for the domain dimension "within".

0929

DIMENSIONS (Physical and Mathematical)²⁾

G. MAYER-KRESS writes: "A very important **distinction** between the mathematical and the physical concepts of dimension is that mathematically the dimension is invariant under smooth **transformations** like deformations and **changes** of the coordinate system. If we take a ball of dough and roll it out to form a one micrometer thick pancake, then in a mathematical sense these are both three-dimensional **objects**. From a physicist's point of view, however, it might be important that the pancake can be treated as a two dimensional **object**. This apparent **change** of the dominant dimension plays a significant role in **dynamical systems** and **fractal chaos**.

"Dimensional arguments in physics have let to profound discoveries in, for example, turbulence, in **phase transition** theory and elementary particle physics, as well as in developing **renormalization** theory" (1988, p.357).

Of course, physical **fractalization** ad infinitum is impossible, because there are **changes** in the *nature* of the **elements**. **Parts** of a **complex system** may be **fractal**, but each **subpart** is generally itself another **complex system**, which in turn can be only partly **fractal**. At each **level**, the **parts** are of different kinds, for example **cells**, **molecules**, **atoms**, etc.

0930

DIMINISHING RETURNS (Law of) to scale^{1) - 2)}

K. BOULDING, having explained the relation between **growth** and structuration, explains why "the **size** of the **structure** itself is limited by its inability to compensate for the non-proportional **changes**" which is "the basic principle which underlies the law of eventually diminishing returns to scale".

Indeed, more and more **communications**, **regulation** and **control structures** are needed as the system grows, in order to maintain its **coherence**. These **functions** and **structures**, while essential for the transportation and allotment of **resources**, are not directly productive. Quite the contrary, they use up **resources** which are diverted from the productive **functions**.

BOULDING concludes that: "...these structural limitations bring the **growth** of the **organization** to an end" (1956, p.66-75).

Moreover, the excess of **complexity**, at least in human **organizations**, leads to a certain internal disconnection and the appearance of **subsystems** which in some cases, end up in an almost parasitical situation (for example authoritarian, uncontrollable and sterilizing bureaucracies).

H. ODUM sees that the law applies in **complex systems**: "... where the several **flows** of necessary **inputs** have a multiplicative **action** on the **input flow**. As any one factor is increased, it gradually passes through its limiting **range** to a plateau as other members of the **flow** become limiting" (1971, p.187).

As an example, D. PIMENTEL applied the **concept** to **energy** subsidized agriculture (not always direct, clearly visible, nor perceived) and shown its final **limits** (1977).

0931

DIPOLE²⁾

"The simple **black box** which has a single **input** terminal and also has a single **output** terminal" (M. BUNGE, 1979, p.254).

This a specifically cybernetic definition of a dipole representing "the simplest complete **black box** (which) is sensitive to **stimuli** of just one kind and accepts just one **stimulus** at a time... It acts just in one fashion on its **environment** and performs one **action** at a time... Any more complex **black box** is called a **multipole**" (Ibid).

0932

DIRECTIONALITY²⁾

Dynamic property of the logical **organization** of a system such as any **change** seems to aim at a **goal** in the future (in a **homeostatic system**, in a functioning **autopoietic system**, in a **tropism**, in an intention or objective) (adapted from E. SCHWARZ, 1993, P. 13)

SCHWARZ adds: "One could be tempted to oppose a causal system (whose present state is caused by its past) to a **teleonomic** system (whose present **state** seems to be conditioned by a goal). This would be an error, since the teleonomic property is itself causal, i.e. the result of the history of the teleonomic system" (Ibid)

So much for the science-fiction's time paradoxes!

0933

DIRECTIVE CORRELATION

→ **Correlation (Directive)**

0934

DISAGGREGATION⁵⁾

A higher **resolution level** in a **model**, that aims at showing more clearly **variables** considered as more elemental.

D. MEADOWS et al. write, referring themselves to the supposed practical benefits of disaggregation: "...every **modelling** effort is subject to severe **constraints** of **time** and **resources**. It is never possible (or desirable) to include everything that analysts – or others – think may be desirable. As a **model** becomes more detailed, **data** requirements, mathematical problems and overall **complexity** increase at a rapid rate. Detail can become a heavy burden when the time comes to debug the computer **program** or write documentation. Sometimes the decision to use a higher **level** of disaggregation results in excluding whole sectors or, perhaps limiting the time available for **validation**, **sensitivity** analysis, documentation or even actual use of the **model** to calculate results. It can also make the running of the **model** very expensive" (1982, p.101-2).

0935

DISASTERS: A systemic view¹⁾

Most disasters, in particular those concocted by men, have complex **causes**, are complex when they succeed and have complex consequences. They are thus a typical object for systemic research.

Complexity of **causes** is of two different orders:

- Numerous concurrent **causes** are generally necessary to bring about the disaster. The **understanding** of their progressive **interactions** is of paramount importance for **prediction**, reaction and mending. One specific **cause** must be considered with special care: the **trigger cause**, which also has its own **causes** (no **trigger**, no disaster...).
- **Causes** are connected with **processes** that turn **critical** at some **time**. However, not all of these **processes** are at the same **time scale**. It is of paramount importance to distinguish between the slow **accumulating causes**, at times on a secular or multisecular **process scale** and, at times on a much **shorter term**.

Complexity in itself is the result of multiple **interactions** among **processes**, some very basic, some other circumstantial... and many of them hidden or at least not readily visible. Only a good **knowledge** of these **interactions** can draw the attention to potential **risks** at specific moments.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

In many cases, **side-effects** of human **action** are also ignored, as research on physical **causes** generally shadows psychological, social, political, economic and even cultural ones. This ignorance is in itself a **cause** of disasters.

In synthesis, research on disasters, past or in the making, must be systemic.

→ **Cindynics**

0936

DISCINYM⁵⁾

"A word used to describe the specific case of an **isomorphic process** realized on one **scale** of reality, but which **maps** with many other cases, on other **scales**" (L. TRONCALE, 1985, p.76).

Since this neologism was proposed, it did not entered in wide use. TRONCALE gives the following example of a situation that would justify its creation: "... the use of "**homeostasis**" in anatomy (**note**: or physiology?) for the more general concept of "**dynamic equilibrium**". These diverse *disci*-plinary names for the same **process** or **structure** (**isomorph**) are *synonyms* for the **general systems** term" (Ibid).

0937

DISCIPLINARITY (Inter-, multi-, trans-) ¹⁾

R.L. ACKOFF states: "Nature is not disciplinary. The **phenomena** and the problems which nature presents to us are not divisible into disciplinary **classes**. We impose scientific disciplines on nature; it does not impose them on us. Some of the **questions** that we ask of nature – in contrast to the problems it presents to us – can be classified as physical, chemical, biological, and so on; but not the **phenomena** themselves... For example automobile accidents can be viewed at least as physical, biological, psychological, sociological, and economic **phenomena**. To study them in any one of these ways is to exclude **variables** relevant from other points of view" (1964, p.54).

This is of course not an anti-disciplinarian stand, but merely a caveat about **reductionist** blinders.

G. KLIR observes: "As a result of arguments pursued by **systems science** for decades, scientist are now becoming, in general, more sensitive to the limitations of their own disciplines. They tend to be considerably more aware now than a few decades ago that significant real-world **problems** involve almost always aspects that transcend disciplinary **boundaries**" (1993, p.51).

The subject of **interrelations** in-between specialized scientific disciplines is quite a difficult one. While the more generic term of cross-disciplinarity is frequently used, we propose the following distinctions in order to avoid the **semantic** muddle and the practical confusion which characterizes it.

Interdisciplinarity: indicates a specific **inter-relation** between two disciplines. Some examples could be: biochemistry, agrobiolgy, paleobotanics, astrophysics or astrodynamics and, in a somewhat extended sense economic history, population genetics or the comparative study of natural and artificial **neural nets**.

Multidisciplinarity: relates to a type of collective study of some complex project, in which specialists in numerous different fields must collaborate. Some examples are: the participation of economists, financiers, lawyers, engineers, geologists, agronomists, hydrologists, etc. into the planning of a great hydropower dam and irrigation scheme; or the global study of climate by meteorologists, oceanographers, physicists, chemists, vulcanologists, botanists, ecologists, etc.

Transdisciplinary: qualifies a set of general **methodologies** and **modelization** tools better adapted to study the numerous **interactions** and **feedbacks** within **complex systems**, as well as their significant exchanges with their specific **environment**. It applies to the same type of projects or **situations** studied by multidisciplinary endeavors, but it contributes tools for reciprocal **understanding**, discovery of hitherto unperceived **interfaces** and integrating synthesis

Interdisciplinarity: does not per se present many difficulties. It implies generally the bridging of two disciplines because one needs of the other or one brings new insights to the other. The astrophysicist, for example interpretes astronomical discoveries in physical terms and normally has an excellent **knowledge** of both fields and of the mathematics needed as lingua franca.

Multidisciplinarity: on the contrary brings along quite a number of misunderstandings. It reflects the ever growing need for collaboration among many (and very diverse) disciplinary specialists for the **planning** or the **management** of **complex systems**. Unfortunately, most of multidisciplinary meetings – especially those which must produce some critical **decisions** about practical projects – lead only to confusing misunderstandings and quite frequently to awful "**messes**" (in R. ACKOFF's words) and costly man-made **disasters**.

Transdisciplinarity implies:

1. The existence of a **meta-level** of **models** and **concepts**, leading to an integrated **synthesis**, constructed and understandable by all the **stakeholders** of the system under study (even those whose opinion has not been asked for).
2. The existence of a common **meta-language**, based on **isomorphies** and useful to convey synthetic **perception** of complex **wholes** and intricate **meta-models**.

No biologist will become an engineer, nor a geographer an economist, but they may thus reach a better mutual **understanding**, learn to ask "good questions" and to provide answers, meaningful not only for themselves.

General systemic and cybernetic concepts are preferred tools for transdisciplinarity

→ **the three corresponding specific headings.**

0938

DISCONNECTED COMPONENT ^{1) – 2)}

"A component which is only part of a system incidentally or is included only because it is defined so" (T.F.H. ALLEN & T.B. STARR, 1982, p.266).

ALLEN and STARR express: "There may be weak **interactions** between a disconnected component and other components of the system, but these are incidental to what is recognized as the normal functioning of the system and are not involved in the main lines of **communication** in system functioning" (Ibid).

An example could be the introduction of some secondary or temporary cultivar in an excessively **homogeneous** one in order to reduce pests propagation.

0939

DISCONTINUITY

→ **Continuous-discontinuous**

0940

DISCRETE or CONTINUOUS ? ^{1) – 2) – 3)}

W.S. IRVINE, in a review of D. GREENSPAN's "Discrete **Models**", writes: "Nature seems to abhor both a vacuum and a **linear response**". This is a very serious matter, since most of our **models** are **linear**, being based on the famous... **et ceteris paribus**, which in most cases is merely a comforting delusion of the **modeller**.

IRVINE observes: "Calculus evolved to handle a continuous system of equations, resulting from a series of discrete **observations**. Calculus provides continuous solutions that must be matched to discrete **observations** for verification. We tend to forget that calculus is a compromise at best, not an act of faith. When the equation system generated by the natural **phenomena** is too complex for calculus to provide analytic solutions, we often make assumptions and linearize until one can be found" (1978, p.131).

An imprudent use of this **method** may lead us to ignore, or worse, disclaim some seemingly aberrant **values** that could appear within an apparently **linear function**. It also may lead us to believe, if not in some fallacies of infinity, at least implicitly in that other and more subtle fallacy of accelerated and unchecked **growth**. This is surely one of our most questionable contemporary postulates.

A.G. BARTO writes on this same topic: "... a discrete **model**... might be formalized as a set of difference equations or as an **automaton**" (1978, p.164). **Automata**, indeed, show a discrete **behavior in time**. In contrast, "The term **continuous model** will refer to a system whose **time** base is the uncountably infinite set of real numbers".

Still: "The domain of a discrete **function**... is a **set** of integers. The **function** is not defined for real numbers between the integers" (Ibid., p.169).

We face thus a methodological **ambiguity**: our **selection** of a continuous or a discrete **model** always implies a basic definition about the **structure of space** and **time**. Such a definition is necessarily an unverifiable postulate.

0941

DISCRIMINATION ²⁾ - ³⁾

The act of drawing **distinctions**.

Discrimination implies separation from a heretofore indistinct physical, **conceptual** or **semantic environment**, through a newly acquired **perception** of a **difference**. It leads for instance to the identification (R.W. GERARD's "entitiation") of a system.

Perceptual discrimination is limited by physical and physiological conditions. The first ones are defined by basic physical constants (for example the quantum of **action**) and the second ones by the capacity of our senses to register specific **levels of action** (for instance sounds, but not ultrasounds).

0942

DISERGY ²⁾

A combination of **effects** that produces unsustainable or destructive results.

This is the contrary of **synergy**.

The possibility of disergies should be seriously researched and carefully watched, particularly in **human systems**, which are frequently managed in irreflexive and imprudent ways.

This neologism has been introduced by Rafael RODRIGUEZ DELGADO (1997, p.72) in a slightly different form ("Disenergy"). "Disergy" has been adapted here as more consonant with "Synergy".

0943

DISFUNCTION ¹⁾ - ²⁾

Uncorrect or impaired functioning of a **process** corresponding to a **subsystem** in a system.

Disfunction may be caused by **stress** or **wear**, which in turn result of **overload**, or on the contrary, insufficient **inputs** or **communication** failure.

Disfunction passes easily unnoticed in its initial **phases**, a potentially very dangerous **situation**. A frequent monitoring of **critical processes** in systems is needed in order to avoid sudden and unforeseen **disasters**.

0944

DISINTEGRATION ¹⁾ - ²⁾

A destructive **process** which breaks up the necessary **interactions** among the **elements** or **parts** of a system.

The disintegration **process** destroys the system by reducing it to an uncoordinated heap of disconnected **elements** and making it disappear as a significant **whole**. The **elements** do recuperate their total **independence** or, at least, even when they remain close to each other, are not anymore functionally **cooperative**. An example is the wreck of a sunken ship.

Disintegration results from the inability of some essential **part** of the system, generally some important **control system**, to perform its specific task. This may result from some irreversible damage or from the interruption of a basic **flow of inputs** or **outputs**. Some authors use the term "segregation" in the same meaning as disintegration (B. BANATHY, 1973, p.88).

When basic processes become impaired, the system endures growing **stress** that it becomes finally unable to counteract and loses any possibility to resist external **perturbations**. Most of its elements then disperse more or less randomly in the **environment**.

However, in some cases, some **structures** may resist destruction for a long, or even very long **time**: examples are animal and vegetal fossils, skeletons, ruined historical buildings and even so called dead **languages** as egypatian hieroglyphic language or sumerian cuneiform

→ Ageing; Aura; Autopoiesis; Decay; Entropy production (Minimum); General adaptation syndrome; Inenvironment

0945

DISJUNCTION PRINCIPLE (D.P.) ¹⁾²⁾

Global **determinism** is not possible because of the non-instantaneous character of **interrelations** propagations.

This derives in fact from **relativity** theory and the multiplicity of **simultaneous events** in different places.

It explains why Laplace in his famous enunciation of universal and absolute determinism (R. PASSET, p. 33) must introduce an universal and omniscient intelligence.

Of course, such an intelligence does not exist in any known living being of the past or the present.

It is however to be noted that the very disjunction principle is in itself...disjoined

In effect the "coefficient of disjunction" (i.e. the time needed for the propagation of **effects** between various **entities**) is different in all cases. Andromeda galaxy is more disjoined from us than the sun and the sun more disjoined than the moon.

The D.P. is also at the root of **chaotic determinism** and has basically a **time dimension**.

As such it must have some **connection** with **thermodynamics**.

This is a mere preliminar exploration of the subject whose consequences could be far reaching (and possibly very controversial)

0946

DISORDER ¹⁾ - ²⁾

A general **state** of lack of **coordination** between **elements**.

It would possibly be better to create a neologism for such a **state**, for example "unorder", because in common **language**, disorder really means "seriously altered order"

It is obviously in such a dubious way that R. FIVAZ understands disorder when he defines it as an "arbitrary arrangement in **time**, **space**, velocity or other dimension of positions of **elements** in a system: the arrangement is such that positions in any **part** of the system cannot be predicted from the **knowledge** of positions in any other **part**" (1991, p.31).

It seems however clear that "arrangement" and "disorder" are compatible terms only if disorder is not total.

In accordance with **thermodynamic** laws, disorder means "a completely featureless **distribution of elements**", which corresponds to the **state** of maximum **entropy**, and **random distribution** and movements of the **elements**.

This is a generally **final** situation and, in case of systems the "end of the road". As St. BEER once said: "Death is **equifinal**".

As in a disordered **state**, no **constraints** exist, or in other terms no **algorithmic compression** is possible, the quantity of **information** that would be needed to describe it is maximum. This is the reason (questioned by some authors) why **information** is many times quoted as corresponding with so-called "**negentropy**".

Chaos theory introduces the **understanding** of a different kind of disorder: the general **unpredictability** resulting from complex **dynamics**.

0947

DISPERSAL ¹⁾ - ⁴⁾

The capacity of **elements** present in an optimal microsite to migrate to other ones.

This is an important feature for the reconstitution of **ecosystems** that have been affected by a **disturbance**. It may as well be important for **human systems** partially destroyed by some **disaster**. In France, for instance, after the Black Death pandemics (1347-1352), artisans were brought over from Italy in order to reimplant some disappeared specialized trades.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

0948

DISPERSAL RATE ²⁾

The rate of **propagation** in **space** of some type of **elements**.

Dispersal rates depend on:

- specific characteristics of the **elements** which are favorable or unfavorable to **dispersion**
- the general conditions of the **environment**, which can be: a) different in different directions (**anisotropy**)
- stable or unstable in **time**, as for example in case of **cyclical** or irregular climatic change.

0949

DISPERSION ^{1) - 2)}

Capacity of a **complex system** to detect, either simultaneously or in an alternative way, some **inputs** or **stimuli**, by way of different perceptive and transmissive **subsystems**.

ASHBY, who introduced this notion, gives the following examples:

"The point to point **representation** of the retina on the visual cortex, for instance ensures that the dispersion achieved in the retina will at least not be lost (1960, p.180).

"...if a beam of radiation of wave-length $0,5\mu$ is directed to the face, the eye will be stimulated, but not the skin; so the optic nerve will be excited, but not the trigeminal. But if the wave-length is increased beyond $0,8\mu$, the excitation changes from the optic nerve to the trigeminal (p.179).

In other words, dispersion enhances adaptive polyvalence.

0950

DISPERSION (Controlled) ²⁾

S. BEER introduced in 1966 a different **concept** of dispersion: the progressive branching of some **process** in the **time** dimension, with the corresponding variable **interactions** in-between different effects of the initial **cause** or causes.

He described graphically his **model** through a **tree** arranged along the **time** dimension, which he calls "dispersing stochastic network" (1968, p.180).

In the light of the **deterministic chaos model**, "stochastic" takes on a deeper **meaning** since it could now be added that any **network** flowing through **time** is bound to be dispersive, but within the **limits** of **coherence** proper to the **network**, according to its **interaction rules**. This makes BEER's model still more insightful.

→ "Convergence (Controlled)".

0951

DISRUPTION ¹⁾

The breaking asunder of any system by the destruction of one or various of its regulating devices.

Regulators are **circuits**, based on **feedbacks** and composed of two or various interconnected **arcs**. Cutting one of these **arcs**, or even only mishandle it, may disorganize or destroy the whole system.

This is frequently the case when mere consequences are confused for **causes** in **complex systems**. A good example has been the HWO campaign to eradicate paludism through insecticide spraying against anopheles, and synthetic drugs use against the plasmodium, without taking in account that paludism is part of very complex ecological systems, including waters, plants, animals and human settlements of great **variety**. Moreover, the **co-evolutive** ability and **adaptiveness** of the intervening species also were ignored. As a global result, paludism is presently out of **control** in expanding zones.

In G. BATESON's words: "Characteristically, **errors** occur wherever the altered causal chain is part of some large or small **circuit structure** of a system. And the remainder of our technology (of which medical science is only a part) bids fair to disrupt the rest of our **ecology**" (1973, p.119).

The disruption problem is a typical result of partialization in the **management** of systems of any kinds.

0952

DISSIPATION ^{1) - 2)}

The **rate** at which **entropy** is produced by an **energy** fed system.

Dissipation is concomitant with the existence of **nonequilibrium** conditions within **concrete systems**.

Energy can be dissipated in three different ways:

1) "by microscopic **interactions** between entities in a virtually **homogeneous** or "incoherent" **field**" (F. ROBB, 1990, p. 138). This type of dissipation is dealt with by the purely **abstract model** of **entropy growth** in **isolated systems** (i.e. deprived of **inputs**) proposed by classical **thermodynamics**.

2) According to PRIGOGINE's theorem of **minimum entropy production** in **homeostatic systems** at a given **level of complexity** and in their **state** of maturity. This is thus expressed by M. CEREJIDO: "The system tends toward **structures** which will permit it to maintain its **entropy production** at the lowest possible **level** (until it reaches) more equilibrated **structures** with the minimum dissipation" (1978, p.97). This is L. ONSAGER's *Minimum Dissipation Principle*, according to which replication of systemic **structures** has a lower **entropy cost**

that creation of new **structures** by dissipation (1931, p.405-26). This is consonant with the acquisition of **stability** by **autopoietic systems** as well as with BÉNARD's **dissipative structuration**, once the system stabilizes, and **structures** are only **maintained** through a minimum dissipation **rate**, or least dissipation, regulating the **energy flow** to a minimum compatible with the system's **survival**.

This kind of dissipation is proper to systems submitted to **wear**, and end by final **break-down** (see "eigen time").

3) "by the **emergence** of a new higher **order entity**, a "coherent" **field** which dissipates even more **energy** (by increasing the area of the dissipative surface)" (F. ROBB, 1990, p.138). R.N. ADAMS in turn, writes: "The dissipation of expanding systems increases the amounts and varieties of **energy** forms being incorporated and thus also the low- quality **energy** and **waste** material eliminated or marginalized because it cannot be processed inside the **structure**. Hence, dissipation not only creates areas of **control** (certainly within the **structure**, and sometimes outside it) but also creates areas beyond **control**... Thus the act of dissipation creates in the **environment** new dynamic factors in natural selection" (1988, p.136).

In the second as well as in the third case, **dissipative structures** must sustain themselves in a dynamic way by permanently obtaining from a specific **environment** the needed **energy inputs**. As observed by R.N. ADAMS: "For them construction and destruction are simultaneous. In **organisms**, old **cells** dissipate while new **cells** are formed; in societies, people die and are replaced by new people who are taught by the old" (p.60).

Systemic **complexity** is proportional to **energy** dissipation. Or, in other words, systems are **entropy** accelerators and the more complex ones are the strongest accelerators.

Of course, any system depends on its **environment** to obtain the **energy** it needs for dissipation and, *globally*, the **2nd. law of thermodynamics** is respected, even if locally, within the system, a more complex degree of **organization** appears.

As to the ultimate nature of dissipation, it seems to be some sort of general cosmic **dynamics**. The rumanian physicist S. LUPASCO (1900-1988) who developed his views in France, sees this cosmic dynamics as reflected into the opposition between the **2nd**. Principle of **Thermodynamics** (which prescribes the unilateral and irreversible degradation of the quality of **energy**) and PAULI's **Exclusion Principle**, according to which any two particles can never have their four basic quantum numbers identical (1974). This prescribes obviously a very basic condition for the **organization** of the material world, that LUPASCO describes as "energetic antagonism".

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

Such an antagonism is clearly visible in the genesis of material **forms** (D'Arcy THOMPSON, 1916, Ch. Laville, 1950)

→ **Entropy production** (Theorem of Minimum); **Fields** (Interactions between); **Form and Force**; **Morphogenetic field**; **Structure** (Dissipative); **Symmetry breaking**; **Vortex**

0953

DISSIPATIVE STRUCTURE

→ **Structure** (Dissipative)

0954

DISSOLUTION OF A SYSTEM^{1) - 2)}

Ch. SMITH resumes E. JANTSCH's synthesis about a system's dissolution in conditions of **turbulence**. Associated conditions and **processes** are as follows:

"a) **Initial conditions of disequilibrium** – through a system's opening to internal or external forces of **turbulence**. Forces moving a system toward **disequilibrium** must be sufficiently intense or be stepped up to a degree that they act to push the system out of its **equilibrium** maintaining or stabilizing **parameters**.

"b) **Symmetry breaking** – involving a system's breaking down of its **structures** and **processes** – (must reach) to an extent that sufficient **degrees of freedom** become available as a capacity within which new **structures** may be formed" (1986, p.206).

Of course, many systems are utterly destroyed by **turbulence**, never getting any chance to reach a higher **level of organization** by **dissipative structuration**.

In these cases, their **elements** are set free and may become **parts** of new systems. This has been the case, for example, of members of archaic tribes who individually survive the destruction of their society and are incorporated at least biologically in another culture, carrying over with them some genetic and cultural traits.

0955

DISSYMMETRY^{1) - 2)}

Uneven **distribution of energy** or **matter** in **space** and in **time**.

This notion was introduced by L. PASTEUR (dissymmetry of tartaric acid crystals) and has taken a growingly general character. It seems to be related to **dissipative structuration** and **emergence of complexity** in systems and, consequently with **thermodynamics of irreversible systems**.

A dissymmetric **concept** of the **effects of entropy** is now also basic in H. SABELLI's **process theory**, according to which all **processes** and **concepts** imply two opposite **dynamics** or **forms**.

0956

DISTANCE (Critical)^{1) - 2)}

The distance at which formerly isolated **elements** start to interact or formerly interconnected ones become totally independent from each other.

(Also called "Correlation distance, or length")

This intriguing notion is undoubtedly present from the subnuclear **level** up to the most global social one.

Critical distances depend on "forces" acting through **space** and **time**, in ways generally quite difficult to explain. Moreover, there are **interaction thresholds**, specific for every kind of **interactions**, be they subnuclear weak forces or human **communication nets**.

Crowding (or scattering) seems to be always the **trigger** factor, but this concept is nearly tautological with the "critical distance" one.

In any case, no **complex system** may appear, nor subsist when distances between **elements** do not allow for more or less frequent **interactions**.

The concept evokes very basic questions about the nature of **space** and **time** and their relative **meaning**.

0957

DISTINCTION³⁾

A relation between **phenomena** which is conserved in a bijective way even if the **phenomena** themselves change during the **process**.

This **concept** has been discussed by J.A. GOGUEN and F. VARELA who state: "A distinction splits the world into two parts, "That" and "This", or "environment" or "system", or "us" and "them", etc. One of the most fundamental of all human activities is the making of distinctions. Certainly, it is the most fundamental act of systems theory, the very act of defining the system presently of interest, of distinguishing it from its **environment**. Distinctions coexist with **purposes**". (1967, p.32) The corresponding logical **model** is based on SPENCER BROWN's distinction algebra (1969)

It is also useful in order to differentiate causal and stochastic **processes**, as well as reversible (retrodictable) or **irreversible** (and more or less **predictable**) ones.

HEYLIGHEN states: "To be meaningful, a distinction must have a minimal **stability** or **invariance** (i.e. during (certain) dynamical evolutions it must either remain constant or be mapped on another distinction)" (1989, p.382)

"A distinction is constructed by the **observer** in **interaction** with the system. As such, a distinction is always to a certain degree subjective, depending on the **goal** the **observer** has in mind while modeling the system, but is not arbitrary, because not all distinctions will allow the **observer** to find **coherence** between the different **observations** performed on the system. Since all **phenomena** in the universe are

by definition different, the number of potential distinctions is infinite. A **representation** of (part of) the universe is necessarily finite, and, hence, the number of distinctions an **observer** will make will be infinitely smaller than the total number of distinctions he or she could make" (1990a, p.427)

The preceding comment is specially significant for human sciences.

In effect, any psychological or social distinction- much more than distinctions in hard sciences- is always made "in situ", i.e. in some specific observing way allowed to the **observer** by his/her culture (D. BAECKER, on LUHMANN's "sociological enlightenment", 1996, p. 5).

It is thus very important to try to solve what BAECKER calls the "problem of **latency**", i.e. find ways to discover (distinguish!) "the manifest from the latent and thus "double" the world in two versions, a visible one and a hidden one" (Ibid, p. 8)

According to G. SPENCER BROWN (1979) "... a distinction is drawn by arranging a **boundary** which separates sides so that a point on one side cannot reach the other side without crossing the boundary"

For a critical study of SPENCER BROWN's concept, see R. GLANVILLE "Beyond the boundaries" in ERICSON, R. (Ed), 1979

E. SCHWARZ made however the following- and quite disquieting- comment: "Distinction...- which is a necessary prerequisite to making pertinent scientific **models** of the world, has led to the radical separation of the **objects** (and of the forces) found in the **mechanistic approach**; the exaggeration of the **separability** of the mechanistic approach; the exaggeration of the separability of things prevents us to be aware of the dense **network** of **relations** between the **events** of the sensible world. Many of the contemporary concrete problems of our technological society (ecological, economical, social, etc) are due to the neglect of the **web of interconnections** between the **phenomena**".

He adds: "It seems to us that the thought of David BOHM is a crucial step toward a reconciliation between the necessity to make distinctions in order to recognize the **configurations** of the world around us, and the need to be conscious that we are a non-separable part of the world" (1999, p. 138-139)

→ **Separability; Wholeness**

0958

DISTINCTION (Primary)²³⁾

The most elemental distinction that can be made. D. HERBST writes: "When a distinction is made, a **boundary** comes into being together with the inside and the outside of a **form**. What is generated in this way is a triadic co-genetic unit consisting of the inside, the outside and the distinction made, which is represented by

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

the boundary. At this stage, we have nothing more than a form in an empty **space**"(1993, p. 29)

Examples are a line (or a circle) in an empty two-dimensional surface, or plane.

Herbst adds: "In its most general form, what has become generated...is a unit consisting of not less than three **elements**"(Ibid)

This is in fact the basic **triadic** unit, related in different ways to Ch.S. PEIRCE's "thirdness" and to SPENCER- BROWN's **laws of form**.

Any distinction is also an **operator** in the meaning developed by R. VALLEE (1995)

→ **Dyad; Network; Topology; Triad; Triadic relation; Triadicity**

0959

DISTINCTIONS (Cinematics of) ³⁾

According to F. HEYLIGHEN, "The cinematics of distinctions can be viewed as a general **description** of possible **processes** involving distinctions. For a given type of distinction there are four types of **processes**:

"1. Conservation of the distinction: This can be modeled by a one-to-one, **bijective function**, corresponding to a **process** reversible and **predictable**" (1990a, p.427).

The author probably means that past **states** of the **process** confirm the distinctions.

"2. Destruction of distinctions, but without creation of new ones: This can be modeled by a many-to-one, surjective **function**, corresponding to a **process** **predictable**, but **irreversible**

"3. Creation of new distinctions, together with maintenance of the existing ones: This can be modeled by a one-to-many relation (not a **function**) corresponding to a process reversible but not **predictable**" (It is not clear in which sense such a **process** could be reversible).

"4. Creation of distinctions together with destruction of distinctions: This can be modeled by a many-to-many relation, corresponding to a **process**, irreversible and **unpredictable**" (p.427-8)

0960

DISTRIBUTED MEANING (Principle of) ²⁾³⁾

The complete characteristics or **meaning** of an **element** in a **set** of interconnected **elements** cannot be completely guessed from that single **element**.

This principle is a direct consequence of the system's nature, being the **interrelations** and **constraints** as important as the proper qualities of any **element**.

The principle is very general. For example, in any word, composed of sounds and syllables, "the acoustic **cues** for each sound (are) distributed across the entire word" (Ph. LIEBERMAN, 1997).

In the same way, the shades of meaning of a word in a sentence can be wholly perceived only within the sentence, and even in some cases within the whole **context**.

The same is true of cultural **elements**, whose more significant meaning can be captured only within a social **behavior**, as for example a **ritual**.

→ **Memory (Distributed)**

0961

DISTRIBUTER ^{1) - 2)}

"The **subsystem** which carries **inputs** from outside the system or **inputs** from its **subsystems** around the system to each **component**" (J. MILLER, 1978, p.3).

The distributor is one of the **20 critical subsystems** in J. MILLER **taxonomy of living systems**.

0962

DISTRIBUTION ²⁾

"The relation which is **commutative** and **intransitive**" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.33).

Grains of sand in a dune do accumulate in a **commutative** way, as the **order** in which they accumulate is irrelevant. Moreover, since they are directly in contact (i.e. without any sequential ordering), their distribution is not **transitive**. This implies that there is no **structure** of any kind.

However, distribution as defined by FEIBLEMAN and FRIEND is a primitive and rudimentary form of **coordination** between **elements**: An **environmental** force, the wind, modifies at any moment the distribution of the grains of sand on the dune. No distribution of this kind becomes more significant than any other, at least if the **environmental** force shows a strictly **random behavior**, which is seldom the case in concrete situations.

0963

DISTRIBUTION (Clustered) ^{1) - 2)}

H.T. ODUM writes (referring himself to **ecosystems**): "Individual plant species are not evenly spread but are concentrated in zones according to their specialized **adaptations** to local conditions. More than one species is interspersed in the same kind of **environment**, because **networks** need diverse pathways... **Random** distributions are rare" (1971, p.72).

ODUM observes, moreover, that **consumers**, such as "ants, antelopes and people" tend to become clustered, "... because their complex **functions** are favored by grouping" (Ibid).

All this is related to the ways **flows** of **energy** circulate within the **environment** and to their progressive concentration into systems of a higher **level** of **complexity**, which prove more apt to capture them.

The concept is related to LOTKA's '**world engine**' and to **hexagonal distribution** in human settlements.

0964

DISTRIBUTION (Fractal) Law ²⁾

The number of **elements** is in inverse proportion to their **size**.

This is not absolute, but it applies nevertheless to many sets of **elements**. An example is the number of asteroids in relation to their **size**.

0965

DISTRIBUTION (Hexagonal) ^{2) - 4)}

A distribution characterized by the shaping of hexagonal **structural** and **functional nets**.

The hexagonal distribution model has been proposed from widely aparted quarters.

It appeared in hydrodynamics in BÉNARD's **dissipative** cells **structures**, which are produced in a boiling liquid through convective currents resulting from differences of temperatures when the liquid is heated up to boiling point in a vessel.

Dissipative structures (not necessarily hexagonal) became later on a very important tool in **Thermodynamics** of **systems far from equilibrium**.

This type of description was also introduced by W. CHRISTALLER (1933, 1937), describing the **embedded** and concentric hexagonal **nets** which appear in many human settlements. This theory was considerably extended by A. LÖSCH. (1944). See "**Hexagonal space filling**".

The reasons explaining hexagonal distribution are now clearer: in an **isotropic space** various competing **dissipation processes** in reciprocal contact adopt an hexagonal repartition seemingly because it is the most efficient manner to occupy space. However, as no **space** is absolutely **isotropic**, the **model** is only an approximation.

0966

DISTRIBUTION (Hierarchical) ^{1) - 4)}

The result of the progressive **propagation** of a **phenomenon** or **process** around one or various original centres.

The original centres of diffusion actuate as kinds of permanently active **sources** producing **elements** that will progressively migrate at growing distances and eventually generate secondary centres.

Such secondary focuses are generally produced by a discontinuous jump at a distance of some isolated **elements**.

The **process** will eventually lead to the **saturation** of wider and wider areas.

This very general **model** can be used for quantitative modelization of many different **processes**, as for example:

- propagation of epidemics or pandemics (P. GOULD and R. WALLACE, 1994)
 - expansion of **urban systems** (P. ALLEN, 1982)
 - progression of invasive vegetal and animal species
 - diffusion of technical innovations.
- **Percolation, System (Composite)**

0967

DISTURBANCE¹⁾

1. "That which displaces, ... moves a system from one **state** to another (W.R. ASHBY, p.77, 1956).
2. "Any relatively discrete **event** in **time** that disrupts **ecosystem**, **community** or **population structure**, and changes **resources** availability of **substratum**, or the physical **environment**" (St. PICKETT & P. WHITE, 1985 – as quoted by S. REICE, 1994, p.427).

While ASHBY's definition is more general, the second one is more useful in relation to **concrete systems**.

REICE states: "This **description** defines disturbance as a physical **event**, not as the biotic outcome of the **event**. I view a disturbance as a physical force such as a fire, flood or tornado that damages natural systems... The first impact of a disturbance is always to remove **organisms**" (Ibid).

This concept can easily be extended to an ample **variety of human systems**.

REICE adds various interesting comments: "Disturbance is **scale** dependent. If the area studied is large enough or the **period of observation** long enough, all disturbances are **predictable** and "normal" (Ibid). This means, of course, **relatively predictable**"

Still: "At smaller **scales** or shorter durations, disturbances appear completely **random**" (Ibid).

Moreover: "The **absence** of **predictable** disturbances (for example, spring snowmelt floods, or the arrival of snow in winter) often has a greater impact than their presence" (Ibid).

REICE refers himself to "disturbance **regimes**", which may command frequent, intermediate or only **long term** disturbances. Under the former one, "...the dominant competitors are reduced or eliminated, and colonizing species (assumed to be inferior competitors) dominate the system" and, "...under a disturbance **regime** that is intermediate in **frequency**, **magnitude** and intensity, some resident species persist in the system, along with colonizing species, which exploit the disturbed areas. Thus intermediate disturbance leads to maximum species richness" (Ibid., p.428).

Finally, long delayed disturbances tend to lead the system to a kind of **ageing**, with decrease of **variety (diversity)**.

However, "Disturbance *per se* does not determine **diversity**. It (only) creates opportunities for colonization of vacated **spaces** by new species" (p.431) ... of course if these are available from other **zones**.

Moreover: "Spatial **heterogeneity** and disturbance are interdependent. Disturbance creates patches, but **parchiness** modifies and sets the extent of the disturbance, – that is disturbance responds to the underlying **heterogeneity** of the **environment**" (p.434).

Generally speaking systems show **adaptability** to disturbances.

A last important aspect is that : "In some systems the return **frequency** of disturbance is so long that the impression of **equilibrium** conditions develops. This is what underlies the traditional idea of **climax communities**".

These very significant **models** should be pondered by anybody who wants to interfere with natural **ecosystems**. Their **validity** should as well be considered for **modelling** disturbances of **human systems** and their reactions to these.

It is important to note that disturbances can be **endogenous** or **exogenous**, even if an environmental disturbance is generally the remote or direct cause of the endogenous one.

0968

DIVERGENCE²⁾

The progressive differentiation and separation of **processes** in a system.

Divergence leads to the decrease of **interactions** among some **parts** of the system and is characterized by the slackening and possible final rupture of internal **communication**.

Divergence may lead to the break-up and **dispersion** of the system into unconnected **parts**.

Divergence and convergence

In a different **meaning**, as the opposite of **convergence**, divergence is the progressive **drift** of a **process** away from its planned **development** and may lead to great losses of **resources** and **time**. In any planned **process**, permanent or iterative **monitoring** of divergences should be provided for.

0969

DIVERSIFICATION¹⁾

The progressive increase of **variety** in systems.

Diversification seems to be a general property of evolving systems. Stellar systems, vegetal and animal species, individual **living systems**, **ecosystems** and **sociosystems** become more differentiated in **time**.

This seems a result of their **development** in at least three interconnected aspects:

- original constitution which offers them a specific potential for acquiring **variety**.

- original constitution which offers them a specific capacity for absorbing increasing **inputs** of **energy**.
- environmental conditions which allows for some **adaptations** or **transformations**, but inhibits others.

This last condition is the one which establish final **limits** to diversification.

0970

DIVERSITY^{1) - 2)}

The presence of different types of **elements** in a system, or of systems in an **environment**.

This is a quasi-synonym for **heterogeneity**, or in a slightly different sense, for **variety**. Diversity is a condition for "check-and-balance" and helps to maintain **dynamic stability**. As noted by J.T. BONNER it can be viewed as a measure of **complexity** (1988, p.101). Man is presently suppressing much natural diversity and is thus engaged unconsciously in a possibly dangerous experience. It is however for the moment impossible to judge the possible results of the artificial diversity he is introducing through, for example, genetic engineering, **artificial intelligence**, etc., all of which can be considered as **disturbances**, in a very general sense.

A wider definition refers to the presence of numerous different types of **elements** in some extension of **space**.

Diversity results basically from the slowing down and more complete use of the potential of **energy flows**. This is obvious in the mean-dorous circulation of energy in ecosystems (A. LOTKA's **world engine**). It may however even be the case in cosmic, stellar and planetary diversification. LAVILLE's **subdividing vortexes** and STULMAN's **fields within fields** are related subjects.

A cybernetic theory of diversity has been constructed by W. Ross ASHBY, under the name of **variety**.

An important degree of diversity is a basic condition for **dynamic stability** in **ecosystems**. Thus the present massive elimination of many kinds of natural animal and vegetal species by man is probably conducive to a greater general **instability** of all **ecosystems**.

C. WILLS writes: "Safety lies in diversity, and **evolution** should increase this diversity" (1996, p.41)

Range of diversity

J. WARFIELD uses the concept of diversity in his "**Interpretive Structural Modeling**" and in his "**Generic Design**" methodology to measure the **range** of diversity of beliefs and ideas in any **group** participating in ISM or GD.

He uses a **scale** from 1 to 10 to measure the degree of agreement or disagreement among participants on **evaluations** and ideas. A diversity range of more than 5,0 is quite frequent

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

and shows that disagreement is more common than **consensus**. This **knowledge** is important to avoid **underconceptualization** by a superficial assessment of **situations** and opinions.

0971

DIVERSITY GENERATOR ²⁾

Any device which introduces new **variations** within a system.

A diversity generator produces generally **random** variations. Such a device is about the opposite of ASHBY's **variety reductor**.

It is basic for **evolution**, because some variations can be useful and be retained by **selection**.

0972

DIVERSITY INDEX ²⁾

A measure of diversity created by SHANNON and WEAVER.

Diversity indexes take in account the number of different **classes** or types and the number of **elements** per type. Diversity indexes are widely used in **ecology** (S. REICE, 1994, p.428).

0973

DIVISION OF LABOR ⁴⁾

In any socialized **group**, the subdivision into distinct subgroups for the carrying out of some specialized **tasks**.

The original idea was developed by Adam SMITH in his "Wealth of Nations" in relation to **Economics** (1776).

However it is now clear that division of labor is a very general societal property. It can be found in insects societies and even in slime molds (*Dictyostelium discoideum*) and in some bacterial **colonies** (Anabaena) (J. SHAPIRO, 1988)

0974

DOMAIN ^{1) - 2) - 3)}

"A closed **universe** of existence which we can never cross the **boundary** of, once we are in" (G. KAMPIS, 1989, p.89).

A domain delimits the **set** of possible **transformations** for a system. Domains are the results of the establishment of **coordinated constraints**. M. BODEN gives as an example the classical **rules** of harmony in music.

No important work can be done outside the **constraints** of some domain. New domains can be created only by breaking existing **constraints**, and *replacing them with others*, possibly less stringent, or more productive, or simply different.

This implies at least in some measure, that we are mental prisoners within ourselves (and should thus try to take the measure of our inner mental **space**).

The KAMPIS definition is inspired from G. SPENCER-BROWN and F. VARELA, i.e. is related to the concept of **organizational closure**, by virtue of which the system is maintaining its own **organizational invariance**.

KAMPIS comments: "The most important point is that a domain has its **own structure** that cannot be studied directly from another domain (for instance, by an **observer**), it can only be approximated by the internal **structure** of another domain. Of course, different domains might have parallel **evolution** and this enables the formulation of approximate scientific laws that represent, to some extent, what is going on in another domain. However, our original interest is in the things themselves and it is a disappointment (faced by scientists of this century) that they are not available directly" (p.89-90).

This aspect is important for **systemic epistemology**.

0975

DOMAIN in Generic Design Science ¹⁾

J. WARFIELD describes as follows the domain comprised in Generic Design: "A major product of subsumptive scientific studies, which subsumes **components** from various disciplines, as well as **knowledge** not connected to disciplines, and **knowledge** relative to applications" (1991, pers. comm.)

Without any specific one of these **components**, design remains insufficiently founded and its results uncertain.

→ **Quality Control**

0976

DOMAIN of ATTRACTION ^{1) - 2)}

"A **region** in a **state space description** of a system within which the system **behavior** is localized indefinitely unless there is a **change** in system **structure** or a large **exogenous disturbance**" (T.F.H. ALLEN & T.B. STARR, 1982, p.266).

This definition corresponds to a regional and temporary specific **stability cycle** within a more global one.

Domains of attraction have **boundaries (separators)** corresponding to their influence **limits**. They correspond to the **topological concept of basin**.

A **variable** or a system may escape of its domain of attraction as a result of some exceptional **perturbation** which puts an end to its specific **dynamic stability**. This happens through a sudden **discontinuity** or leap (**catastrophe**).

It does not however necessarily imply the destruction of the system, which may have alternative possibilities of **dynamic stability**, within other domains of attraction. If such is the case, the system is said to have **resilience**.

Many ecological, economic and social systems have variable possible domains of attraction and trade some lesser **dynamic stability** for a better capacity of survival through **resilience**, as stated by C. HOLLING (1976, p.81).

0977

DOMAIN of RESIDENCE ²⁾

The **dynamic stability** area in **space** and **time** wherein the **processes** of a system remain constrained.

This concept has been introduced by C.S. HOLLING (1986) in order to specify the **limits** of **resilience** of a system. It closely corresponds to the concept of **domain of attraction** (possibly **Markovian** or even **chaotic**).

At its **boundaries**, the domain of residence also expresses the resistance of a system to contraction under **perturbations** produced by its **environment**.

0978

DOMINANCE ^{1) - 2)}

In an **ecosystem**, the **control** by one species of the basic conditions of existence of other species, members of the system.

In systemic terms, dominance implies the establishment of a **hierarchy** and is characteristic of any **socialization process**.

According to R. FULLER and P. PUTNAM dominance is acquired through a **random search process** "... usually stopped by a sequence or combination of acts" (1967, p.104).

The dominant species controls the **energy flows** and the power **circuits**. For example, birches, oaks or palm trees control the micro-climatic conditions wherever they become the main **element** in the wood, which implies that some species can survive, and others cannot.

Within an animal **group**, dominance tends to instaurate a **hierarchic order** that will diminish the wasteful use of **resources** due to infighting, and increase the global **efficiency** of the **group**.

0979

DOMINANCE (Relative) ²⁾

According to R.W. FULLER and P. PUTNAM: "A relative dominance that takes hold relative to one **random search**, has a logical **feedback**, reshaping all the others. It may be incompatible with some others and upset by the **effect** of some others, so as to produce an alternation... The establishment of relative dominances introduces elements of **order** into the **sets** of mutually exclusive **behavioral elements**" (1967, p.105).

Processes of this kind seem connected with the shaping of **behavioral algorithms**, which thus should reflect the progressive reduction of **randomness** within the **network**.

0980

DOMINANT PROGRAMMING→ **Programming (Dominant).**

0981

DORMANCY¹⁾

The condition of a potential **process** in a system that has not yet been activated by a specific **trigger** factor.

A state of very reduced **activity** of a system, that remains able to be reactivated under certain conditions.

Such a factor is generally a **disturbance** whose origin is in the **environment** of the system. The **activation** of the dormant **process** can however be indirect, or even possibly **endogenous**.

Escaping from dormancy, reactivation can be produced either by some **environmental** impact, or by some internal **agent**. In most cases it seems that the **action** of the internal **agent** is triggered by the environmental impact, as for example in plants and seeds after the dry season or winter.

In **living systems**, dormancy is mainly characterized by a considerable **slow-down** of **metabolism**.

0982

DOUBLE-BIND³⁾ - 4)

A mental, psychological or behavioral tangle produced by an incongruity – apparent or real – between two different **levels** of **contextual** explanation.

The famous self-contradictory **paradox** of EPIMENIDES the Cretan, saying that all Cretans are liars, is a typical example of a double-bind, leading to a logical contradiction.

As noted by R. VALLÉE, double binds are contradictory **constraints**, “generating unstable **behaviors**” and “belonging to **cybernetics of the second order**” (1993, p.95).

Double-binds leave us in a state of mental or psychological confusion and blocks our possibilities of efficient **behavior**.

This important concept, introduced by G. BATESON in 1956 (1973, p.173), has been thus commented by him: “We have learned from the **paradigm** of the freely falling body – and from many similar **paradigms** in many other sciences – to approach scientific problems in a peculiar way: The problems are to be simplified by ignoring – or postponing – consideration of the possibility that the larger **context** may influence the smaller. Our hypothesis runs counter to this **rule**, and is focused precisely upon the determining **relations** between larger and smaller **contexts**” (p.216).

This is a very important systemic and cybernetic notion, because it focuses our attention on the necessity to become conscious not only of the “horizontal” **interconnections** between **elements** or **events**, but also of the “vertical”

ones. Let us altogether take care that “horizontal” or “vertical” are no more than verbal **metaphors** about the supposed **organization** of our mental **processes**.

The subject is closely related to RUSSELL and WHITEHEAD's **theory of types**, from the logical viewpoint and to von FOERSTER's inquiry on **observing systems** (1981).

→ **E. BERNARD-WEIL Agonistics (1988).**

0983

DRIFT¹⁾ - 2)

A succession of **changes** in a system, obeying to no clearly definable **rules**.

Drift generally appears as a **random phenomenon**. This is because it results of various factors, none of them **dominant**, nor necessarily permanent or constant in its **effects**. Continuation of the drift is possible only if and when the occurring **changes** do not modify significantly the **interrelations** of the system or its **elements** with its **environment**, nor its basic internal **organization**.

Drift can be observed in many **phenomena** of very distinct types: in **population** genetics; in business **trends**; in political systems and even in **values** and **norms**.

To the opposite however, M. MARUYAMA states that: “At any one time a **random** initial kick (may) produce a **deviation** into a certain direction. **Deviation-amplification** takes over and this **deviation** is amplified consistently in the same direction. However, this cannot last very long, and soon **deviation** counteracting takes over, and the **population** becomes stabilized with certain characteristics. This **process** then repeats with other **unpredictable** drifts” (1976, p.86-7)

0984

DRIFT (Generic)

→ **Generic drift**

0985

DRIVE FACTOR¹⁾ - 2)

A permanent or recurrent excitation **input** which maintains **activity** in a system.

Such a drive factor reflects either some inherent internal **instability** of the system, or some external energetic **stimulus**. When sufficiently permanent, the drive factor leads to a **nonequilibrium situation** and eventually to **dissipative structuration**.

0986

DRIVER (Fundamental system)¹⁾ - 2)

“A system **variable** at the heart of the driving **mechanism** of the system” (K.E.F. WATT, 1992).

The FSDs are “**variables** (that) override all other systems **variables** in their **dynamic behavior** on the system” (Ibid). They could also be called “basic survival **variables**”.

WATT uses FSDs as a **forecasting** tool, to be applied to what he considers as the **long-term trends** (i.e. covering decades and centuries – as opposed to **extrapolations** from **short-term trends**), most basic for the future of mankind as a **whole**.

WATT considers present or probably imminent global **perturbations**: mass epidemics (AIDS), evolution of **energy** prices, climate **change**, total traffic jam and global pollution. All are obviously probable results of unsustainable exponential **long-term trends**

→ (See also “**Evolutive acceleration**”).

0987

DUALISM³⁾

The theoretical view according to which irreducible **distinctions** can be made between two entities.

The tendency to dualistic thinking is obviously a very basic characteristic of human nature (or possibly of the **brain's** workings).

Systemics is undoubtedly colored by dualism from its very origin, when distinguishing the “system” from its “**environment**”; or “**observer**” and “**observed**”. This bias is however at least partly corrected by the admission of multiple **interrelations** at many **levels** of **complexity**, as for example in **process theory**, in **dissipative structuration** or in **networks**.

→ **Dichotomy**

0988

DUALITY²⁾ - 3)

The twofold **distinction** between opposite aspects in **processes**.

L. CARLSON-SABELLI and H. SABELLI write: “Many systems theories highlight the existence of dualities, often understood as **complementarity**. BOHR's wave-particle **complementarity** is often stressed as a paradigmatic example... **Process theory** recognizes the existence of harmony and **conflict** (the *union of opposites*)... The **union of opposites** implies that it is incorrect to apply two-valued mathematical logic to reality” (1992, p.680).

This means that complementary opposites are not mutually exclusive in a radical way, but generate together a higher **level** of **complexity**.

Avoiding rigid **dichotomy**, J.van GICGH defines duality as “two extremes of a spectrum” (1978, p.590).

0989

DYAD²⁾ - 3)

A **set** of two **elements** or systems which interact in a specific and more or less permanent way.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Dyads are the most basic **structures** of any **complex system**. According to L. CARLSON-SABELLI and H. SABELLI, "The **interaction** of **opposites** creates the third dimension" (1992, p.681). This leads to the **triadic relation**.

0990

DYNAMIC GLOBAL MODEL ²⁾

A complex model including numerous different variable factors and the **interrelations** among them, whose understanding is affected by variable degrees of **uncertainty**.

L. PITEKA et al., referring to Dynamic Global Vegetation Models write: "Because they are global in scope, these models are necessarily coarse in some respects" (1997, p.472).

This explains why the predictive value of these models is always more or less uncertain. Eventual **disaggregation** of such models into submodels does not eliminate uncertainties because it can be done only by suppressing some specific **interrelations**, i.e. a crucial part of the modelled global system.

The authors give very interesting examples of this type of situations.

There is a clear similarity with related problems in FORRESTER's **Systems Dynamics**.

0991

DYNAMIC USE OF MODELS

→ **Models (Dynamic use of)**

0992

DYNAMICS ¹⁾

Classical dynamics was basically **deterministic**, in accordance – with **linear causality**, connecting **variance** of only one cause with the corresponding **variance** of one specific **effect**.

However, as stated by Y. SINAI, it became necessary to understand the conditions and ways by which "... a deterministic dynamics leads to the appearance of statistical laws... Secondly, why are statistical laws *stable*, i.e., why are they not destroyed by small **noises**, **fluctuations**, etc.? It has been believed for a long time that the appearance of statistical laws in **dynamic systems** was unavoidably connected with the increase of the number of **degrees of freedom** allowing for corresponding averages. It is now clear that... in important **classes of dynamic systems** with few **degrees of freedom**, or even only two, a strictly deterministic dynamics leads to the appearance of statistical laws" (1992, p.70).

This understanding led to the study of **ergodicity** and, later on, to research into the onset of **chaos** and **chaotic determinism**. See: "**Chaos (Onset of)**".

From another viewpoint, dynamics does not necessarily implies **continuity**, *at least in models*. Until now, we have no way to decide about dominance of **continuity** or **discontinuity** in the real world.

A.G. BARTO writes: "The term "dynamic" was originally associated only with **continuous-time models** since the differential equation was the only formalism available for **modelling processes** which unfold in **time**. We now know that the idea of dynamics is more general than the differential equation" (1978, p.167).

It is indeed now possible to *spread out automata's* dynamics through **discrete models**, as seen for example in CONWAY's "**games of life**", which are easily modelled on **digital computers**.

0993

DYNAMICS (Chaotic) ¹⁾²⁾

The **dynamics** of any system characterized by its **sensibility** to a set of interacting **initial conditions**.

In fact, chaotic dynamics corresponds to **nonlinear** features in the system.

The **behavior** of such a system cannot be rigorously predicted, even if it remains globally **deterministic**.

This seems to be due to the **anisotropic** and out of **synchrony propagation** of the multiple **interactions** within the system.

→ **Nonlinearity**

0994

DYNAMICS (Non linear) ¹⁾²⁾

Nonlinear dynamics as a field of **models** for **nonlinear processes** and systems include:

- **Bifurcation theory**
- **Chaotic dynamics**
- **Fractals**
- **Neural networks**
- **Power laws**
- **Quantum entanglement**
- **Renormalization**
- **Solitons**
- **Synchronization of chaotic systems**
- **Synergetics**

Nonlinear dynamics is a decisive development in all disciplines when strictly **deterministic** models are insufficient.

It has typically a **transdisciplinarian** character with applications in a broad range of fields from physical to biological and social sciences.

→ **Linear behavior; Linearity; Linearization; Mathematics of nonlinear systems; Nonlinear; Nonlinearity; Randomness; Randomness (Constrained)**

0995

DYNAMO ⁵⁾

"A special **simulation language** applied to **Systems Dynamics**" (J.van GIGCH, 1978, p.330).

This **language**, created by R. SOLOW, has been widely used for **simulations** inspired by J. W. FORRESTER *Industrial and World Dynamics*.

→ **Club of Rome, World models**

E

0996

ECHELON ²⁾

The **organizational level** in M. MESAROVIC et al. taxonomy of hierarchical levels (1970, p.37).

0997

"ECHO" ^{2) - 5)}

"A **simulation** of an **ecosystem** in which **digital organisms** try to survive and reproduce".

This **model** has been created by J.H. HOLLAND.

R. RUTHEN describes it as follows: "All **organisms** are endowed with "chromosomes" that encode offensive and defensive **strategies**. Each **organism** wanders through an artificial **environment**, searching for **resources** and absorbing them into an internal reservoir. If one **organism** encounters another, the two fight, and the winner consumes the loser, acquiring all the **resources** contained in the loser. If an **organism** obtains enough **resources**, it produces offsprings whose chromosomes may contain mutations. New species arise with even more elaborate **strategies** for offense and defense" (1993, p.113).

Initially these **simulations** did not consider **cooperation**. HOLLAND, inspired from R. AXEL-ROD *Prisoners's Dilemma* introduced three modifications:

"First, each **organism** can choose to fight for **resources** or trade for them. Second, each is assigned a tag, which is analogous to a molecular **marker** on the **membrane** of a **cell**. Last, each **organism** is allowed to develop **rules** such as "fight only those **organisms** that carry a red tag". If **strategies** and tags are initially assigned at **random**, some **organisms**, by luck, are more inclined than others to use a **strategy** resembling tit for tat. Those that play such **strategies** are more likely to survive and reproduce, thereby perpetuating the existence of particular tags."

According to HOLLAND: "What started out as a completely **random** juxtaposition of tags and **strategies** begins to develop in a very organized way" and "In the end the **digital ecosystem** displays both speciation and **cooperation** – and such **deviations** as mimicry and lying" (Ibid).

This is again a kind of collective **automaton** in the making and could probably be used to modelize complex economic and social **behavior**.

0998

ECO→ **Contingency (mutual)**

0999

ECO-CUBE/KNOW MAP¹⁾²⁾³⁾

The Eco-cube is a three dimensional **knowledge representation** proposed by H. BENKING.

It was practically realized for the first time in June 1990 at the Exhibition "Global change-Welt im Wandel" that took place at the Bundeskanzler Amt in Bonn, Germany.

It is a kind of upgraded "Rubik's cube of Ecology".

Alike the Rubik cube, the Eco-cube is made of smaller also cubic **elements**

The third dimension is needed "in order to be able to dive into **information**, instead of surfing on the surface, subject to many influences which can distract us".

Benking adds: "We will have to share exploration in order to share common ground. We have to bridge and switch between **models** and **scales**, as one **representation** is not enough, and seeing from various distances, with different focus, lens and filters will help to establish common **references** even in uncharted terrains and vertical realms"

The basic point is "to put different **observations** into a single **context**".

Benking also refers himself to DOXIADIS's **ekistics**. For a complete written and graphic information see: <http://benking.de/Global-Change/spatial-spacial.html>

Benking writes: "We can build **models** like 1x1x1 meter or 20x20x20 meters, where objects in **fields** of (survey) **knowledge**, subject areas or discipline **domains** form one dimension, and in another dimension we have **scales** to see if this field is located in the micro-, meso-, or macrocosm, covering a small or large scale".

→ **Macroscopic; Multiperspectivism; Panorama thinking; cognitive spaces**

1000

ECO-INVASION¹⁾²⁾⁴⁾

The colonization of a new **territory** by a vegetal or animal species.

Hundred of dramatic cases are known on all continents. New ones appear every year. Some of them generate enormous economic **costs**, as for example the South American water hyacinth in Central Africa and in South Asia.

Eco-invasion is perhaps the most significant ecological issue of our time. It started to be an important **phenomenon** at the time of the great geographical discoveries and its main **agent** has been, and still is, man. (See Chr. BRIGHT, 1998)

An invading species is frequently devoid of any natural **parasite** in its new settings. Moreover it benefits in most cases of some advantage as a competitor or predator of older established species. As a result, more than a third of all endangered species of the world are victims of exotic invaders.

From a systemic viewpoint, it is a result of massive development and acceleration of world **communications**, which are connecting in an evermore efficient way **biotopes** which were formerly isolated from each others.

The model could be of interest in **social sciences**.

1001

ECOLOGICAL RELEASE⁵⁾

A sharp decrease in competitiveness in an **environment** where numerous individuals or species have been suddenly eliminated through some catastrophic **event**.

In such cases, the rare survivors have an exceptional chance to massively increase their stature and/or their numbers. This **phenomenon** can be observed in a forest clearance or on recently cooled lava flows.

It has been conjectured that the massive evolutive radiation of big dinosaurs was caused by such an event. It was also possibly the case of the sudden success of mammals after the seemingly catastrophic demise of the dinosaurs.

It would be interesting to see if an analogous **effect** takes place after catastrophic social upheavals (as for example **pandemics**, destructive wars or great economic crashes).

1002

ECOLOGICAL SUCCESSION⁵⁾

The **process** of progressive reestablishment of an **ecosystem** after a strong **perturbation**. (E.P. ODUM, 1997).

The reorganized **ecosystem** may be, for some time or definitively, different from the original one, depending on steady or changing **environmental** conditions.

The succession is predictable within limits. It can be deeply affected by **human action**. For ex. cultivated land can replace forest in a definitive way and complete reversal may never anymore be possible.

1003

ECOLOGICAL TRAP^{1) - 2) - 4)}

Any **situation** in which a **population** perturbs its **environment** to the point of being unable to survive.

G. VICKERS, who introduced the expression, explains it as follows: "A **population** in a favourable but unfilled **habitat** normally multiplies at a constant **rate** until it meets or breeds limitations which slow and in **time** arrest its **growth**. It may then stabilize, at or below its

maximum, in the same or an altered form, with **oscillations** of less or greater **amplitude**; or it may even disappear, because in its period of expansion it has either **unfitted** itself for life in a limited **environment** or **unfitted** its **environment** to support even a limited **population**" (1967, p.61).

This is a much more subtle and adequate formulation of the old Malthusian principle. There is probably nothing more important for mankind in all system science than this nugget of ecological wisdom.

→ **Overcrowding; Undercrowding**

1004

ECOLOGY¹⁾

The science of **interactions** of **living systems** among themselves and with their **environment**.

Already in 1866, E. HAECKEL defined ecology as the global science of the **organisms** relations with their surrounding world, in which he included generally all the conditions of their existence.

Later on, scientists like A. LOTKA (1924, 1956) and V. VOLTERRA (1931) studied more restricted **phenomena** as, for example the **interrelations** of two or three species. Others considered mainly lesser biotopes: a meadow, a small island, a wood.

However, more recently, HAECKEL's programme has been retrieved as it becomes ever more obvious that these restricted inquiries should be put into the perspective of a much more global **understanding**.

The French ecologist F. RAMADE writes: "Ecology studies **complex systems**; its approach is thus, ipso facto, of a **holistic** nature. Its object is at the summit of the organizational ladder of **living systems**: The simplest biological entity of its concern is the **population**. Furthermore and by order of growing **complexity**, its objects of study are **colonies**, living **communities**, **ecosystems** and **biosphere** as a **whole**" (1993, p.424).

Ecology is thus a typically systemic science.

1005

ECOLOGY (Computational)⁵⁾

The computer **modeling** of **emergent** and **autopoietic** properties in **networks** of interacting **artefacts**.

S. GOONATILAKE states: "As **Artificial Intelligence** devices and **communication** devices become increasingly interconnected, **patterns** of **information** classification and of **information processing** are allowed to form spontaneously from unplanned **interactions** that arise from within the system itself. In doing so, these devices enter into the realm of **autopoietic**

processes". Furthermore "Some of the evolutionary characteristics revealed in these systems are reminiscent of **punctuated equilibrium** in biology" (1991, p.163-4).

The **emergence** of **autopoietic** properties was first modeled by F. VARELA, H. MATURANA and R. URIBE (1974) and developed by M. ZELNY and N.A. PIERRE (1976).

The subject is closely related to **connectionism** and **connection machines**.

1006

ECOLOGY OF ACTION

→ Action (Ecology of)

1007

ECOLOGY of IDEAS³⁾

G. VICKERS stressed: "... the need to develop concepts of **stability** applicable to appreciative systems" considering that: "All **communication** – and hence **cooperation** – depends on (such) *shared*... systems, on ways of conceptualizing and valuing which are systematically organized and which, when they change, may have to change extensively before they reach anything approaching a new **equilibrium**" (1970, p.182).

Of course, ideas are carried by people and appreciative systems are a *collective* tool, obtained by *consensus* (always *provisional*) and selectively transmitted by people through time. (KORZYBSKI's *time-binding*).

1008

ECOLOGY of KNOWLEDGE^{1) - 3)}

"The study of **patterns** of **interrelationships** among the various "species" (**subsystems**, sub-subsystems, etc.) and **fields** and subfields of **knowledge** with emphasis on:

a) preserving the condition of dynamic balance between the "species" and their **environment**; and b) **optimizing** the overall **sybiotic** fruits of **synergistic interactions** among them" (J.W. CLARK, 1972, p.168)

CLARK proposed a curriculum in "General ecology of **knowledge**" divided as follows in five sections, including among other subjects:

A. Systems Education Studies

Systems approaches;... **simulation**;... systems **management**;... **game theory**;... **forecasting** methods and **operations research**.

B. Basic Integrated Studies

General **cybernetics**;... eco-cybernetics;... meta- tools;... meta-skills;... **metalan- guages**;... general ecology of **knowledge**

C. Global Design Heuristics

Heuristic forecasting;... **synergetics**;... synergetics;... **pattern recognition**...

D. Heuristic Meta-Policy Studies

The anatomy of meta-policy;... the anatomy of **change**;... Psychology of mass movements;... systems of **signals** and incentives;... **games** for global involvement;... the **dynamics** of **feedback** and **reinforcement**...

E. Meta-Policy Sciences

Behavioral sciences and general systems perspectives;... designing and evaluating alternative futures;... integrative workshops

For the discussed complete program, see reference (p.165-180).

This proposal, made in 1972, does not seem to have been seriously debated and, still less, applied anywhere. The institution of *interfaculties* **programs** of this type would possibly be the only way to seriously expand the **systemic approach** and **methods**.

1009

ECOLOGY of MIND³⁾

This expression has been coined by G. BATESON, who admitted that: "Perhaps '**epistemology**' is only another word for the study of the ecology of mind" (1973, p.372).

It could however something more specific, as there are no two identical "minds" (i.e. **brain network organization**), while **epistemology** pretends to establish general **rules** for **validation** of **knowledge**.

1010

ECOLOGY (Somatic)

→ Somatic Ecology

1011

ECO-MATRIX²⁾

An **input-output matrix** used to represent in a tabular form all the possible **interconnexions** within an **ecosystem**.

A non-existent **interconnexion** is represented in the matrix by 0 in the corresponding intersection.

The matrix is an alternate **representation** of the corresponding **network diagram** and its use has been proposed by H. ODUM. This author gives as an example a matrix of the **steady state flows** of carbon in a microcosm grouping CO₂, its organic **storage** and its living producers and users.

This form of **representation** allows for "... the use of techniques of matrix algebra by systems analysts" (1971, p.20-21).

1012

ECONOMICS in systemic terms^{1) - 4)}

Elaboration of economic theory and practice in systemic terms is still largely a pending subject, in spite of the relentless efforts of K. BOULDING, one of the three founders of the I.S.S.S. (1952, 1968, 1972 and 1978).

J. WARFIELD observes: "The failure of economics schools of thought to provide an adequate basis for governmental policy is directly related to the **complexity** of the subject and the absence, within economics, of any **strategy** for dealing with that **complexity**". He also denounces the unwarranted simplifications in economics **models** of human **behavior**: "... it is clear that the postulated human being found in economics theory has little in common with most human beings" (1990a, p.66-7).

Such criticism is aimed at capitalist as well as at marxist economics.

M. MARUYAMA, in turn, observes that economic theories – and their practical prescriptions – depend on the **mindscapes** of their respective authors.

An **Homogeneist-type** formulation "assumes that the **cause-effect relationship** goes from the **key variable** to other **variables**. **Causal loops** are either ignored or paid lip service" (1994, p.9). Such minds select "*the cause*", "such as the social security system, the credit card system and even the education system". For an **Heterogeneist randomizing mind** "If everybody... is self-sufficient, there is no economic problem (grow your own potatoes). Economic **interactions** among people are the cause of the problems. For the Heterogeneist cooperative mind, "the economic system is inherently **self-stabilizing** or **cyclic**. **Disturbances** are due to "**exogenous**" (non economic) influences, such as interferences by government and wars. "Laissez-faire is the best policy". And for the **Heterogeneistic cogenerative mind**, the economic system contains both **change-amplifying** and **change-counteracting loops**. Economic policy failures occur when **change-amplifying causal loops** are ignored" (p.9).

This last view is MARUYAMA's preferred attitude. While this "landscape of **mindscapes**" could be controverted, it emphasizes at least the generally ignored cultural and psychological roots of economic theories.

Historically, the impact of the economic activities of small, or even medium human **groups** on global **environment** was slight and could be ignored (even if some archaic and historic cultures were probably self-ruined by their own **environmental** abuse).

It is however not anymore possible to understand in a realistic way economic **processes** without settling them firmly on the base of **energy flows**, considered from a **thermodynamic** viewpoint.

This has been done by N. GEORGESCU-ROE-GEN (1971 and 1982); by H.T. ODUM (1971, 1976, 1991); by R.N. ADAMS (1975 and 1988), and more recently by J.R. PROOPS (1983, 1985, 1987) among others.

It is also impossible to support sound economics without taking in account another consequence of **thermodynamics**, i.e. the massive production of difficultly recyclable **waste** by producers and consumers and the resulting relentless **growth** of an enormous **ecological problem**. This subject has been widely studied, again by H.T. ODUM and, more recently by many others.

Other authors have considered the improper use and squandering of energetic and material **resources**, f. ex. D. PIMENTEL in agriculture (1977) and E. MISHAN, in relation to economic **growth** (1969 and 1987).

More recently, the subject of so-called "**sustainable development**" has been considered, while generally in a non-systemic way.

Unfortunately, the main currents in economic theory remain still unaware or indifferent to these insights.

Quoting H. DALY, CHANG-GEN BAHG defines the following basic systemic views about economics: "First, from the physical point of view, the economic **process** is an **entropic process**; Second, wealth is a kind of **open system** because it is produced in the **throughput process** which begins with depleting **matter-energy** of low **entropy** and terminates with extruding **matter-energy** of high **entropy**, in equal quantity in the **environment**; Third, the mechanical **phenomenon** is reversible (note from the compiler: this is arguable !), but the **entropic phenomenon** is **irreversible**...; Fourth, there is an **anti-symmetric** relation between two **sources** of low **entropy**, that is, on one hand, the total quantity of **energy** bearing low **entropy** of the sun is infinite (this again, is arguable, at least in principle!), but its **flow rate** toward the earth surface is finite. On the other hand, the total quantity of substance of low **entropy** on the earth, such as the ore condensed in crust, is finite, and these substances are doomed to exhaustion" (1990, p.93).

One more basic fact is that, as a planet, earth is a limited **sink** for useless non-**recyclable waste**, including most specially degraded **energy** (i.e. heat). This **problem** is now reflected in the possibility of a warming of the climates at global **scale**.

From another viewpoint, the reduction of human motivations to merely quantitative satisfaction of material needs suppresses the systemic aspects of the psycho-social and socio-cultural of human **behavior** and the **dynamics** – possibly emergent and/or chaotic – proper to the **evolution of human systems** as complex as empires, nation-states and even international business enterprises, whose **management** cannot be reduced merely to sales, profits, balance sheets, **input-output matrixes**, marketings, and the like.

In synthesis, the construction of a new economics in systemic terms (**ecological, thermodynamical, psychosocial, sociocultural, etc...**) is an urgent need.

A most important subject in this sense is **recycling**, which corresponds to the shaping of a more or less closed **cycle** economy, where only direct or indirect solar **energy inputs** would dynamize the **man-planet system**. In this way, the most sustainable economic **activity** would be secured with a lesser global production of **entropy**.

1013

ECOSPHERE^{1) - 2)}

The global physical, chemical and biological planetary interactive system.

The ecosphere is now increasingly dominated by the **activities** of the human species, whose influence is globally disturbing it, through the excessive use of non-renewable **resources** and general abuse of its use as global **sink** for evermore numerous non-recyclable products.

1014

ECOSYSTEM^{1) - 2)}

A **community** of interconnected and interacting systems, depending of specific **energy inputs** and evolving as a **whole**.

The original definition as introduced by the british plant ecologist A.G. TANSLEY, was: "A community of **organisms** and their physical **environment** interacting as an ecological unit"(as quoted by F. CAPRA, 1997, p. 33)

R. MARGALEF describes the ecosystem most generally "... as the material **path** followed by **energy** that generally enters in the form of photons and goes out into an **energy sink**" (1968, p.14). In the mean-time, **energy flow** may construct less or more complex ecosystems, with however a tendency to maximize **complexity**. The more organized **parts** tend to have a selective advantage on the less organized ones, due to their better possibility to use and increase their **information**. According to MARGALEF: "This is an extraordinarily valuable principle not only in ecology but also in the **general theory of systems**" (p.28). See "**St. Matthew Principle**".

H. ODUM, in turn, describes the ecosystem as: "... a **network** of food and mineral **flows** in which the major pathways are **populations** of animals, plants and microorganisms, each specialized to live in a different way, doing a different job for the **energy flows** of the system" (1971, p.60).

He adds: "... the purpose of having many species is ... the increased system **effectiveness** possible with specialization, division of labor, and more kinds of **controls** and **regulatory circuits**"(Ibid). A. LOTKA "**world engine**" **model** is a closely related formulation of the same global concept (1956, p.334).

ODUM's **effectiveness** is somehow related to ecosystems tendency toward global stabilized **complexity (climax)** at the highest **level** of **energy flows** use. Such a closely limited **dynamic equilibrium** means that they are stabilized by countervailing **feedbacks**. However stabilized ecosystems seem to lose **resilience**, unless they are submitted to periodical **environmental disturbances**. Their very **complexity** helps them and simultaneously hinders them in this **process**. S. REICE contends that: "...**equilibrium** is an unusual **state** for natural **ecosystems**", and that "... the normal **state** of **communities** and ecosystems is to be recovering from the last **disturbance**" (1994, p.427).

This is coherent with St. KAUFFMAN's hypothesis according to which "Ecosystems **co-evolve** to the edge of **chaos**" (1993, p.261).

Living systems are particularly significant in many ecosystems, because they modified and go on modifying the **interactions** between the lithosphere, the hydrosphere and the atmosphere.

The planet is our global ecosystem (see **Gaia hypothesis**) and it is basically fuelled by the sun's **energy**, which has been and still is the prime mover of its **evolution**.

Ecosystems are in some sense **hierarchized** (but not truly **hierarchical**, as there are no specific **regulators** or **controllers**, with the dubious exception of man himself, a disturber more than a **regulator**), i.e. simultaneously organized from more global to more local and specific ones "**top down**", but also conversely from the base **levels** to the upper ones. This explains that a vast ecosystem can be deeply transformed by the intrusion or elimination of some apparently unimportant **class** of **elements**.

Some specific smaller ecosystems can be more or less isolated within more global ones, at different **levels**, as for example: the "tropical rain forest", some specific tropical rain forest, some small specific **patch** of the same, or even, **part** of the canopy corresponding to this **patch** or the bark of one specific tree. Of course, the **environment** should never be totally forgotten.

G. BATESON, as well as many other authors, emphasizes that: "We are rapidly, of course, destroying all the natural systems in the world, the balanced natural systems. We simply make them unbalanced – but still natural" (1973, p.406).

We should never forget that any **change** of one **part** necessarily implies and triggers **changes** – frequently **unpredictable** – in the other **components**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The introduction of **chaotic models** seems to be an urgent need in ecosystemics.

1015

ECOSYSTEMIC RELATION ^{1) - 2)}

E. MORIN enunciated the following double principle about the **interrelation** between a system and an **ecosystem** which supports it: "The system responds by way of its own **determinism** to the **randomness** of the **ecosystem** while it responds in an **aleatory** way to the **determinism** of the ecosystem".

MORIN explains this apparent contradiction in the following terms:

"1. The system opposes its **determinism** to the **randomness** in the **ecosystem**."

"The **self-organizing system** creates his own **zone of determinism**: the difference between a similar agglomeration of **cells** when living or dead is that while the first one conforms an **organism**, a system obeying its own **determinism**, the other one obeys the physico-chemical **determinism** of the surroundings."

"The **living systems** fight by multiple **means** the destructiveness immanent in the surroundings... they tend to reduce the external variations... (and) to impose their law, against external adverse conditions."

"a) The system tends to dampen variations of the external **medium** and imposes within itself its own **constancies**: this is **homeostasis**... The **negative feedback** is the well known **regulator** which contrasts the **random perturbation** and re-establish the **homeostatic state** wherever it has been affected."

"The "system produces a non-**random response** to a **random event**, at the very place of the **circuit** where the **random event** took place" (as quoted from G. BATESON, 1967)."

"b) The system tends to impose its own **determinism** on the **environment** in spite of adverse conditions. This is **equifinality**, by which a finalized **state** of the system can be reached, starting from different **initial conditions** and by different ways."

"2. The system opposes a **random variability** to the **environmental determinism**."

This is already the reverse of the former proposition, in view that a system able to create a **zone** of proper finality (in its **vicinity**) escapes in this way from some **effects** of the external **determinism**" (1972, p.180).

Thus the system obviates many unfavorable **environmental perturbations**, while becoming capable to produce **effects** in its **environment**.

P. VENDRYES had already expressed similar ideas in his 1942 book "Vie et Probabilité".

1016

ECOSYSTEMS DYNAMICS ^{1) - 2)}

According to B.C. PATTEN, as quoted by A. CASELLES MONCHO and J.L. USO DOMENECH "...ecosystems dynamics in non perturbed **states** is approximatively **linear**, although its internal **processes** were **nonlinear**" (1993, p.438).

"Non perturbed" should be understood as "not much perturbed", i.e. perturbed in a limited **stable range**. This is the case of mature ecosystems (formerly described as **climax**).

Moreover: "Biotic **components** of an ecosystem have limited **resources**". This explains why **stable** ecosystems, when seriously perturbed, may **irreversibly collapse** (The case for example of overexploited tropical rain forests, or overfished oceanic areas).

And: "Non perturbed **dynamics** is produced in a bounded **range of operations**... and: **Operations** occur in a bounded **range of values**" (Ibid).

This aspect has been tackled in a different way by W.R. ASHBY, who describes "equilibrium densities" and "terminal **equilibrium**" and uses **MARKOV chains** and **Markovian matrices** to modelize such **equilibria** (1956, p.177).

Ecosystems can also undergo strong **perturbations**, which may put an end to their **homeostasis**. One case is the appearance of a mutant **population** that deeply affects the global **equilibrium** of the system. In such a case it will self-reorganize in a new way, probably at a higher **level of organization**.

Another case is the destruction of an important **component**. This may lead to a crash, i.e. to a globally lower **level of organization**. In many cases the **introduction** of an alien **component** may bring such a havoc: For example goats or rats and cats on formerly isolated ecosystems.

1017

ECOTONE ⁵⁾

The blurred **transition zone** between an **ecosystem** and its **environment**.

In this **zone**, **parts** or **elements** of the **ecosystem** can be affected by **edge effects**, as they must adapt to **disturbances** or different conditions originated through local (and sometimes **fractal**) inroads of their **environment**.

The **effect** is frequently observed in burned down **patches** in a forest, or at the **edge** of a mangrove, or close to the **boundary** of forest and cultivated land.

The ecotone model could possibly be extended to sociology, in relation to cultural or social exchange, or mutations near **boundaries**.

1018

ECTROPY ^{1) - 2)}

"...the ability of **open** and organized **systems** to use the **environmental** substances, rich in easily released **energy**, to maintain... a given **level of entropy** or even to lower it" (V.I. KREMYANSKIY, 1969, p.142).

Systems do this as they "maintain irregular **distributions (gradients)** of substance concentration and support synthesis **processes** founded on the binding and simultaneously the dispersing of **energy**" (Ibid).

The concept was imagined by AUERBACH, according to whom "...life is an **organization** created to avert the menacing **entropy-death** of the universe" (L.von BERTALANFFY, 1969, p.77).

BERTALANFFY states: "Ectropy does not exist. However, **thermodynamics** was concerned only with **closed systems**, and its extension to **open systems** leads to very unexpected results" (Ibid).

Originally the notion of ectropy was no more than a purely verbal explanation, in finalistic terms, of a still quite ill understood **situation**, i.e. the existence of some compensation to the **entropic** degradation of **energy**. More recently, PRIGOGINE and his school developed the new **thermodynamics of open systems** and extended it to the **irreversible systems** with structuring **dissipation of energy** and eventual **emergence** into higher **levels of complexity**.

However, in his 1960 paper, KREMYANSKIY was already giving a satisfactory **meaning** to the concept of ectropy.

1019

ECUMENOPOLIS ⁴⁾

The coming planetary global human system with its corresponding ecological **environment**.

The term has been introduced by C.A. DOXIA-DIS, the founder of **ekistics**

→ **Ecological model of the man-planet system**

1020

EDGE EFFECT ^{2/5)}

The modifications in the **parts** of the system close to its **boundary** resulting from influences of its nearby **environment**.

This concept relativizes somewhat the one of **boundary**, specially in **ecosystems** wherein no **boundary** can be neatly established. In **ecology**, the edge of an **ecosystem** is also called "**ecotone**".

The effect has been observed, for ex. in isolated forest **patches** in Amazonia after the clearing of their **environment**.

B. HOLMES writes: "For the first few years, the forest floor is warmer and drier for at least 60 meters in from the edge... This burst of light and higher temperature has a profound effect

on the tree seedlings that dot the forest floor. A lot of these small seedlings will die off, and others that are adapted to drier conditions will take over" (1996, p.36).

However, when the cleared **environment** returns to more bushy conditions, this edge effect decreases and finally disappears.

Edge effects seem probable in any system composed of a **variety of elements** whose **behavior** may respond in different ways to a **variety** of conditions and become submitted to the influence of a transformed **environment**.

Edge effects may lead to "ecology-driven speciation" (J. ENDLER, as quoted by K. BROWN, 1999, p.48)

They are probably present in human systems where these conditions sometimes happen.

→ **Herd effects**

1021

EDUCATION ^{1) - 4)}

The **process** of acquiring or transmitting the condition of becoming and being a biologically, psychologically, mentally and socially well integrated person.

What must be obtained through education is an adaptive set of **values, norms** and **habits** tending toward the avoidance of dangerously incoherent or conflictive **situations** at any **level** (in J.G. MILLER's sense of the systemic **levels of complexity**, from **organism** on) or, when unavoidable, be able to make the necessary **adjustments** in the best possible way.

Education is at the same time a personal and a societal responsibility. It supposes a progressive training at the different **levels** of the nervous system, and particularly, the different **brain levels**. As adaptive **change** is becoming ever more necessary for the individual and in **social systems**, the historic rigidity in **values, norms** and **habits** is becoming inadequate. Education should now include the **understanding** of **change** in natural and human **environments** and the conditions and ways of obtaining a better **fit** when needed.

It should thus tend to adaptive and permanent **autonomous self-regulation** through the frequent critical review of one's **frames of reference**.

1022

EDUCATION (Dimensions of systemic): The technical and organizational angle ⁴⁾

B. BANATHY proposes a three-dimensional structuring for systemic education, in order to take in account the whole complex setting of the educational **situation**. He writes: "The usefulness of a three-dimensional structuring (**content**, target groups, **context**) can be seen

when we consider the analysis **design, development**, implementation, and **evaluation** of systems education in terms of such enquiries as what kind of systems education is best suited for what kind of people and in what kind of **contexts**" (1993, p.287).

BANATHY's views make it readily evident that no really useful educational scheme can be reduced to **methods**, or material **means** only. Nor is it positive to consider education and **knowledge** transference separately. It is also obvious that systemic education should be co-participative, i.e. developed in common by the whole **community**, including the educandi themselves.

Concurrently, as observed by R. RODRIGUEZ DELGADO: "Design of educational systems should take into account not only systems specialized in education – schools, universities, research centers, etc. – but also the whole society. The family, the working place, the political institutions, the labor unions, the churches, the sports installations, the **communications networks** – telephone, radio, television, video, internet – are sources of constant **learning**, that frequently are noxious. A new educational system should try to influence the redesigning of these **learning sites**" (1990, pers.comm.).

Besides: "From the viewpoint of global societal **learning** it would be advisable to explore questions like the following:

"How to devise **methods** for quick **adaptation** of the school to **changes** in societal needs or desires.

"How to redesign schools and school systems in order to use **communications, informations**, video, compact discs, and other technologies for global societal **learning**.

"How to redesign the school to implement, among other things, the **functions** of an **information** center, serving not only the school, but also the **community**.

"How to redesign schools and school systems in order that they could contribute to integrated **community development**.

"How to make available to the learners free space – or computer software – in order to design new types of school in accordance with their wishes.

"How could design contribute to increase innovation and **creativity** among leaders" (ibid).

Let us however remember that all technological **means** are *neutral*, i.e. can be used for **any purpose**. The previous definition of the **purposes** is thus paramount.

Let us also remember that neither innovation, **creativity** nor wishes are necessarily bountiful, if a good **understanding** of natural, social and personal conditions and **situations** is not created, to begin with. (see hereafter).

1023

EDUCATION (Systemic) ^{1) - 4)}

A way to transmit, by an appropriate training, an integrated **understanding** of oneself and of one's **interrelations** with nature as a whole as well as with other people, eventually of different cultures, races, creeds and **languages**.

Nowadays, there is much talk about "education", but it is generally confused with "instruction", i.e. **knowledge transmission**, or training, which is now not much more than the acquisition of a specialized trade or **knowledge**. Instruction has slowly pushed education out of the classrooms and auditoria.

The school does not anymore bother much about religious belief, philosophy, **ethics** and civics. As to the practical art of living, i.e. how to live in peace with oneself, how to be a good husband or wife, a good father, mother or son, how to avoid the traps of modern life (racism, ideological fanaticism or stupidity, drug addictions, crime as an author or as a victim), how to respect nature's **equilibria**. All these do not now seem to be anybody's matter, at a time when the churches themselves become confused and the media seem to believe that ratings depend on blood, violence, cheap or degraded sex, terror and so-called sport (2, 10, or 22 players, *for money*, and 50.000 well named nerve-racked "fans").

Of course, our new problems, as for example our local and global relation with our **environment**, the impact on society of new technologies, the planetarization of many **situations**, are totally ignored by what we still dare to call "education".

And who has ever heard of training the common citizen to give him/her some **understanding** of politics, that most important social activity in order to allow him/her to distinguish clearly, and properly evaluate the rabble-rousers, the corrupts, the fanatics, the lightweights, the cynics, or simply the dangerously incompetents; and to teach her/him how to be a participative and responsible citizen, who does not believe in fairy tales.

In synthesis, older education does practically not exist anymore, and none adapted to the **complexity** of our present world did yet emerge, which is one of the main reasons why the fabric of societies is torn into shreds in so many places.

A **systemic-cybernetic approach** to environmental, societal and personal problems would help to recreate a suitable educative **frame**, basically by maintaining the natural **systemic-cybernetic** attitude of newborn, infants and children, who learn by **trial and error** (a **cybernetic process** based on **feedbacks**) and by slowly disintricating internal and external **complexity**: toddlers are the most accomplished systemists, which is why they survive.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Systemic **learning** and/or training should of course be adapted according to age and culture.

R. RODRIGUEZ DELGADO proposes the following general systemic approach to manage this situation:

"The **design** of educational systems for a complex world cannot be based in pre-established rigid formulas. However, some wide scope principles, like the following, could be generally accepted.

"a) Lack of dogmatism. Closed cultures tend to reject all other **ideologies**, showing themselves as the ultimate truth. Systems thinking, on the contrary, should be open. Criticism of the **systems approach** should be stimulated. **System theory** should be liberated of any shackles, as FLOOD advises (1989).

"b) **Design flexibility** should be maximized. **Design** should be adapted to cultural varieties; increase participation; allow for a global conception in which similarities, **differences** and **conflicts** could be studied; represent a planetary vision vs. chauvinistic thinking.

"c) **Design** should take into account the **complexity** of systems, conceiving their **elements** as pervasive and their **limits** as **fuzzy**.

"d) Integrated **design** of educational systems is important. But it is convenient to see that there are many possibilities of **synthesis** and **integration** and that some of them are preferable to others.

"e) Experimentation is vital in designing educational systems. A **design** that appears intellectually flawless could fail totally when implemented. Failures, however, are ways of learning to make better **designs**"

Moreover:

"In our complex world, education should cover all the main fields of human thinking and acting. Philosophy, Natural and Human Sciences, Arts, Axiology, Methodology, Technology, Manual skills, Physical fitness and Ludic activities. The different fields should be conceived as parts of a **network structure** that envelops human existence" (pers. comm.)

As a result, it could be said that systemic education cannot be taught. It must be learned and practiced in **community** by all **stakeholders**.

1024

EFFECT (Critical)

→ Critical effect

1025

EFFECT (Delayed) ^{1) - 2)}

An effect that becomes apparent only after a very long **time**.

The existence of delayed effects is generally well perceived ("The last straw that broke the camel's back"), but nonetheless nearly always unperceived and unpredicted... and when predicted, mostly met with wide skepticism.

These effects tend to be **catastrophic**, for the following reasons:

- They generally result of a slow **accumulation** of very small and scantily visible effects at a **time scale** so long that it escapes the common **observer's** attention;
- They generally result in violent and very sudden **discontinuities** ("**catastrophes**");
- Their mostly show up at a **macro- or mega-level** in **time** and frequently catch their victims in a state of total unpreparedness, because they are so difficult to **forecast**.
- This **unpredictability** is compounded by the fact that they frequently lead to global **instability** and **chaotic behavior**.

Delayed effects are universal in **complex systems**:

- In physical systems: Earthquakes, floods, great forest fires, volcanic eruptions:
- In **living systems**: epidemics, strokes, infarcts
- In economic systems: bankruptcies, market crashes
- In social systems: civil wars, revolutions

Delayed effects seem to be closely related to **phase transitions**, **giant fluctuations** and **chaos**. They frequently lead to **irreversible changes**.

The most dangerous delayed effects are the most delayed ones, generally related to not very obvious **mega-trends**. The closer study of delayed effects could lead to a "science of potential dangers" and better **risks evaluations**.

→ **Cyndinics**

1026

EFFECT (Position)

→ **Positional value**

1027

EFFECTIVENESS ¹⁾

The production at the least possible **cost**, by a **process** or **behavior**, of the expected or desired result.

To maintain effectiveness, it may be necessary to modify the **process** or **behavior**. Effectiveness is thus at a higher **level of control** or **management** than **efficiency**.

1028

EFFECTOR ²⁾

The device through which a system becomes able to act on its **environment**. (Sometimes called "actuator" - J. MILSUM, 1968, p.41)

The effector is the last link indispensable for the working of the **regulator**. It must be able to receive and interpret or understand the **messages** sent by the **adjustor** and to translate them to specific corrective action (A. LOTKA, 1956).

P. VENDRYES has shown that, to be able to operate, an effector must have sufficient qualitative and quantitative **reserves** (usable internal **resources**) at its disposal (1942).

1029

EFFECTS (Herd)

→ **Herd effects**

1030

EFFECTS (Law of) ²⁾

Other things being equal, **connections** grow stronger if they issue in satisfying states of affairs" (As adapted by E.von GLASERSFELD, 1988, p.224)

This law was enounced by E. L. THORNDIKE in 1911 and was very influential in behavioral psychology, as well as PAVLOV's conditioning, with which it can be compared.

The law is akin to the **Hebb's rule**, which is however less radical, and at the same time more precise.

THORNDIKE himself explained his law as follows: "Of several **responses** made to the same **situation**, those which are accompanied or closely followed by satisfaction to the animal will, other things being equal, be more firmly connected with the **situation**, so that, when it recurs, they will be more likely to recur: those which are accompanied or closely followed by discomfort... will, other things being equal, have their **connections** with that situation weakened, so that, when it recurs, they will be less likely to occur. The greater the satisfaction or discomfort, the greater the strengthening or weakening of the bond"

Thorndike duly acknowledges that "... the phrases "result in satisfaction" and "result in discomfort", need further definition, and the "other things" that are to be "equal" need comment...

"By a satisfying state of affairs is meant one which the animal does nothing to avoid, often doing things to attain and preserve it. By a discomforting or annoying state of affairs is meant one which the animal commonly avoids or abandons".

An important comment of THORNDIKE is that: "The satisfying and annoying are not synonymous with favorable or unfavorable to the life of either the animal or the species. Many animals are satisfied by deleterious conditions. Excitement, overeating, and alcoholic intoxication are, for instance, three very common and very potent satisfiers of man".

On the other hand: "Conditions useful to the life of the species in moderation are often satisfying far beyond their useful point; many conditions of great utility to the life of the species do not satisfy and may even annoy its members" (1911, chapter 6).

Moreover, THORNDIKE hypothesized that all these effects were results of neuronal activity at the **synaptic level**. This is impressive as one remembers that his work on these topics was published in 1911, not so long after the basic discoveries of RAMON y CAJAL (1852-1934).

1031

EFFECTS (MASS)^{1) - 2) - 4)}

The compounded **processes** or **phenomena** which appear only by **accumulation** of numerous individual **actions** or effects in a limited **space** or **time**.

Mass effects are characterized by the growing **density** of **relationships** between **elements** and/or **groups** of **elements**. They appear (sometimes quite suddenly) when a upper **density threshold** is crossed. They are generally unpredicted and even not understood, nor taken into account until they become a considerable source of trouble.

As stated by the French sociologist R. BOUDON, mass effects are generally "perverse" in the sense that the mass **process** brought about by **overcrowding**, leads to **overburdening** or **overload** and hinders or impedes individual **actions**. Urban traffic congestion is a good example.

1032

EFFECTS (Side)¹⁾

Unplanned results of a planned **change** in a **process** or system.

(also known as "spillover effects" (J.van GIGCH, 1978, p. 153).

Side effects are a typical result of non-systemic misunderstanding of complex issues.

They are a frequent result of **planning** based on **linear** methods, without regard to **complexity** in **processes**. Side effects are nearly always unexpected and suppressive, because they generally emerge outside of the scope of the **development** considered. They become more and more frequent with the ever wide-embracing nature of man's interventions in natural **processes**. While they are not necessarily negative, they should be as much as possible preventively monitored.

Moreover, in fact many side effects could be considered "wicked" (the french "effets pervers" of the sociologist Raymond BOUDON), because they frequently derive from apparently positive steps taken to solve or alleviate serious problems.

Some recent examples are: newly acquired resistance of pathological agents to antibiotics and of pests to pesticides; massive and unmanaged rural emigration caused by the green revolution; disastrous spills resulting of massive oceanic transportation of oil; social and urban transformations due to massive use of cars. The key word is "massive"! Many more cases could be cited and still more are undoubtedly in the making.

Such counter-intuitive **messes** are results of a partial and out of **space** and **time** context approach to the addressed **issues**

The systemic study of the complex **interactions** of any system with its **environment** – as a complex **whole** itself – should be very helpful to **forecast** and prevent such **situations**.

Side effects have enormous ethical bearings, fully described by J.van GIGCH (Ibid).

1033

EFFICACY (Self-)²⁾

A **self-referent process** that gives **meaning** and **value** to external **events**"

This definition by A. BANDURA is quoted by R. NUMMELA CAINE and M. CAINE (1994, p.80)

The **concept** is clearly related to the basic notions of **autopoiesis**.

It also reminds of J.J. GIBSON's concept of **affordance** (1966, 1986).

Creating self-efficacy in learners and trainees is surely as important as transmitting them **knowledge** or **skills**.

1034

EFFICIENCY^{1) - 2)}

"The relationship between **energy** (or material) **input** and **output** in a particular **reaction** of transaction" (H.S. FOREST, 1994, p.203).

This very general definition also applies to systemic **processes** and **outputs**.

Efficiency can be evaluated as the probability or **rate** at which a specified **output** is produced in specified conditions by some **process** applied to a specific **input**.

Efficiency **evaluation** implies some **criterion** about the **relevance** of the proposed course of **action** to the existing **situation** and, if the **action** is to be repeated, of the **stability** of the conditions observed.

Good examples are the frequently conflicting **evaluation** of efficiency in developmental projects, as for instance the uses of wetlands.

Effectiveness implies an **observer** and **actor's** viewpoint, and more specifically, presupposes efficiency.

1035

EFFICIENCY (Limits to)^{2) - 4)}

Efficiency is a somewhat questionable concept. If applied to systems functionality, it is possible to distinguish at least three different shades of **meaning**:

- Minimal efficiency, needed for the sheer **survival** of the system;
- Maximal efficiency, the system being pushed to its maximal **level** of **activity** compatible with its **survival** within the **environment** which provides it with its **inputs**. In such a condition, the system can easily cross some dangerous **instability threshold**;
- Sustainable efficiency, which guarantees that the system should be able to maintain its **activity** for long **time** through a well-balanced use of its **environmental inputs sources**.

H. ODUM gives the curious following example: "The elimination of fire from pine woods sets the stage for disastrous fires twenty years later" (1971, p.226).

This suggests that even the qualitative aspects of efficiency should be carefully considered. It also implies that **short term** efficiency may very well be incompatible with **long term** efficiency. This last observation may have an ominous **significance** for the present **hyper-efficient** use. of natural **resources** by **human systems**.

Still, **instability thresholds**, crossed because of such hyper-efficiency, may also lead to the **emergence** of more **complex systems**.

1036

EGALITARIANISM⁴⁾

A **behavior** in social systems in which everything is shared equally and selfish **behavior** is severely punished" (L. DICKS, 2000, p.33)

Egalitarianism seems to have the effect of weakening the need for individual **selection** and strengthening group selection. In this way, the **group** provides a global **adaptation** to the **environment** which results in a new type of advantage for all members: to receive help from others when needed and to benefit from more favorable general conditions of existence. This can be seen in anthills or beehives, as well as in any type of human societies.

The need to eliminate cheating in order to save solidarity explains the severity of punishment for selfish behavior. An extreme case was impalement as punishment for cattle theft in some Congolese Central African tribes.

1037

EICONICS¹⁾

A general science of the **images**.

Eiconics was proposed by K. BOULDING (1956) as a result of his inquiry into the nature of **images**. He wrote: "... in the concept of a **message-image relationship** there is a conceptual and theoretical **scheme** of remarkable unifying power. It is one important thread that seems to run through a number of different disciplines and sciences" (1961, p.148).

BOULDING's proposal did not catch on until now. However, a new **language** of ideographic **signs** worldly understandable is now progressively emerging and one also wonders if the main concepts of systemics and cybernetics could not be translated to an "eidetic" **language**, which would be highly understandable at all educational and cultural **levels**.

1038

EIDETIC ¹⁾⁵⁾

Related to perceived **images**.

According to G. BATESON (1979, p.228): "A mental **image** is eidetic if it has all the characteristics of a **percept**, specially if it is referred to a sense organ and so seems to come in from the outside".

We are of course left with the need of a more precise understanding of the connection between the "outside" and the "inside", i.e. the way the percept is transformed in a "mental image", and even what is exactly a "mental image"

1039

EIGEN ²⁾

A German word whose meaning is "Self".

The German prefix "eigen" means "own" and is now used in various composite words, all of them introduced by von FOERSTER (1976, p.93) and related to the **self-reproductive** properties of **autopoietic systems**, endowed with **organizational closure**. von FOERSTER wants to emphasize the **self-reference** nature of systemic **processes** and **functions**.

He even states in a paper in German that "Leben ist ein Eigenprozess" (1992, p.82), and adds: "A living being is a self-perpetuating, autonomous and organizationally closed being".

This basic characteristic was confirmed later on by H. MATURANA, F. VARELA and R. URIBE's biological research and simultaneously extended to psychology and sociology under the guise of **constructivist concepts**. (E.von GLASERSFELD, in P. WATZLAWICZ (Ed), 1992).

We thus have "Eigen-algorithms, Eigen-value, Eigen-behavior, Eigen-elements, Eigen-functions, Eigen-operators, Eigen-processes" and, in **communication**, "Eigen-feedbacks", which become the origin of "**conversation**" and **consensus** through progressive agreement on **perceptions**, **meanings** and **concepts**.

In all cases, "Eigen-situations" need to be carefully harmonized with their own origins (**autogenesis**) and all **transformations** and evolutive **changes**, like **adaptativeness** and **emergence** of higher **levels** of **complexity**.

1040

EIGEN-ELEMENT ^{1) - 2)}

An **object** as perceived by an **observer**, or **operator**.

The element becomes "eigen", because of the **process** of **observation**, specific of any individual **observer**. It tends moreover to become stabilized through repeated **observations**, in a specific way proper to the given **observer**. (Crf. "Hebb's rule")

R. VALLÉE extends the concept to "the case of two subjects observing each other and themselves" (1984, p.25).

1041

EIGEN-STATE ²⁾

"Closure of a certain **state** under an **operator**" (F. HEYLIGHEN, 1990b, p.500).

The same **state** repeats itself in a **cyclical** or **hypercyclical** way.

As observed by C. HENRY and L.M. ROCHA (1996, p. 543), von FOERSTER's Eigen-states are in fact **attractors**.

1042

EIGEN-TIME ²⁾

The internal **time** of a system.

Systems appear to possess a kind of internal clock, related to their internal **dissipation** of **energy**. P. WINIWARTER and C. CEMPEL write: "The **accumulation** of **dissipation energy** in the form of internal structural quanta within a limited potential leads from "birth" to "death" of the system. Time is expressed as internal time, or eigen-time, starting at 0 and ending at **breakdown b**" (1992, p.23). While these authors study basically the case of mechanical systems, the French biologist P. LECOMTE du NOUY established that each **living system** has its own biological time (1936). The BETHE **cycle** can also be considered as the Eigen-time clock of **stellar systems**.

The existence of the eigen-time implies that no **homeostatic** system can be eternal. A better **knowledge** of this topic could lead to a clearer **understanding** of the cause and nature of the characteristic **life span** of specific systems.

1043

EIGEN-VALUES ²⁾

The series of self-produced repeated and stable values that result of **recursive operations** in a **organizationally closed** system.

H.von FOERSTER, who introduced this partly German term, states: "... Eigen-values are discrete (even if the **domain** of the primary argument obs₀ is continuous)..."

"... Eigen-values represent **equilibria**, and depending upon the chosen **domain** of the primary argument, these **equilibria** may be **equilibrium values** ("fixed points"), **functional equilibria**, **operational equilibria**, **structural equilibria**, etc.

"... Eigen-values, because of their self-defining (or self-generative) nature imply **topological "closure"** ("circularity")" (1976, p.93).

Also in von FOERSTER's words: Eigen values are "**equilibria** that determine themselves through circular **processes**" (1981, p. 280). In a sense they are **attractors**.

As a result, any **observer's** view of reality is always self-constructed. In von FOERSTER's words: "**Ontologically**, Eigen-values and **objects**, and likewise, ontogenetically, stable **behavior** and the manifestations of a **subject's** "grasp" cannot be distinguished. In both cases "**objects**" appear to reside exclusively in the **subject's** own experience of his sensory-motor **coordinations**" (p.94).

Some measure of "**objectivity**" can be attained only through comparison by two or more **observers** of their respective sensory-motor **coordinations**, which may lead to a **consensus**. Such **consensus** is always liable to be revised, which gives a supplementary foundation to POPPER's falseability of theories and KUHN's **paradigm** shifts.

1044

EISENHOWER GRAPH

→ **Assumptions rating chart**

1045

EKISTICS ¹⁾²⁾⁴⁾

The science of human settlements.

Ekistics views any human settlement as a living **organism** having its own laws and, through the study of the **evolution** of human settlements from their most primitive phase to megalopolis and **ecumenopolis**, develops a **transdisciplinary** approach in order to better manage its problems.

These views were introduced by C.A. DOXIADIS, a greek architect and urbanist, from 1942 on.

The goal of ekistics is to develop a **methodology** and **models** to study any kind of human settlements, of any **size**, **location**, **population** and **biotope**, in order to draw general conclusions in each case.

Ekistics studies each settlement as a **whole**, integrating all of its **elements**.

According to DOXIADIS the five elements which compose human settlements are: nature, anthropos (man), society, shells and networks.

Ekistics includes a territorial **scale** of classification based on the respective areas of territories. The scale starts from the total habitable land area of the planet (about 136 million km² Antarctica excluded). It is based on Christaller's **hexagonal space filling** concept. The scale extends for 17 **levels**, starting from the total habitable planetary **space** to the basic unit considered to be 4 m² as a minimum requirement for an individual.

Ekistics also includes "population units": Unit 1 being the individual; Unit 2 two individuals; Unit 3 a medium family of 5 members and so on at a **logarithmic scale**. Each unit is supposed to be 7 times larger than the lesser one.

DOXIADIS also introduced the concept of "**ecumenopolis**" as the coming planetary organization through which "anthropos" is destined to cover the whole earth as a continuous system forming a universal settlement. This corresponds to the **man-planet system** as it is presently coming into existence.

→ **Biosphere; Eco-cube; Ecological model of the man-planet system; Ecology; Socio-cultural system; Socio-historic system; sociosphere; Sociotechnical macrosystem**

1046

ELABORATOR ²⁾

A natural organ or artificial device able to translate perceptive **data** collected by the **receptors**, into a **language** suitable for the systems use.

J.G. MILLER uses in a very similar sense the term "**internal transducer**".

A. LOTKA described as follows the **role** of the elaborator: "...combine and further elaborate the crude **information** furnished by the senses". He added: "The physical location and **structure** and **mode of operation** of the elaborators is much less obvious than that of the **receptors**" (1924, 1956, p.339-40). Despite 70 years of research, since 1924, this is still largely true nowadays, even if the construction of artificial **correlations devices** is now improving our **understanding** of the natural devices.

1047

ELEMENT ^{1) - 2)}

The minimal **components** of a system such as their total **set** and the global **set** of their **interrelations** form the system.

According to I.V. BLAUBERG, V.N. SADOVSKY and E.G. YUDIN: "Since the element appears as a kind of limit for a possible **decomposition** of the **object**, its own **structure** (or composition) is usually disregarded in the characterization of the system..." and, "... in general an **element** cannot be described outside its functional characteristics: from the point of view of the system's **wholeness** it is not the **substratum** of the element which is of primary importance, but what it does within a **whole**, what **functions** it performs in it" (1977, p.139).

As the concept of element is also used to denote a mathematical basic **part** of a **set**, it becomes a link toward formalized **models** of **concrete systems**. However, such **models** should better include the specific **interactions** between the elements, and still better, the **rules** defining these **interactions**.

1048

ELEMENT and the AUTOPOIETIC SYSTEM (The) ^{1) - 2) - 4)}

F. ROBB writes: "The **relationship** between the individual and the institution is **asymmetric**. The **autopoietic organization** does not depend on any particular individuals, but it does use and constrain individuals to serve its own ends. Indeed, it must turn over individuals in order to preserve itself. Such **organization** uses human lifetime and stored skills, experience and **knowledge**, simply as a **resource** to maintain its **autopoiesis**" (1990, p.396).

This **asymmetric interrelation** is also present in **living systems** in general. It suffices to replace the word "individual" by "element" or "**component**", and "institution" and "**organization**" by "system".

However, while elements are submitted to systemic **closure** in physical systems, they also remain transient in these entities.

This seems similarly to be the case in artificial systems, as for example in a plane, or a computer ("spare **parts**").

1049

ELEMENT (Frozen) ²⁾

An element in a **network**, unable of changing its **state**.

St. KAUFFMAN explains this as follows: "In (a) small sample **network**, all the elements (may be) **ruled** by **Boolean OR functions** and (be) all initially off. **Changes** cascade through the system after one element is turned on. Because of the **configuration** of the **network** and the **Boolean functions** involved, some elements freeze into the on **state**. Thereafter they will return to that **state** even if they or one of their **inputs** is altered" (1991, p.67).

This is a very interesting property, the base of what KAUFFMAN calls "**antichaos**", i.e. progressive **organization** of **random networks**. This author explains: "Why do **random networks** with two **inputs** per element exhibit such profound **order**? The basic answer seems to be that they develop a **frozen core**, or a connected mesh of elements that are effectively locked into either an active or inactive **state**. The **frozen core** creates interlinked walls of **constancy** that '**percolate**' or grow across the entire system. As a result, the system is partitioned into an unchanging **frozen core** and islands of changing elements" (p.67).

This very simple **mechanism** seems adequate for the modelization of numerous and seemingly unconnected properties of different kinds of **networks**. **Memory**, some neurotic or psychotic **states**, stable cores in **languages**, basic social **structures** could be examples.

Frozen cores, interestingly, appear also in some of CONWAY's **games of life**, by recurrent application of very simple **rules**.

1050

ELEMENT (The inside) PROBLEM ^{1) - 2)}

When included in a system, an element loses all or part of its potential for **autonomous activity**. This is a very significant feature and, moreover, one whose consideration is of utmost importance for the study of human systems.

1. Differences between a free and a binded element

a) A free element interact directly with its **environment** and does not depend to do this from other elements, with whom its **interactions** are nil or very slight.

On the contrary, the binded element depends on quite specific and repetitive **interactions** with some, or many, other elements and these **interactions** make sense and are maintained only within the **frame** of a more complex and generally **hierarchical** entity.

b) In some very special cases we may observe how free elements become more or less binded ones, as for example in the **transition** from individual to social **phase** of *Dictyostelium discoideum* (see J.T. BONNER, 1955, p.104ff, and more recently A.T. WINFREE, 1980, p.337-44).

We ourselves, as participants of ever wider **sociosystems**, possibly are engaged in a similar **transition**.

→ "**Meta-system transition**".

2. Progressive binding

Transition from free to binded is for elements, a progressive one. However, two different **situations** should be considered.

a) in the case of a new type of systems in the making (presocial **situation**, most specially in **human systems**), the element progressively replaces direct **interactions** with its **environment** by indirect ones, through new **interactive** elements and, in some cases, very complex chains of these **interactions**: We now buy bread from the baker, and have no more need to till the field, to sow, to reap, etc, etc. In this way, privileged and interconnected **interaction zones** in **space** and **time** are created and a common **boundary** or **interface** appears, made of elements specialized in **specific interactions** with the **environment**.

b) in the case of a new system, already endowed with **organizational closure**, for instance a newborn baby, there is a phase of **morphogenesis**, during which the elements become selectively interconnected within more or less precise **limits** (St. KAUFFMAN's **frozen cores**).

3. Levels of complexity in binding

In accordance with SIMON's **concept** of **hierarchical complexity**, elements generally bind at their own **level of complexity**: atoms with atoms, molecules with molecules, ants with ants and men with men.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Moreover higher **levels** of **complexity** can appear only when lower **level** building blocks of the suitable **classes** exist in sufficient numbers.

At each **superior** level of **complexity**, new potentialities appear: the more **complex system** becomes able to develop more intricate **activities**.

4. Do the element "understand" the system in which it takes part?

This question mark is of course anthropocentric. Moreover quotes are used because we do not know what could correspond to "understanding" at the molecular **level**, nor even among bees or ants.

In any case, it seems improbable that the **part** could be totally aware of the **whole** and of the significance of the **whole's activity** in **time**, still less than in **space**.

This problem is, indeed, a portentous one for mankind.

1051

ELEMENTS as COMPONENTS ¹⁾

When elements combine with each others, their individual properties become deeply modified.

An hydrogen atom when independent, possesses characteristics which become hidden and merely potential when combined within a water molecule. This last one, in turn, is modified when included in a **cell** (as a **part** of some biochemical product) and the **cell** itself, included in an **organ** acquires and loses some properties.

Such is also the case in **composite systems**: a migrant locust within a flight of millions of other locusts loses some of its individual **patterns of behavior** and acquires others, as for example a permanently defined flight orientation.

It is however in the strongly **integrated systems** that the elements are most modified, up to the point that their new characteristics become irreversible: they cannot anymore return to an independent **state**, nor survive if severed from the system.

The terms "element" and "component", while widely used as synonyms, have thus somewhat different **meanings**.

"Element" implies an overtone of basic simplicity and clearly defined individuality, which are at least partly results of the way we reduce the system to its **parts**. "Component" is characterized by its membership in the system.

1052

ELIZA ³⁾ - 5)

A computer **program** for the study of natural **language communication** between man and machine.

This **program** was created in 1966 by J. WEIZENBAUM (1976). It is able: "... to *mimic* a non-directive psychotherapist interacting with a "patient".

The following comment by M. RINGLE puts "ELIZA" in perspective (in accordance, it should be observed with WEIZENBAUM's own ironic viewpoint): "A.I. workers have often sought to build computer **simulations** which operate on superficial **behavioral similarities** to natural **intelligence**, rather than on the underlying **cognitive structures**. A good example of this is WEIZENBAUM's "ELIZA". ELIZA will, at least for a short time, give the impression of a sophisticated **semantic** analyzer-and-synthesizer. After a while, however, the impression will diminish as ELIZA repeats stock phrases in order to acquire more **syntactic informations**. In fact, ELIZA is simply a clever **syntactic** device, a "conversation-continuer" which lacks a **semantic** interpreter altogether" (1976, p.9).

In this case programmed "parrot speak" has been made clearly different from **artificial intelligence**, at least if one admits that **artificial intelligence** could be not purely **algorithmic**.

1053

ELLIOTT's WAVE ¹⁾²⁾⁵⁾

A **pattern** in the evolution of stocks prices first described by Ralph ELLIOTT, a californian accountant (after being ruined by the Wall Street crash of 1929)

Elliott discovered the existence of more or less regular patterns in the alternance of ups and downs of stock markets in general, and in most stocks in particular

While specific movements are individually **random** they seem to compose in **time** a kind of statistical or possibly chaotic **determinism**. Elliott discovery was based on **long term** graphics of stock quotations. It derived into a so-called "technical analysis of stock trends" through the study of certain characteristic patterns, which are supposed to have some forecasting usefulness.

This "chartist" method is widely described (with graphics) by J. CASTI (1990). It is completely at variance to the common financial and economic studies of stocks, which are totally ignored.

In fact, the chartists graphics seem to reflect the psychological aspects of stock trading (the famous "Bulls" and "Bears"). They present some interesting characteristics:

- The graphicated curves show sudden **trend ruptures** (in the style of R. THOM's "catastrophes")
- While all graphics are apparently highly irregular, it seems that **short-term** trends are imbricated in **medium** and **long term** trends. Possibly even these longer trends are some-

how constructed in a **cumulative** way through the shorter movements.

- This last feature seems to indicate that these curves are fractals, or at least imperfect ones
- The **self-similarity** at different time-spans could be interpreted in terms of **WEIERSTRASS renormalization group transformation**

The Elliott **wave** could also be somehow related to the **KONDRATIEFF cycle**, and even with SCHUMPETER's "creative destruction" model

Untill now, the whole subject remains ill understood and also under-researched. There is surely more in it than the generally recognized **random walk** model.

1054

EMANCIPATORY SYSTEMS APPROACH ¹⁾²⁾⁴⁾

M. JACKSON writes: "The concept of emancipation is a much contested one in **systems thinking**, as it is in social theory more generally. There are arguments about whether we should be seeking human emancipation, or individual emancipation or, indeed, whether non-human **elements** such as other species or the **environment** should be considered as well..." (2000, p. 291)

After describing a number of versions of the emancipatory **concept**, Jackson adds: "All emancipatory systems approach are suspicious of the current social order and seek to radically reform it. They see society as presently constituted, as benefiting some **groups** at the expense of other groups, which are suffering domination or discrimination".

And "Usually the **process** of emancipating the oppressed can also be seen to have benefits for the oppressors in the new social order" (Ibid)

This is of course a trend universally verified in the whole history of humanity.

Jackson proceeds thereafter, presenting various proposals, among them:

- Habermas' critical systems approach
- **Interpretive systemology**
- Freire's critical psychology
- MacIntyre and the moral community
- Capra's ecological sustainability

Most of these proposals, save possibly Capra's are quite weak in their deeper (i.e. not merely **ideological**, descriptive or **mechanistic**) description of the domination process in whatever **culture** or society of the past or the present.

Jackson's conclusion- at least provisional- is that "Emancipatory thinkers may be inviting the oppressed simply to enter into new relations of domination" (Ibid, p. 309)

Having stated what "should" be done—namely to "emancipate"—it would be necessary first to make clearer what is meant exactly by "emancipation" and secondly, what should be efficient and practical ways to reach such a desirable state.

→ **Assumptional analysis; Action theory; Awareness; Dominance; Frankfurt School; Search conferences; Social systems theory and design; Sociality; Sociobiology; Sociogenesis; Sociognosis; Sociolysis; Sociotechnical system**

1055

EMBEDDEDNESS

→ **Embedment (of which it is sometimes used as a synonym)**

1056

EMBEDMENT²⁾

The situation of a **component** or a **subsystem** within a system of higher **complexity**, to which it is subservient.

B. BANATHY writes: "...most systems embed other types (of systems)... In **complex systems** — as a rule— we find various layers of embeddedness of systems that represent several types. It is important to recognize the potential of such embeddedness and the need to approach the various embedded and embedding systems with the use of **methods** that are appropriate to the particular system type. For example, an industry based corporation may have embedded in it a large number of assembly line (rigidly **controlled** type) systems, that are embedded in several production (**deterministic** type) systems, that are embedded in corporate **management** (**purposive** type) systems. Another arrangement of embeddedness can be observed in a large research and development **organization**. Specific projects in such an **organization** operate as **deterministic** systems. Project **goals** and **objectives** are set by grant or contractual arrangements with **freedom** limited to selecting **means/methods**. Projects are clustered in **programs** that operate as **purposive systems**. and **programs cluster** in **program** areas that are of the **heuristics** type. The R&D **organization** that embeds these **program** areas behaves as a **purpose seeking system** type in constant search of new **domains** of research, new niches in the **environment**. Designing a project system that has clearly defined programmatic, financial, legal and time **boundaries** requires a **design** approach and **methods** that are very different from those that are to be used in designing or redesigning the entire R&D **organization** as a **purpose seeking system**, which has only broadly based policy guidance and rather open **program boundaries**" (1988, p.30).

NUMELLA CAINE and M. CAINE write: "... the fact is always embedded in multiple **contexts**, and a **subject** is always related to many other **issues** and **subjects**. The capacity of schools and society to optimize **learning** and realize the potential of the human **brain** depends on their capacity to deal with their **interconnectedness**." (1994)

A. ZELEZNIKAR, referring himself to **information**, writes: "... embedding is an accumulative and integrative **process** in informational sense... It is the basic principle of appropriation of **information** by **information**. By embedding, the outside or inside unconnected **information** comes into consideration by the entity which embeds" (1993, p.58).

Embedding dimension: "The number of dimensions needed to completely encompass an **attractor**" (J. CASTI, 1994, p.105).

Noninteger dimensional numbers are "strongly indicative of underlying **chaos** lurking in the **data**" (Ibid.).

Embedding (Transitive): "A **process** in which intellectual technology is employed to convert a **set** of collective **perceptions** into a **matrix model** of the **structure** of a system" (J. WARFIELD, 1989, p.298).

Such **model** "represents an intermediate product in a larger **process** aimed at developing insight into **complex systems** through the development of interpretive structural models" (Ibid.).

1057

EMBRACE

→ **Fatal embrace**

1058

EMBRYOGENESIS^{1) - 5)}

The **dynamics** of **development** of an **organism** or **organization** from its **autogenesis** to the **irreversible development** of its basic **processes** and **structures**.

This concept can be translated in a more or less **analogic** way from biology into **systemics**: any new **social system**, as for instance a new business, or institutional **organization**, or a new nation undergoes this type of original **structural** and **functional development** until it reaches a **viable state**. The latter is precisely characterized by a more or less complete dynamic **stabilization** of the critical **interrelations** between the **parts** of the new system.

1059

EMERGENCE^{1) - 2)}

1. "The spontaneous **transformation** of a **set** of **components** from a less coherent **state**, where the **space-time correlation** between them is confined to mean free **path** and mean relaxa-

tion collision times, to a more coherent **state** exhibiting novel, global, **dynamical space-time behavior**" (R. SWENSON, 1989, p.188).

2. "Any **process** whereby the **variety** and/or **constraint** of a system changes" (F. HEYLIGHEN, pers. comm.).

Emergence implies **discontinuity** and innovation in the construction of **complexity** (W. KARGL, 1991, p.579).

G. PASK, for instance described **functional** emergence as the recognition "by an external **observer**" that "a device or **agent** has acquired a new **distinction**, **concept**, **structure**" (P. CARIANI, 1993, p.28).

SWENSON comments that this new coherent **state** is: "many order of **magnitude** greater than mean free **path** and **relaxation** times; inaccessible to, not locatable in, and not reducible to the individual or summative **behavior** of the separated atomisms" (i.e. **elements** or **components**); "the spontaneous creation of a new **set** of macroscopic **constraints** that reduce accessible microstates from some initial **set** *M_n* to some much smaller subset *M_s*, to yield a new irreducible level of **dynamical space-time behavior**. By the **transformation** *M_n* to *M_s*, emergence is always a progressive, **asymmetrical** time-dependent **transformation** of **matter** away from **equilibrium**" (p.189).

Emergent systems are thus always more complex and less stable than their **components**. They derive from the appearance of an **emergent attractor**. Ch. LAVILLE's concepts about **vortexes** (1950), and recently D. McNEIL toroidal model of the system (1993a and b), suggest that such **attractors** are produced by opposing energetic **fields**.

HEYLIGHEN states: "The emergence of systems of (partially) conserved **distinctions** cannot be deduced from the properties of lower-level "microscopic" **distinctions**, but may be understood as a **process** of **self-organization**, governed by **variation** and selective retention" (1989, p.382).

J.P. CHANGEUX in turn states: "The highest **levels** (of **organization**) emerge progressively throughout biological **evolution**. They superpose and **embed** the inferior **levels**, themselves selected during former evolutive steps (1992, p.707).

HEYLIGHEN also writes: "... such a **process** will necessarily change the **identity** of the system itself. It might therefore also be called a **system transition**. This is a qualitative **change**, where a new **organization** or system appears, with properties (potential appearances) that did not exist in the old system. The more usual ("quantitative") dynamical **evolution** of a system, on the other hand, is merely a **transition** within the constrained **variety** of possible appearances, where neither **constraint** nor **variety** undergo any **change**" (Ibid).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This **concept** is quite different from SWENSON's, but closer to PRIGOGINE's. Here dynamical **evolution** (or better, **adaptation** or **accommodation**) remains in accordance with the **organizational closure** of the system, which is replaced, or at least transformed, in case of emergence.

Examples may better emphasize differences.

A running athlete **accommodates** him/herself to the effort by breathing rapidly and strongly, but only for a short time.

One who must go to live for years in some high altitude place, **adapts** permanently his/her respiratory capacity to this **change**.

The first animals who left the oceans underwent a radiative **evolution** of emergent types, changing branchial for aerial pulmonary breathing.

1060

EMERGENCE and REDUCTION ²⁾³⁾

Any good **understanding** of a **complex system** requires a well integrated understanding of the **relationships** between emergence and reduction.

Properties of a **whole** cannot make full sense if not sighted as a global **network of interactions** between **parts**, which in turn must be duly considered as such.

A very simple example is the study of water (H₂O).

Its properties are widely different from those of hydrogen and oxygen. However, the characteristics proper to these molecules (for example their electrons shells) are basic for the understanding of common (or heavy) water. This becomes still clearer when we consider for example the hydrogen atom within the HCl molecule.

It is commonly said that the whole is more than its parts.

It is however in a sense also less: as atoms enter in **combination**, they actualize potentially possible relationships, but also preclude others.

In short emergence and **reductionism** offer complementary and necessary views and it is a gross mistake to oppose them in an exclusive way.

In this 1996 paper, K. BAILEY offers important insights about the ways we should use what he calls the upward ladder (**bottom up**) and the downward ladder (**top down**).

1061

EMERGENCE BY RANDOM FLUCTUATIONS ²⁾

Any **composite system**, while endowed with **dynamic stability** at its own **macrolevel** (as being in a **state of thermodynamic equilibrium**), may undergo **random fluctuations** at a **microlevel**.

Such **fluctuations** may become amplified, by **positive feedbacks** and grow to the point of creating higher **level macrostructures** within the system. Endly, they may be stabilized by **negative feedbacks**.

The global result is a new global **behavior**, that was not initially predictable. In J.de ROSNAY words: "Each **random fluctuation** is a possibility of new **organisation**, implying a kind of **information**. When amplified by a **positive feedback**, any **fluctuation** becomes a **random variety generator**, base of any **evolution**" (1975, p.226).

It seems that **emergence** of a higher **level of complexity** is possible only in **composite systems**, wherein the **elements** possess initially a considerable degree of **autonomy** and are all quite similar. Their ordering by structuring **fluctuations** which become fixed seems to be the basic **process of organization of heterogeneous social systems**, i.e. **complex systems**. If such is the case, what ROSNAY calls "**evolution**" should be better named "**complexification**" or "**integration of complex systems**".

1062

EMERGENCE (Social) ^{2) - 4)}

The emergence of a higher **level of integration** in **complex systems** through the functional **association of heterogeneous groups of elements** of lower **complexity**.

Complex systems must by necessity be **heterogeneous**, i.e. made of various complementary and interconnected **subsystems**.

Such **subsystems** are generally composed of a great number of similar **elements**, which have common requirements for their survival. However, it is frequently useful for such **groups** to enter in **symbiosis** with other **groups** of different characteristics. This **process of association** repeats itself through a number of **complexity levels**.

It has possibly been at work from the nuclear and atomic **level** on, and is also probably currently active with the progressive **emergence** of a planetary society.

1063

EMERGENT PROPERTIES ²⁾

1. "Properties of a structural **level** in a **hierarchy** that cannot be predicted from the properties of the **components** of the antecedent **level** (R.F. FOX, 1988, p.171).

2. "a) Properties which emerge as a coarser-grained **level of resolution** is used by the **observer**.

b) Properties which are unexpected by the **observer** because of his incomplete **data set**, with regard to the **phenomenon** at hand.

c) Properties which are, in and of themselves, not derivable a priori from the **behavior** of the **parts**" (T.F.H. ALLEN & T.B. STARR, 1982, p.267).

A good example of emergent property can be found in a system's **autonomy**. N. PEGUIRON describes the following very simple **situation**: "Let us consider an elemental electrical circuit made up from a relay and two switches: the first normally open serves to start the current within the coil of the relay, but it can be seen that this action is conserved when one stops to press the switch; the second one, normally shut, has the opposite effect, but the same property. This very simple circuit presents the property to memorize the last performed commands however this memorization property does not belong to any of the **elements**. As long as the coils, the contacts and the switches are separately studied, it is not possible to understand, nor to predict the global property of memorization. This property is said to be emergent because it is found neither in the **components** of the system, nor in their assembled **state**" (1989, p.9).

It appears only when the system is connected functionally with its **environment**, the grid.

Numerous other examples of emergent properties can be given, as for example:

- life, in relation to macromolecules
- **consciousness** as a result of numerous **interconnexions** between neurons
- a working car, as a meaningful and functional assembly of **parts**.

Water as a liquid, while its **parts**, hydrogen and oxygen are both gases in their elemental state

1064

EMERGENT SYSTEM (Properties of the) ¹⁾

A WILDEN enumerates the following properties, as characteristics of any emergent system:

- An increased **adaptive range**
- An increased **viability**
- An increased **variety (complexity)**
- Structural innovations
- A new organizational **order**
- The shaping of modified **subsystems** (later on)
- An enhanced **selectivity**
- Changes in **adaptive order** and **learning**
- An increased mnemonic capacity
- More varied **simulations** possibilities
- Increased opportunities for changing **goals**
- An increase of the systems **sensibility to noise**"

"The **2nd. order negative feedback** under the guise of emergence, implies thus a recodification or **renormalization**, in the sense of restructuration" (1972, p.62).

1065

EMERGENTISM (Rational)³⁾

"The philosophy that combines an acknowledgment of **emergence** with the thesis that **emergence** is explainable and predictable within bounds" (M. BUNGE, 1979, p.251).

According to BUNGE, this proposal "supercedes both atomism (though not its allegiance to science) and **holism** (though not its insistence on **emergence**)" (Ibid).

Predictability "within bounds" has probably its roots in PRIGOGINE's **emergence** through **dissipative structuration** and **bifurcations** in **systems far away from equilibrium**.

1066

EMERGY¹⁾

"The total amount of **energy** embodied in the creation of some thing or conditions, and bringing it into a certain place, **state**, and **time**".

This neologism has been introduced by H.T. ODUM. (1988, 1991)

Another definition given by D.R. TILLEY, of Environmental Engineering Department of University of Florida reads: "A system property that related all **flows** and **storage of energy**, materials and **information** to the one form of source energy required for their formation and **maintenance**" (1998, p. 178)

According to this definition, it becomes possible to use "emergy accounting as a rigorously quantitative tool for valuing and comparing the work of nature with that of humans" (Ibid)

The idea that nature is "working" and in fact leaving its products at our disposal for free is generally ignored in **economics**. As a result, we are plundering nature's **ecosystems**, without making any distinction between capital and "interest". There is a wide misunderstanding of the need to respect self-maintenance of nature as a bedrock base for the **dynamic stability** of our own socio-economic systems.

The **concept** seems very important, because in many cases a quite significant part of the **energy indirectly** used up in a productive **process** is left out of economic **evaluation**.

MACHLUP and PIMENTEL have shown that many products – particularly agricultural ones – are heavily subsidized in **energy** terms and, finally produce a clearcut **energy** deficit, i. e. do not compensate the energetic investment involved. (1977).

→ **World engine**

1067

EMPIRICAL VIEW in systemics³⁾

E. LASZLO developed a systemic view of empiricism, quite close to SINGER's, CHURCHMAN's and ACKOFF's "**experimentalism**": "Empirical **facts** lie where theory meets nature: there is no **fact** without theoretical conceptions, just as there is none without an observational content. The meeting of theory and na-

ture defines the plane of **observation** and experiment: that is the realm of **fact**" (1987, p.178).

What LASZLO calls "empirical adequacy" is thus strongly influenced by various systemic viewpoints:

- **facts** should not be isolated from **context**
- **facts** may respond to different levels of **abstraction**
- **facts** are not independent from the **observer's perceptive frames of reference**.

1068

ENACTON THEORY³⁾

A theory of **cognition** which considers it as inscribed in the body.

This theory, introduced by F. VARELA et al (1993), is influenced by Buddhist traditional psychology, and constitutes also a development of MATURANA and VARELA's concept of **auto-poiesis**. It proposes an integrated approach to the so-called "mind-body" problem, as the body is the place wherein perceptive and cognitive **mechanisms** are elaborated as subjective **cognition**.

1069

ENANTIODROMIA^{2) - 3)}

"The coexistence of opposite but complementary **processes**" (H. & L. SABELLI, 1992, p.661).

H. and L. SABELLI's **process theory** "...postulates the existence of complementary opposite **processes** of **evolution** and **involution**" (p.683).

In their view, **process theory** "expands the **second law of thermodynamics**, postulating a more general hypothesis: **processes** tend to **symmetry** – including not only the point **attractor** of **entropy**, **disorder** and rest, but also complex **attractors**, chemical **structures**, biological **organisms** etc." (1992, p.661).

According to SABELLI this term was introduced by HERACLITUS and adopted by C. JUNG.

The concept could become a framework for the complementary entropy and **negentropy** ones.

1070

ENANTIOMORPHS (or ENANTIOMERS)⁵⁾

Crystals of similar **form** but that cannot be superimposed, as one is the mirror **image** of the other.

Such a type of inverse **symmetry** – known as **chirality** seems to be a very basic feature of **organization** in systems. It was discovered by L. PASTEUR (1822-1895) (levogyre and dextrogyre crystals of tartaric acid)

Complementary enatiomorphic crystals derive polarized light either toward the left, or toward the right respectively.

The same **phenomenon** appears also in biology, as for example in the opposed **complementarity** form of the human hands. It is obviously a specific case of the general opposition of symmetry and anti-symmetry.

→ **Chirality**

1071

ENCAPSULATION²⁾

The **process** that leads to the enclosure of a number of former independent **elements** within closed **boundaries**.

Encapsulation could be considered the **process** that leads to **capsulation**, interpreted as its result. Both seem to be related to so-called **frozen structures** and the shaping of **subsystems**.

1072

ENCODER^{1) - 2)}

"The **subsystem** which alters the **code of information input** to it from other **information processing subsystems**, from a "private" **code** used internally by the system into a "public" **code** which can be interpreted by other systems in its **environment**" (J.G. MILLER, 1978, p.3).

The encoder is one of the **20 critical subsystems** in MILLER's **taxonomy of living systems**.

1073

ENCODING²⁾

The act of producing a **message** (R.L. ACKOFF & F.E. EMERY, 1972, p.190).

The **encoder** must be able to make satisfactory **correlations** between its/his/her own internal **code** and the general **communication code**, whose **rules** must be precisely defined.

These are the conditions for the efficient **transmission** of a meaningful **message**.

Accordingly some **rules** of correspondance must be defined and respected, considering distinct aspects of encoding:

- the proper modulation of some physical **phenomenon**, as light or electromagnetic pulses, or sounds as for example tomtom beating or the human voice;
- the use of some specific **language** understandable by the **receiver** as well as the sender;
- the correct **syntactical** and **semantical** use of such a **language**.

1074

ENCODING: Its limits ²⁾³⁾

M.H. BICKHAR and L. TERVEEN observe the existence of an implicit assumption according to which all **representations** have the nature of encodings. They call this assumption "encodingism" and state that any programmatic research predicted on it is doomed to distortion and ultimate failure (1996).

The basic reason of this limitation is that encodings are strictly **constrained** and cannot produce more than their intrinsic **content**.

The authors propose "Interactivism" and **connectionism** as an alternative model of **representation** and explain the foundations of an interactivist architecture in Artificial Intelligence.

1075

ENCOUNTER PATTERNS ²⁾⁴⁾

The result of the progressive ordering of multiple unplanned encounters among a great number of individuals.

It leads to the establishment of selective **behaviors** and favored routes.

Such a **behavior** can be observed among foraging ants or bees. They probably result of the superposition of:

- a general diffuse **determinism** related to the ecological setting of food sources
- an also diffuse behavioral **determinism** produced by some biological socially generative factor, in these cases, **pheromones**
- a genetic behavioral pre-conditioning in individuals. Similar factors, but at a much higher level of **complexity**, are probably at work in the construction of **neuronal networks** in the **brain** and also in human societies.

→ **Crowding effect; Dictyostelium discoideum; Order parameter; Parallel distributed processing; Stigmergy; Swarm.**

1076

ENDECHY ¹⁾

The sum of the ordered part and the disordered part of the internal **energy** of a system.

This concept has been introduced by J.F. SCHOUTEN (1953, p.199-204). It can be considered as "a measure of the *a priori* possible configurations of the **parameters** of the system under consideration" (p.202).

If we consider **open systems**, we are led to the intriguing query to find out if a *mature* system would still be able to better the ratio **order/disorder** once stabilized, and, if so, how, at what **cost** and with which results.

1077

ENDOGENOUS ¹⁾

"Deriving from within the entity or system" (T.F.H. ALLEN & T.B. STARR, 1982, p.267).

1078

ENDOGENOUS DEVELOPMENT ^{1) - 2)}

The internal differentiation of a system under the limiting pressure of its **environment**.

As a system disposes of a considerable **energy flow** it may at its beginnings expand freely until it reaches spatial or energetic **limits**. It may however still be able to better its **efficiency** by a more differentiated internal **organization** and less wasteful use of its **inputs**.

1079

ENDOMORPHISM ¹⁾

"Autonomous individualization whose development rules are internal and given once and for all" (F. BAILLY, F. GAILL & R. MOSSERI, 1991, p.58).

These authors use as an example the biological development based on the genetic **template** and relate it to VARELA's **organizational closure**.

It would be interesting to scrutinize eventual possible extensions of the **concept** into psychology and sociology (the **values** system of a culture as a **template**).

1080

ENDOSTRUCTURE

→ **Exostructure and structure**

1081

ENDOSYMBIOSIS ^{1) - 2)}

"The joining of systems to form a new one" (E. JANTSCH, 1982, p.346).

Endosymbiosis seems to be a fundamental evolutive feature through the acquisition of **complexity** by the complementary union of different **modules**.

E. JANTSCH states: "In endosymbiosis, ... the original **semantic** (sic) **levels** are usually maintained, giving rise to **multilevel** systems in which each **level** functions in a **semiautonomous** way. This guarantees a substantial **gain** in **complexity**" (Ibid).

This type of **process** can be observed at every **level** of **organization** in **living systems**. L. MARGULIS established in the mid-sixties the endosymbiotic origin of eucaryotic cells.

According to JANTSCH, it may even be possible that: "... ideas may enter the endosymbiosis to form **paradigms**, **paradigms** to form world views, and so forth" (Ibid).

1082

ENERGETIC BALANCE ¹⁾

G. BATESON has observed that energy expenditure of a **living system** can be an inverse **function** of its energy **inputs**.

He gives the following significant examples: "If you kick a stone, it moves with energy which it got from your kick. If you kick a dog, it moves with the energy it got from its **metabo-**

lism. An amoeba will, for a considerable period of time, move *more* when it is hungry. Its energy expenditure is an inverse **function** of energy **input**".

In P. VENDRYES terms, the system is able to counteract environmental **perturbations** if it possesses available and qualitatively adequate **reserves** (1942).

However, these **reserves**, when used, must be regenerated in due time by sufficient **inputs**.

1083

ENERGETICS ⁵⁾

The physics of **energy** and its **transformations**.

This term now quite in disuse was proposed in the 19th century by W. RANKINE, but replaced by "**thermodynamics**", introduced by lord KELVIN. This change may be considered as infortunate, since "energetics" was less restrictive and more appropriate to a general science of **energy**.

1084

ENERGY ¹⁾

The power to bring about some **transformation**.

This definition is merely for general practical use. In fact, as G.L. FARRE states: "No one really knows what energy actually is. We only observe its **transformations**, which are represented by the laws of science, and marked by the eventual traces they leave...Whatever energy is, it is at the very least the dynamical principle of the observable **universe**" (1998b, p. 262).

We do not observe energy directly, but merely through **events**, i.e. **changes** produced by it. FARRE also notes that energy manifests itself under different aspects at different **levels** of the observable world, from the quanta to the gravitational level (Ibid).

Energy is quite an abstract concept, that we extract from perceived manifestations of **change** as for example electric, mechanical or thermic transfers, that may become or made visible through material **phenomena**.

It seems to be part of our very basic perceptive and mental **structure**, and inseparable from these other very basic notions: **time**, **space** and **matter**.

This may explain why the global concept of energy emerged only slowly, through the works of the 19th and 20th centuries thermodynamicists and of EINSTEIN.

According to D. SEIDEN and H. SABELLI: "Flowing in the direction of **time**, energy as well as **change** embodies a form, namely **unidimensional asymmetry**" or: "**Process theory** identifies... cosmic **asymmetry** as the temporal **flow** of energy" (1992, p.721).

1085

ENERGY BUDGET ¹⁾²⁾⁴⁾

The inflow of energy needed by a system for its subsistence.

Any **ecosystem**, biological or human social system depends on energy **inputs** for its **maintenance** and **dynamic stability** (J.P. COLLINS et al, 2000, p. 416-25).

Stable energy **inputs** allow for stable energy **dissipation** by the system (Prigogine's Principle of **minimum entropy production**).

Any system starved of energy **inputs** and devoid of compensatory available **reserves** is doomed to rapid destruction.

On the contrary when a system increases its energy **inputs**, it becomes able to create more complex **processes** and **structures** through a more active energy **dissipation** and the consequent **emergence process**.

Such a **phenomenon** has dominated the evolution of mankind, particularly since the beginning of the 19th Century, to date.

However, in fact the **transformation** has been obtained through an enormous subsidy of non-renewable fossil energy supply. Should this supply dwindle in the future, subsequent **growth** and **dynamic stability** will depend on its sufficient replacement by a renewable supply, i.e. basically solar energy and its derived forms.

1086

ENERGY (Downgrading) ¹⁾

As noted by J.de ROSNAY, at first sight, "there seems to exist a contradiction between the 1st. and the 2nd. Principle (of **thermodynamics**): the first one says that heat and energy are two magnitudes of the same kind; the other that they are not, since energy downgrades **irreversibly** into an "inferior", less "noble", or of "lesser quality" energy: heat. The riddle is solved by the statistical theory. Heat is really energy. More precisely, it is a kinetic energy, resulting from the individual velocities of the molecules of a gas or from atomic vibration in solids. but, under its "heat" form, this energy is reduced to a maximally disordered **state** in which each individual movement becomes soon or later neutralized by the law of great numbers.

"Thus potential energy is ordered energy and heat is disordered energy"...

"In the first case the global movement of the molecules (in a gas for example) is apt to produce some work (move a piston). In the other case, there is an inefficient agitation "on the spot" and in every direction at the same time: the energy is there, but cannot be used" (1975, p.137).

In this last form it is sometimes called "energy".

Heat is thus dispersed energy, reduced to molecular agitation. Everyday experience proves that any use of energy finally produces heat, without exception. **Entropy** is a measure of this downgrading.

1087

ENERGY (Embodied) ¹⁾

The total **energy** that has been required – directly or indirectly – to construct a system or to produce a product.

This is a very intriguing concept. Any system, natural or constructed, is somehow a totalization of residue of former energy uses. R. CONSTANZA, (quoted by R.N. ADAMS) gives the following example: "... the energy embodied in an automobile includes the energy consumed directly in the manufacturing plant plus all the energy consumed indirectly to produce the other **inputs** to auto manufacturing... etc." (CONSTANZA, 1981, p.119).

The real final energy balance and rentability of nuclear power has also been questioned, because of the similar omission of "upstream" energy **costs**.

Even the energy consumed by the **process** of scientific and technical research should be accounted for in the global energy **cost** of products.

D. PIMENTEL, who applied energy accounting to agriculture, showed that real energy **costs** of industrial agriculture are rarely if ever recuperated in the energy value of the final products (1977).

Still another aspect is the omission in the final **cost** of replacing lost patrimonial value, as is the case, for instance of the use of non-replanted felled forests.

As to natural systems, the appearance of the **GAIA** concept shows a nascent conscience of the embodied energy value in natural **environments**, as a long term totalization during the whole **process of evolution** towards **complexity**.

1088

ENERGY FLOW ^{1) – 5)}

"The one way passage (**transfer**) of energy through an **ecosystem**, including the way in which energy is converted and used at each trophic (food) **level**..." (UNESCO – UNEP Glossary, 1983, p.11).

1089

ENERGY FLOW (Principle of maximum) ^{1) – 2)}

"The physical **configurations** of the **organism** and the organic world as a **whole** are determined by the requirement of maximizing the **rate** of energy exchanges within the **organ-**

isms and between them" (N. RASHEVSKY, 1956, p.124).

This principle was originally stated by A. LOTKA in 1924, (1956, p.357).

LOTKA elaborates the concept of "coupled energy transformers". He explains that two or more systems, coupled "in cascade" become able to use a whole **range** of *differences* of energetic **levels** quite better than anyone of them separately, in view that each one, due to its proper characteristics, is only able to use a certain specific type of energy at a specific **level**.

According to LOTKA, the green plants and the animals, being globally coupled, constitute a kind of "**world engine**" *globally* able to use a greater part of the sun's **energy**. The price that they pay for this is that the global engine "...spends all its work feeding itself and keeping itself in repair, so that no balance is left over for any imaginable residual purpose. Still it accomplishes one very remarkable thing; it *improves* itself at it goes along, if we may employ this term to describe those progressive **changes** in its composition and construction which constitute the **evolution** of the system" (p.335).

The "world engine" thus progresses towards *global efficiency*, which, by the way, makes it altogether an **entropy** accelerator, *similarly global*. Such a **model** offers, somewhat unexpectedly, a base for the idea that the planet constitutes a coherent global system, at the same time evolutive and **autogenetic**, in conformity with J. LOVELOCK's "**GAIA**" concept.

This is confirmed by R. MARGALEF's discovery that the flow of energy is from the less to the more organized systems in a global **ecosystem** (1982)

→ **Saint Matthew's Principle**

Finally, LOTKA's law has been wholly confirmed by PRIGOGINE's **thermodynamics of systems faraway from equilibrium**, in which emergent **complexity** may appear through **dissipative transformation** of energy into **structures**, particularly in those systems already most highly organized.

PRIGOGINE and ALLEN moreover consider that LOTKA's law "corresponds to the **evolution** of western societies in a situation where **energy resource** stocks were not a limiting factor"... As a result "LOTKA's law finds its natural interpretation in a succession of **structural instabilities** under these conditions" (1978, p.76-7).

However, excessive energy **flows**, in particular sudden **wave** shocks, can become destructive. ODUM gives as examples the melting of insulation wires or the violent release of strong thermal winds during a forest fire.

1090

ENERGY LAW (Darwin – Lotka)^{1) – 2)}

"Whenever it is necessary to transform and restore the greatest amount of energy at the fastest possible rate, 50 percent of it must go into the drain" (as stated by H.T. ODUM, 1971, p.31).

LOTKA himself wrote: "The discharge of a portion of the energy from the **source** into a **sink** is practised, not designedly because any useful **purpose** is served thereby, but unavoidably because, in the case of all forms of heat engines, the **second law of thermodynamics** inexorably demands this payment of a tax to nature, as it were" (p.326).

Of course, biological **organisms**, and still more so human societies are "forms of heat engines"... and must pay the tax.

1091

ENERGY NETWORK²⁾

The pathways and **circuits** covered by an **energy flow** in a system or **set** of systems.

The **concept** has been introduced by H. ODUM (1971).

As explained earlier by A. LOTKA high quality energy entering a **set** of interconnected systems becomes degraded by **stages**, while part of it may be recycled in some sections. As stated by R.N. ADAMS: "There is an **energy cost** of every **activity**, act, and **event**" (1988, p.35).

ODUM proposed "energy network diagrams" as a **representation** of energy networks: "**Flows** of energy move from the **sources**, usually drawn on the left along pathways lines to the right. We refer to these **flows** as moving from upstream to downstream when they move from **source** towards **sink**. In **energy circuit language**, the simple arrow is used to indicate the direction of the driving force". ODUM created a number of graphic **symbols** to describe the various **transformations** incurred by the **energy flow**: **Source**, passive **storage**, heat **sink**, potential generating work, cycling **receptor** (or, **module**), **work gate**, **self maintenance**, **switch**, **transaction** constant, **gain amplifier**, **active impedance**, one way valve and **adding junction** (p.37-38).

1092

ENERGY PULSE²⁾

The propagation sequence of an **energy input** from one **compartment** or **subsystem** to another, throughout the whole system.

H. ODUM who introduces the concept writes: "If the **energy** arrives with repeating pulses, a train of transient peaks keeps repeating. Depending on the resistances, capacitances, and **time delays** introduced, the system's pulse

may be **damped** out downstreams or reinforced to produce an **oscillation**. Thus, **populations**, economies, and radio **networks** may oscillate or be smoothed" (1971, p.261).

1093

ENFOLDMENT¹⁾

The inclusion of local **order** within global **order**.

The **concept** has been proposed by D. BOHM, who also uses the term "implicate **order**". It is related to his concept of **holonomy**, i.e. the law of the **whole** (1980, p.156).

Through the property of **self-similarity**, local **order** may reflect global **order** and vice-versa. This is the basic property of **holography**.

D. BOHM and F.D. PEAT write: "This global property of enfoldment of **information** and detail has something in common with both **fractal** and **FOURIER orders**" (1987, p.175).

We should also mention **WEIERSTRASS' re-normalization** equation.

Enfolded order can however be unfolded, by describing the **interactions** between aspects in the system (p.156 and 184).

1094

ENGRAM⁵⁾

1) Trace left in the **brain** by a past **event** (French Robert Dictionary)

2) The neurological **change** in the **brain** that occurs during the **process** of memory creation (J. BRYANT, 1991, p. 114)

The American Heritage Dictionary (Amer. Her. Dict.) defines the engram as "a persistent protoplasmic alteration hypothesized to occur on **stimulation** of living **neural** tissue and to account for **memory**"

Interestingly BRYANT comments that: "...since the histological details of most human brains vary among one another in many ways which are not due to **learning**, it seems likely that the engram which represents a certain bit of **information** in one individual may be quite different from the engram that represents the same **bit** of information in some other individual. Thus if two people have knowledge of the "same **fact**", we should not therefore assume that they possess identical engrams, but rather that there exists a specific **correspondence** between certain **neural networks** of the two brains" (p. 114) Let us hope so!

→ **Memory; Perception; Representation**

1095

ENRICHMENT⁵⁾

In an ecological sense, an excessive increase of some **input** in an **ecosystem**.

According to S. REICE, "Enrichment **events** often constitute **disturbances**... (or) can be viewed as the indirect cause of the **disturbance**" (1994, p.428).

This is for example the case of a lake's eutrophication due to a considerable surfeit of nutrients.

More generally, in any system the excessive supply of some **input** creates a disbalance conducive to **disturbance**.

1096

ENTAILMENT³⁾

1. A necessary and predetermined **order** of succession in logical argument or between **facts**.

2. "A necessarily included (or implied) accompaniment, such as an antecedent, constituent, adjunct or consequent" (D. Mc NEIL, 1995, pers. comm.).

Entailment, as first defined, is closely related to **determinism**, but does not have an absolute predictive value in complex **situations**.

Mc NEIL's definition emphasizes a more **syn-tactic** viewpoint, not necessarily opposed to the first one.

1097

ENTAILMENT MESH¹⁾³⁾

The internal **structure** of a field of **knowledge**.

According to G. PASK, as quoted by R. GLANVILLE in "Beyond the **boundaries**" (1979), this type of structure is circular. It is however not static. For example, EINSTEIN's relativity embeds Newtonian mechanics.

Knowledge is acquired and becomes structured within such entailment meshes. Even something as basic as **learning** to walk implies the structuration of an entailment mesh (R. GLANVILLE, 1978 a)

1098

ENTANGLEMENT¹⁾²⁾

A mode of **interconnections** between **elements** which is confusing.

Entangled **relationships** are difficult to understand. They may even imply functional contradictions or **incompatibilities**.

Entanglement **situations** may appear for example, in political and administrative systems when the proliferation of subsystems and **sub-structures** is not adequately controlled. In such cases the **efficiency** of the system as a whole may be seriously impaired and the system could even be self-destroying

1099

ENTELECHY^{3) – 5)}

A supposed **vital force** driving a **living system** toward self-fulfillment.

Originally, for ARISTOTLE, entelechy was the mode of being of the completely realized **structure** of something, i.e. the result of the actualization of its potentialities.

This quite abstract notion was re-introduced as a kind of conceptual crutch by H. DRIESCH, unable to otherways understand some biological experiments, as for instance that a sea urchin egg, segmented in two parts, was able to produce two perfectly formed urchins.

DRIESCH vitalism was never admitted by many biologists and a protracted debate between **vitalists** and **mechanicists** ensued. Finally, it became apparent to L.von BERTALANFY and J. WOODGER, creators of **organismic** biology, that the conceptual deficit corresponded to our lack of good **models** of organized **complexity**.

Overtones of Aristotle's entelechy seem perceptible also in some very recent physical theories, as D. BOHM's **implicate order**, and the concept of decoherence in microphysics, and Prigogine's **emergence** through **dissipative structuration**.

In metaphorical terms the "real" world is starting to appear somewhat similar to the fading smile of Lewis Carroll's Cheshire cat.

In the same vein, F. CAPRA refers himself to Goethe: "Each creature is but a patterned gradation (Schaffierung) of one great harmonious whole" (1997, p. 21)

Capra also notes further on that the classical aristotelian concept of entelechy "as a **process** of self-regulation", was "postulated by DRIESCH (as) a separate entity, acting on the physical system without being part of it" (ibid. p. 26)

This typically mechanistic view, combined with the need for a "deus ex-machina" was later on rejected by **organismic biology**, which somehow went back to Aristotle's concept.

1100

ENTHALPY⁵⁾

"A measure of the total thermal **energy**, including the **changes** of **states**, included into a kilo or a mole of **matter**" (D. DUBOIS, 1987, p.62).

DUBOIS writes: "...thermal **energy** is the only form of **energy**, whose energetic value remains absolutely constant during its **flow** by conduction in **stationary regime**. ...thermal **energy** is the only one which is totally retained through a heat transfer because...it is the lowest of all possible forms"(p.64).

In some chemical reactions, energy in the form of heat is released (exothermic reactions, f. ex. **explosive processes**). In others, so-called "**activation energy**" must be added to initiate and sustain the reaction (endothermic reaction).

G. DYER emphasizes the role of **catalysts** in this last type of reactions: "**Catalysts** work in various ways, but their purpose is always the same - to reduce the **activation energy**. Using

a catalyst will allow a reaction to proceed with lower **energy input**" (1996, p.47).

DYER uses the enthalpy and **catalysts models** as **metaphors** for psychological reactions in small **design groups**, whose **dynamics** must be activated and can be much favored by a **catalyst**, in this case a spirit of free exchange and collaboration (ibid).

The considerable increase of enthalpy in man-managed physico-chemical systems during the last 150 years is closely related to the sociological **chain reactions** that we witnessed during this century.

→ **Entropy production (Theorem of)**

1101

ENTIFICATION¹⁾

"The discontinuous "moment" when a **nonlinearity** comes into being, as an empirically traceable **space-time entity**, defined by the circular relations of its atomisms" (R. SWENSON, 1989, p.189).

This concept is a dynamic derivate of R.W. GERARD's "entitiation" (see hereafter).

By "atomisms" SWENSON means "**elements**" or "**components**". As to the "circular relations", we may suppose that it refers to the **organization closure** that must coalesce at that critical moment.

Entification is an **emergence phenomenon**. According to F. ROBB: "From the macroscopic view it represents the coming into being of a new "entity", and from the microscopic view it is seen as a new **environment** with a new **set** of **constraints**" (1990, p.391).

1102

ENTITATION¹⁾

"The recognition or discovery of an entity that can be studied as a system" (after R.W. GERARD, 1964, p.120).

For GERARD, a system is "an **element** sufficiently **whole** and independent and internally organized to deserve separate study". Moreover he writes: "This qualitative recognition of the important systems... is far more important than their **measurement**. Entitation must precede quantitation; only when the right things have been found to measure are **measurements worthwhile**" (ibid).

For R. THOM any entity is *recognized* through its **form**. He adds however that "... for living beings, **form** is not limited to external **form**... it is also the **form** of all the internal **organs**... an internal **form** that somehow prolongs the external one". He observes that internal **form** "in embryology, is constructed continuously from the external **form**" (1991, p.115).

1103

ENTITY¹⁾²⁾³⁾

A discreet unit

In English (and in Spanish) this word corresponds generally to a well defined **object** or **organization**, clearly distinguished from any other. Its **meaning** is thus close to that of system.

In French and German (Dasein) it has a more abstract and even **ontological** meaning, closely related to existence in itself.

Of course, any pinpointing of an "entity" is made by an **observer** within specific conditions and **intentionality**

→ **Entification; Entitation**

1104

ENTITY (Reference)

→ **Stigmergy**

1105

ENTRAINMENT^{2) - 5)}

"A locking together of **frequencies**" (A.T. WINFREE, 1980, p.114).

This **phenomenon** corresponds to the **behavior** of two or more **oscillators** in **process** of **coupling**. The **oscillators** may be electrical, physical (clocks), chemical (malonic acid reaction), biological (organic functions) or social (**dictyostelium discoideum** congregation, fireflies forming **swarms** and, probably, homogenization of some characteristics in human **groups**).

Entrainment is thus a **process** of **self-organization**. It can be **topologically** modeled (R.A. ABRAHAM & C.D. SHAW, 1988, p.560).

WINFREE explains that entrainment does not necessarily implies "... a stable **relationship**, let alone... **synchrony**" (ibid).

Entrainment is not possible "... if the **periods** are too unequal or the mutual influence is too faint" (ibid).

Mutual influence obviously implies mutual **perception** through some mode of **communication**. In S. STROGATZ and I. STEWART words: "If their **interconnections** are too weak, the **oscillators** will be unable to achieve **synchrony**" (or an existing **synchrony** will be destroyed) (1993). This was already shown by Chr. HUYGHENS, with his classical experiment on **synchronic correlation** of two clocks.

For an experimental device that demonstrates entrainment see W. GARVER and F. MOSS "electronic fireflies" (1993, p.94).

1106

ENTRANCE¹⁾

Any opening or **gate** in the **boundary** or a system that allows **inputs** in a selective way.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

In French, the word "entrée" is unfortunately very generally also used in the meaning of **input**. This obscures the meaning of "entrée" as an opening in the **boundary**. The same confusion is also creeping into Spanish. The same problem exists with "sortie", i.e. **exit**, but also **output**.

→ Entry

1107

ENTROPIC DRIFT^{1) - 2)}

A natural tendency in complexes of associated systems to the compensation of unbalances. (after St. BEER, 1968, p.355).

For example, in an **ecosystem**, the unordinate **growth** of one species becomes quickly checked by some destructive countervailing factor. St. BEER gives the example of the potential fantastic propagation of aphids which, if unchecked, would produce 822.000.000 tons of aphids in one summer (New York Academy of Sciences). However, this "... does not happen... the **variety** generation that is the procreation power of the aphids is absorbed within the **ecosystem** by **homeostasis**". Even so, and notwithstanding the non-existence of any "controller", "... the **process** of massive retrenchment of an animal **population** (does not) misfire to the extent of annihilating the entire species" (ibid).

In effect, entropic drift tends to maintain global **homeostasis**, i.e. is a factor of **order**.

Unfortunately, man seems to have the power to check this re-equilibration **process**, and at least until now, seems also to be unaware of the kind of potentially **runaway situations** this may **trigger**.

1108

ENTROPY^{1) - 5)}

1) "The amount of **disorder** in a system, which by the **2nd law of thermodynamics** will tend to increase unless the system is open to receive **negentropy**, which is **information**" (J.Z. YOUNG, 1978, p.292).

2) "Abstract quantity, which characterizes the **disorder** of positions, velocities or other **variables** of particles in a large system" (R. FIVAZ, 1991, p.31).

We may distinguish statistical entropy, which measures disordered **dispersion**, and **thermodynamic** entropy which corresponds to the degree of degradation of **energy**, i.e. measures its uselessness to produce some work.

The maximum entropy in a system corresponds to the complete disappearance of **energy** potentials, i.e. the final disappearance of any **order**, in which case the system ceases to be a system.

YOUNG's assimilation of **negentropy** with **information** is not universally accepted. The **negentropy** concept itself has been much debated as to its real significance.

R. FIVAZ explains: "... (entropy) is measured by the logarithm of the number of distinct **configurations** realized by permutations between all possible values of these **variables**" (ibid).

Entropy is basically a *relational* notion which reflects the **irreversible** degradation of **energy**, through its **transformations**. The tendency of entropy is to increase monotonically and to reach a maximum as the (ideally **isolated**) **system** reaches its final **equilibrium** state.

I. PRIGOGINE writes: "As is well-known the basic importance of the **second law (of thermodynamics)** in the context of physical **evolution** was clearly recognized by CLAUSIUS who introduced the term "entropy" which in Greek means "*evolution*" (1973, p.561).

Entropy is originally a **thermodynamic** notion. It may be transposed to **cybernetics** and **systemics**. In this case, according to J.van GIGCH, it: "... refers to the amount of **variety** in a system, where **variety** can be interpreted as the amount of **uncertainty** prevailing in a **choice situation** with many alternatives" (1978, p.41).

In order to avoid **ambiguity**, let us remember however that:

1) **variety**, in a **structured system**, is obtained by defining **constraints** upon the **relationships** between **elements**. In this way a finite number of **choices** are possible.

2) excessive or total **constraints** reduce or destroy **variety**, as they diminish or suppress the number of **autonomous subsystems**. The number of possible **choices** tends to nil.

3) no **constraints** at all means total indefiniteness and thus the impossibility of any significant **choice**. Only in cases approaching this limit should **variety** be interpreted as entropy.

1109

ENTROPY: its interpretations¹⁾

Entropy has been interpreted in quite various ways. Already BOLTZMANN, proposed in 1870 a statistical interpretation based on the collective **behavior** of the numerous molecules in a gas. In this view increasing entropy - at least in an **isolated system** - indicates a trend toward an ever increasing and irreversible **disorder** in the system, i.e. the disappearance of all local differences in the **distribution** of the **elements**. This implies the disappearance of internal **organization**.

According to J.de ROSNAY: "The notion of entropy is extremely abstract and thus very difficult to imagine. However some do consider it as intuitive. They only refer themselves mentally to real **situations** like **disorder**, squandering, loss of **time** or **information**. but, how can one really imagine a **degraded energy**? And why such a **hierarchy** of **energies** and this degradation?...

"Thanks to the mathematical relation between **disorder** and probability, it is possible to speak of an **evolution** towards a growing entropy through one or the other of the following expressions: "When left alone, an **isolated system** tends toward a state of maximum **disorder**" or, "When left alone, an **isolated system** tends towards a **state** of greater probability".

"These equivalent expressions may be resumed in the following table:

Potential energy .	— entropy
Ordered energy .	— disordered energy (heat)
"Noble" energy ...	— degraded energy (heat)
Order ...	— disorder
Improbability...	— probability

"The notion of entropy and the one of **irreversibility**, coming from the 2nd principle, had consequences of enormous impact on our world view. By breaking the vicious circle of repetitiveness in which the ancients had enclosed themselves and by opposing to biological **evolution**, creator of **order** and **organization**, the notion of entropy did indirectly open the road to a philosophy of becoming and progress" (1975, p.137).

However, immediately thereafter ROSNAY points out that: "The image of the inexorable death of the universe, suggested by the 2nd. principle, did profoundly influence our philosophy, our morals, our worldview and even our art".

In fact, as expressed by J.L. ESPOSITO entropy can be considered as the *subjective* view of systems as considered by an **observer** and "... would be a measure of the degree of our **knowledge** of them" (1975, p.136). This is of course an extreme opinion, which nearly amounts to negate any objective reality to entropy.

Quoting L. BRILLOUIN (1959), de ROSNAY asks: "How is it possible to understand life when the whole world is directed by a law like the **2nd. principle of thermodynamics**, which points towards death and annihilation" (1971, p.138).

While these questions are far from being thoroughly answered, some scientists at least have brought forth elements of solution (SZILARD, BRILLOUIN himself, PRIGOGINE), which one may resume - by excessive simplification, admittedly - saying that a compensation seems to exist to entropic disorganization, and that it is precisely more **organization**, locally concentrated, and progressing with **time**. But the price is always paid: This **organization** seems to grow in proportion to a parallel *acceleration* of entropy's increase.

Another viewpoint is developed by C. JOSLYN, who distinguishes **thermodynamic** entropy (*S*) and statistical entropy (*H*). He writes: "**Thermodynamic** entropy is a property of cer-

tain kinds of real systems: **thermodynamic** systems. **Thermodynamic** entropy is a measured property of such systems, and is understood in a differential relation to other quantities, such as heat, work, and temperature, which are also measured on **thermodynamic** systems.

"**Thermodynamic** entropy is thus a "content-full" **concept** specific to **thermodynamic** systems. The **semantics** of **thermodynamic** entropy is necessarily deeply embedded within the body of thermal physics and it must be interpreted in the context of all of **thermodynamics**..."

One wonders however: Are there "real" systems which are not thermodynamic systems?

JOSLYN pursues: "But unlike **thermodynamic** entropy, statistical entropy is a property of a probability **distribution**, not a real system. Statistical entropy is calculated from the numerical properties of this **distribution**... Statistical entropy is thus essentially a "context-free" **concept**. Whatever interpretation of the p_i (i.e. probability **distribution**) we make, need only adhere to the axioms of probability theory" (1991, p.622-3).

1110

ENTROPY (Negative)^{1) - 5)}

"A measure of improbability or of **information**" (L.von BERTALANFFY, 1956, p.5).

BERTALANFFY comments: "... entropy is a measure of **disorder**; hence negative entropy or **information** is a measure of **order** or of **organization** since the latter, compared to distribution at **random**, is an improbable **state**. In this way **information theory** comes close to the theory of **open systems**, which may increase in **order** and **organization**, or show negative entropy. But negative entropy can be considered a measure of **decisions**, taken out of equally probable ones" (p.5).

R. ROSEN points out: "... it was considered a great insight when SCHRÖDINGER characterized the obvious persistence of spatial order in biological **organisms** as arising from their feeding on "negative entropy" (SCHRÖDINGER, 1945, quoted in ROSEN, 1960, p.267).

It must be pointed out that the concept of negative entropy has received various, not universally accepted interpretations (see hereafter).

1111

ENTROPY PRODUCTION^{1) - 4)}

It is generally assumed that "**order**" corresponds to a "diminution of entropy", through the incorporation of material, energetic and/or informative **inputs** into a system. While this may be true in the sense that the system may thus maintain its internal **organization** or even increase it by **dissipative structuration**, **global** entropy is effectively increasing.

R. SWENSON accordingly stated that: "**Order** produces entropy faster than **disorder**" (1989, p.125). Or better, more **order** produces entropy faster than less **order**.

F. ROBB explains it in the following way: "Entropy production is much accelerated when a new higher **order** entity emerges from lower **order** interaction, and, where conditions in the **field** permit. This is the preferred route to be selected for the maximization of the **rate** of entropy production. The **emergence** of a new entity **constraints** the microscopic **interactions** in the **field** whence it emerged. For a new entity of a higher **order** to emerge there must be (1) circular relations of **mutual causal processes**, (2) enough free **energy** to sustain these **processes**, and (3) the conditions in the arena of the microscopic **interactions**, its **configuration** and the presence of adjacent higher **order** entities, must allow such **processes** to proceed: there must be room for **emergence**" (1993, p.1).

If these conditions exist: "... then the emergent **entity** which can produce the maximum entropy is preferentially selected from all others afforded by the **constraints** present in the **field**" (1990, p.392).

This is perfectly coherent with PRIGOGINE's **thermodynamics of open systems faraway from equilibrium**.

These concepts seem to be the basic explicative key to human **evolution** if one considers the two following complementary aspects:

- 1) Since the appearance of man, evermore complex social forms of **organization** did emerge and this trend is constantly accelerating since about 200 years ago;
- 2) This **phenomenon** is matched at the same time by an exponentially growing use of **energy** and an also accelerating global entropization of the planetary **environment**.

One wonders if this is a **runaway process** and where it will lead us: to global disaster or to a **Meta-System Transition** (TURCHIN)?

1112

ENTROPY PRODUCTION in a system^{1) - 4) - 5)}

E. LASZLO writes: "The PRIGOGINE equation states that entropy change in a system is governed by the relative values of the terms in the equation $dS = dS_e + dS_i$, where dS_i denotes entropy change through the **input** and dS_e entropy produced through **irreversible processes** within the system. Whereas dS_e is always positive, dS_i may be positive as well as negative. If it is negative, the **dissipation function** of a system ($P = d_e/d_i$) is negative, i.e. is greater than 0. In this case the system decreases its net entropy or, correspondingly, gathers **information**" (1974, p.221).

There is thus a **thermodynamic** way to **self-organization** for **open systems**.

D. HERSHEY developed the concept of **Excess Entropy Production**. "For the living system, Excess Entropy Production diminishes with age and nears zero in the vicinity of death. For the aging corporation, a diminishing Excess Entropy Production track can signal stagnation, a general decline in organizational vitality" (1991, p.126).

This somewhat esoteric view implies that a diminishing rate of **energy** degradation for **adaptive activity** (for example **learning** capacity, organizational innovation, **creativity**) signals the beginning of **ageing** and **sclerosis** in systems.

1113

ENTROPY PRODUCTION in STEADY STATE^{2) - 5)}

When a system reaches its **steady state**, the entropy production becomes stabilized at a corresponding minimum (**Principle of PRIGOGINE**) and the **level** of entropy becomes constant. This is possible only because the system is able to transfer to its **environment** the entropy that it permanently produces.

If some **disturbance** takes place, due to a small increase or decrease of some **gradient**, the **flow** will automatically be modified in such a way as to nullify the **effects** of the **disturbance** and maintain the **steady state**.

This condition, proper to the systems in a **steady state**, may be compared with the **Principle of LE CHATELIER** in physical and chemical systems.

1114

ENTROPY PRODUCTION (Theorem of minimum)^{1) - 5)}

I. PRIGOGINE showed (1945) that a **system close to equilibrium** and in a sufficiently **stable environment**, evolves toward a **steady state** that minimizes the **dissipation of energy**.

This applies to **open systems close to equilibrium** and goes a step further than the classical law of **irreversible** increase of **entropy** in **isolated systems**.

It also seems to be the dynamic version of the **LE CHATELIER principle** of action and reaction for simple systems in **static equilibrium**.

In order to maintain their **equilibrium**, **open systems** of this type must constantly export **entropy** to their **environment**.

Minimum entropy production is corresponded by minimum **dissipation of energy**. In PRIGOGINE words: "The theorem of minimum entropy production expresses a kind of 'inertial' property of **nonequilibrium systems**. When given **boundary conditions** prevent the system from reaching thermodynamic **equilibrium** (i.e. zero entropy production) the system settles down in the **state** of least **dissipation**" (1980, p.88).

This is a stationary **state**. It allows the maintenance of an organized **state** in **nonequilibrium** conditions (but *close* to **equilibrium**, i.e. **homeostatic**, or **homeorhetic**).

Later on P. GLANSDORFF and I. PRIGOGINE considered and resolved the case of dynamic **systems far-from-equilibrium**, which are not any more able to maintain themselves in their former **steady state** and may jump to other **states** through **bifurcations**. In such a case: "... the **thermodynamic behavior** could be quite different, in fact, even opposite to that indicated by the theorem of minimum entropy production" (PRIGOGINE, 1978, p.2-7).

1115

ENTROPY (Social)

→ Social Entropy

1116

ENTROPY versus Improbability^{1) - 3)}

The apparently impossibility of any type of structuring and ordering **evolution** that seemed to result from the **2nd. principle of thermodynamics**, anguished many scientists during the first fifty years of the 20th century, as for example the French biologist P. LECOMTE DU NOUY. Biologists were the most desperate. H. SIMON, citing an article by H. JACOBSON, published as late as 1955, (JACOBSON, 1955) comments: "The essential idea in JACOBSON's **models** is that the expected **time** required for the system to reach a particular **state** is inversely proportional to the probability of the **state** - hence increases exponentially with the amount of **information (negentropy)** of the **state**."

"Following this line of argument, but not introducing the notion of **levels** and stable sub-assemblies, JACOBSON arrived at estimates of the **time** required for **evolution** so large as to make the event rather improbable. Our analysis carried through in the same way, but with attention to the **stable intermediate forms**, produces very much smaller estimates" (see the "**Hora and Tempus parable**").

SIMON demonstrated the possibility of the progressive **emergence of organization step by step**, through successive **levels of accumulation**.

This **concept** must be connected:

1) with the appearance of **dissipative structures** in systems overfed with an excessive quantity of **energy**, which push them through **instability thresholds**.

2) with the **concept of negentropy**, which, in the words of SIMON, "can be interpreted as the logarithm of the reciprocal of the probability - the "improbability".

3) the **understanding** that higher **complexity** in systems implies a higher **level** of entropy production.

1117

ENTROPY-VALUE RELATION⁵⁾

According to N. GEORGESCU-ROEGEN, "low entropy... is a *necessary* condition for a thing of value" (1971, p.282).

This is the viewpoint of an economist who equates value with usefulness. Value in this sense is necessarily an entropy based **concept** since low entropy is associated with **order** (a potential for use) or **organization** (a potential for efficient **action**), while high entropy implies uselessness.

1118

ENTRY^{1) - 5)}

The inclusion of some item in a **store**, a list or an account.

This is *not* a satisfactory systemic term in English. It is included only because in the French literature "entrée" is frequently used as a translation for "**input**", not satisfactory either.

"Entrée" means properly a "Gate" in a **boundary**.

1119

ENVELOPE²⁾

The external surface that limits the volume of **space** occupied by a system.

Differently, in mathematical terms, an envelope is a curve that is tangential to every member of a family of lines or curves.

This abstract concept (still defined in different terms by R. ACKOFF and EMERY, 1972, p.17) has been used by F. ZWICKY to describe higher **levels of integration of processes** at lower **levels (Morphogenetic worldview, 1971)**, and F. MEYER in a dynamic **meaning**, to describe acceleration in general **evolution** (1954).

In a more physical sense, close to "boundary", **composite systems**, which are continuously shifting in their composition and **form**, do not have any permanent envelope. It is also impossible in most cases, to describe an envelope for an **ecosystem** or a **human organization**.

Only quite strongly **integrated systems** may be said to have a well definable envelope, as for example the skin of an animal.

The envelope is at the same **time** a **boundary** that separates the system from its **environment** and an **interface** through which exchanges with the same (**inputs, outputs**) take place. It is sometimes **fractalized**, which makes it difficult to define its **limits**.

1120

ENVIRONMENT¹⁾

1. "The **context** in which a system exists" (1973, p.86).

B. BANATHY states: "It is composed of all the things that surround the system, and it includes everything that may affect the system and that may be affected by the system" (Ibid).

Of course, the whole universe is the environment of any system. Practically we must thus define in a more restricted way the environment of the system as those **parts** of the general environment that interact with it more or less strongly and/or permanently. However, there is a snag (or two):

a - Two different **observers** may very well have different **descriptions** of the system's environment (pursuing either the same- or a different **goal**)

b - There is never any absolute certainty that the **observer** did not forget, or be unable to register some important **part** of the environment.

An incorrect or incomplete evaluation of the environment is the main cause of most of the technological and social catastrophes engineered nowadays by ill-advised planners.

2. "Those **variables** whose **changes** affect the **organism** (system) and those **variables** which are changed by the **organism's** (systems) **behavior** (W.R. ASHBY, 1960, p.36).

A more or less equivalent definition by S. KATZ is: "... everything the nervous system may use as a source of **knowledge**" (1976, p.45).

ASHBY states: "It is thus defined in a purely functional, not a material sense" (Ibid). There are reciprocal **feedbacks** between the environment and the system. ASHBY cites STARLING, who wrote: "**Organism** and environment form a **whole** and must be viewed as such" (1960, p. 38). Unfortunately, this necessity is very frequently ignored, even by high level systems designers of the most various kinds: physicians, engineers, economists, agronomists, etc.

In the words of M. DODDS and G. JAROS "... the environment is not a neutral laboratory, but a **stakeholder** with its own needs" (pers. comm.).

This very serious problem is related to J. FOURASTIE's "Ignorance of ignorance" or to G.de ZEEUW's "**invisibility**": a part of the significant environment is not perceived.

3. "For a given system, the environment is the **set** of all **objects** a **change** in whose attributes affect the system and also those **objects** whose attributes are changed by the **behavior** of the system" (A.D. HALL & F.E. FAGEN, 1956, p.20).

While this very old (1956) definition looks quite rigid, HALL and FAGEN have it perfectly clear that "The statement above invites the natural question of when an **object** belongs to a system and when it belongs to the environment; for if an **object** reacts with a system in the way described above should it not be considered a **part** of the system? The answer is by no means definite. In a sense, a system togeth-

er with its environment makes up the **universe** of all things of interest in a given **context**. Sub-division of this **universe** into two **sets**, system and environment, can be done in many ways which are in fact quite arbitrary" (Ibid).

These comments are allowable, but their importance should not be over-emphasized: In most practical cases, it is easy to distinguish the system within its environment, mostly so when it is a strongly **integrated system**. This being the case, the only doubt is about some border **elements**.

Even **composite systems** (snowfields, locusts swarms, human masses) can be more or less easily distinguished from their environment.

Environment (Types of)

R.O. MASON distinguishes four different types of environments (for **organizations**, but it seems applicable to any type of systems):

"1. Placid, **randomized**: In the simplest type, **goals** and noxians are relatively unchanging in themselves and randomly distributed. A critical property from the **organization's** viewpoint is that there is no difference between tactics and **strategy**, and **organizations** can exist adaptively as single, and indeed quite small, units. The implication of this environment for a system is that it makes it stable and relatively unchanging..."

"2. Placid, **clustered**: (this) type is also static, but **goals** and noxians are not randomly distributed; they hang together in certain ways. Now the need arises for **strategy** as distinct from tactics. Under these conditions **organizations** grow in **size**, becoming **hierarchical** and tending towards centralized **control** and **coordination**..."

"3. Disturbed, reactive environment: (this) third type is **dynamic** rather than **static**. It consist of a **clustered** environment in which there is more than one system of the same kind, i.e. the **objects** (sic) of one **organization** are the same as, or relevant to, others like it. Such competitors seek to improve their own **chances** by hindering each other, each knowing the others are playing the same **game**... **Control** becomes more decentralized to allow (**operations**) to be conducted. On the other hand, **stability** may require a certain coming to terms between competitors.

"4. Turbulent **fields**: The fourth type is **dynamic** in a second respect, the **dynamic** properties arising not simply from the **interaction** of identifiable **component** systems but from the **field** itself... The **turbulence** results from the **complexity** and multiple character of the causal **interconnections**... At this fourth **level** the **concept** of **efficiency** is superseded by the **concepts** of survival and **effectiveness**" (1979, p.18-19).

1121

ENVIRONMENT (Active)^{1) - 2)}

That part of the environment with whom the system carries out frequent or decisive exchanges.

The whole **universe** is the environment of any system. However, from a practical viewpoint, the **effects** of most of the environment on the system (or conversely) are infinitesimal or extremely unfrequent.

The modelizer should however beware of which could be called the "still" or "silent" environment, which is related to very long term **transformation** factors. These are generally unknown or ignored, but may very well appear at any **time** in a quite unsuspected way and play havoc with the system (or offer it undreamed of opportunities). Typical cases are a volcanic eruption, or the millennial flood of a river or, in a positive sense, an unexpected scientific or technological discovery.

1122

ENVIRONMENT as a filter¹⁾

R. MARGALEF equates biological mutations with **noise** in the **information** that specify the **organization** of the **organism** through **messages**.

He quotes H. JACOBSON who writes: "Those **messages**, which pass through the **filter** (environment) with a **gain** equal to, or greater than unity cause **positive feedback** (self-sustaining continuation of the species). Those noisy **messages** which cannot pass through the **filter** (unfavorable mutations are rejected (bred out of the species) after a sufficient number of transmissions about the **loop**. Eventually the **message** takes on a character which is primarily due to the **filter**, in which the **gain** is maximized (natural **adaptation**). And the maximal **gain messages** may be vastly more complex than the original **message** (**evolution**) (1955, p.119-27).

The concept is clearly valid for any kind of environment.

1123

ENVIRONMENT (Benign)¹⁾

An environment whose activity does not force the system out of its **stability range**.

This notion has been proposed by R.N. ADAMS (1988, p.60). In a benign environment, the basic conditions for the sustainability of the system's **processes** and global **homeostasis** are always present.

1124

ENVIRONMENT (Dynamic)¹⁾

That part of the environment whose **transformations** are at the same **time scale** as the system.

H. OZBEKHAN (quoted by J.L. LEMOIGNE) writes: "... the word environment has been understood as too static. Reference is more and more made to *situations* in order to describe environments which change constantly; this expression connotes a dynamic environment, made of a conjunction of **events**" (1977, p.65).

A dynamic environment *requires adaptability* from the system. A more or less **homeostatic** environment admits more or less **homeostatic** systems. On the contrary, for an **emergent dissipative system**, as stated by R.N. ADAMS: "... a favorable environment is one that provides the necessary **resources** to enable it to continue its **dissipative process**" (1988, p.124).

It is a very serious mistake not taking into account some active **part** of a system's environment and it generally leads to uncorrect **forecasting**. This is a result of the frequently static appearance of the environment and the lack of **perception** by the modelizer of the different lengths of natural or induced **cycles**.

1125

ENVIRONMENT (Fragmented)

→ Fragmentation

1126

ENVIRONMENT FUNCTION^{2/5)}

W. POWERS states: "The **environment function** ... is what links the **action** of the **control system** back to its **perception**, through a **feedback connection**". (1995, p.7)

This means that the control system must have a permanently adjusted **knowledge** of the varying **environmental** conditions.

This is obtained through specific captors or **sensors**. For every complex system, as living **organisms**, and specially human beings, the environmental function becomes very intricate, as the desired **controls** must be multiple and simultaneous.

It becomes the entire field of neurological perception and cerebral interpretation and **integration** of very differentiated sets of **data**.

1127

ENVIRONMENT: Heterogeneity in space and/or time¹⁾

In theory, an environment can be **heterogeneous**, i.e. patchy in **space**, but constant in **time**... or, conversely, be uniform in **space**, in some specific place, but **heterogeneous** in **time**... and, of course, more or less **heterogeneous** both in **space** and **time**. (R. LEVINS, 1961, p.34).

S.R. REICE writes: "The environmental **patchiness** is based on physical and chemical **gradients** that are ubiquitous" (1994, p.427).

This ecological view can be applied as well to economic environments, for example.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Stability in **time** may allow for the **survival** of even quite narrowly adapted systems, while on the contrary the opposite demands for a great adaptive **variety**.

Growing exigences of a **population** on an environment may transform it in **time**, i.e. render it **heterogeneous**. In such cases, the **population** is creating hazards for itself.

1128

ENVIRONMENT (Perceived)^{1) - 3)}

E.von GLASERSFELD writes: "Jacob von UEXKÜLL, in his "Streifzügen durch die Umwelten von Tieren und Menschen" clearly showed that the **representation** that an **organism** builds from its environment can only be made from "raw materials", that the **organism** deals with in a way to define its own "experienced" environment" (1991, p.21).

Or, "... the observed **organism's** environment is still part of the **observer's** own experiential field" (1976, p.118). Thus, the *same* environment seen by a rabbit, or a fox, or a child or a human adult is perceived quite differently by any of them.

The same author adds: "Our sense **organs** perceive **distinctions**, and not 'objects'" (Ibid).

In any case, as stated by V. CSANYI: "The most important biological **function** of the animal **brain** and **memory** is the construction of a *dynamic model of the environment*, the continuous maintenance and **operation** of the **model**, and the use of the **data** obtained by **operation** for prediction in the interest of the **survival** and the reproduction of the animal" (1993, p.265).

According to D. MACKAY, this is the effective **meaning** of **mind** and **consciousness** (1951, p.118).

A quite serious problem is the existence of an *un-perceived* environment. This comes out very clearly in the following J.J. GIBSON's debatable statement: "The environment of animals and men is what they perceive" (1986, p.15). This is acceptable only from the viewpoint of psychology of **perception**, but should never be admitted as meaning: "What we do not perceive does not exist".

H.von FOERSTER's statement: "The **environment** contains no **information**. The environment is as it is" (1981, p. 271) makes this yet clearer. In fact, and obviously "what we do not perceive does not exist FOR US"

The **structural coupling** between the system and the environment creates or modifies the **meaning** within the system which thus becomes (better) informed, but always in function of its own **reference frame** (**operational closure**)

Finally, it is the system which somehow makes itself "informed"

1129

ENVIRONMENT (Stochastic)^{1) - 3)}

Environment whose characteristics are partially **random** for the system that depends on it.

Such a situation considerably diminishes the predictive ability of the system, which must then possess a quite higher **variety** (ASHBY), better countervailing **reserves** (VENDRYES), or a better **organizational closure** (MATURANA and VARELA).

According to M.P. SCHUTZENBERGER, in such a case: "...the optimal **strategy** is just the simple tactic of attempting to do one's best on a purely local basis" (1969, p.211). One could add... "on the basis of a short term evaluation".

The **random** character of the environment can be reduced in some cases by a better **input of information**, which can be obtained by the use of better **sensors**, captors or **depictors**. More adequate **models** are also very helpful.

A totally or excessively **random** environment would not allow for the **survival** of any system.

1130

ENVIRONMENT-SYSTEM CORRELATION¹⁾

R.L. ACKOFF defines the environment of a system as "a **set of elements** and their relevant properties which are not part of the system, but a **change** in any of which can produce a **change in the state** of the system" (1972).

He adds: "Thus a system's environment consists of all **variables** which can affect its **state**" (Ibid).

Some **variables changes** are frequent and obvious. Other are infrequent, nearly imperceptible, are or *seem* irrelevant. Such **changes**, the most difficult to detect, are also the more potentially unsettling.

The vocabulary used in the former paragraphs: "relevant, obvious, imperceptible, detect", indicates that the **distinction** between the system and its environment, as witnessed by the **observer**, is more or less arbitrary, even if some **criteria** "are better (in relation to **goals** and **means**) than others" R. VALLÉE, 1995, p.17).

The environment-system correlation also offers an interesting evolutive aspect. Starting from the simplest molecules on, the more and more **complex systems** that appeared through **time** showed a tendency to absorb a growing number of environmental **elements** and to create their own internal **organization** (endowed with **organizational closure**). As such, an "**environment**" must be protected from excessive **disturbances** from outside. The environment-system **correlation** may be variable in **time**, for example through an **evolution** from passive **adjustor** systems to more active **regulator** ones. This can be obtained by a number of features and the corresponding devices:

1. The most primitive systems adapted by simple **responses** to outside **stimuli**, as for example running away from unsuitable conditions.

2. More evolved systems created **sets** of alternate **behavior**, corresponding to a **variety** of possible environmental **disturbances**. This supposed the appearance of a kind of **storage** of previous experienced environmental **sequences**, and of a **selection** device for choosing the adequate **response** to specific **situations**. This implies at least a limited **knowledge** of the **environment's** properties. Inherited genetic **codes** store such **knowledge**, and **learning** is a way to acquire it, while **memory** is a way to store it.

3. As the system's internal **image** of its **environment** becomes more complete (which is the case for man), it becomes evermore able to **control** and to **transform** it, and even re-create it... but also at the same time and in some sense, more dependent of it. This may be dangerous for any human system if its **understanding** of its relation with its **environment** is not adequate.

→ **Reference (frame of); Variable (environmental)**

1131

EPIDEMICS¹⁾⁴⁾⁵⁾

The massive, swift and generally accelerating **propagation** of some **effect** in a **population**.

The population can be vegetal, animal or human, and is in fact a more or less dense congregation of individuals in a determined area.

The effect is generally biological (some disease, for instance). In human populations it can also be psychological (a rumor, a fad, a mode or, unfortunately a fear, a panic, some fanatical creed).

The effect is generally fed by some available **resource**, as for example a population devoid of immunological defenses or unexperienced, gullible and devoid of psychological and rational resistance.

An epidemic generally follows an evolving **curve**. It begins slowly and locally. Thereafter it starts to propagate in **space** and its **tempo** accelerates under the effects of contagion, which acts as a **positive feedback**, favored by conditions of close **proximity**.

After a period of seemingly exponential expansion, it starts to slow-down, as result of the growing elimination of the low resistance individuals. This acts as a **negative feedback** in sparser populations.

After a time, the epidemic subsides. It may disappear entirely, because it killed all (or at least nearly all) of the susceptible individuals. The pathological effect may also maintain itself marginally, as endemic in some section of a population.

Epidemic is obviously a very general **systemic process**.

→ **Explosive-implosive process; Growth; Meme; Pandemic; Percolation; Small world**

1132

EPIGENESIS¹⁾ - 2)

The progressive **structural** elaboration of a system produced by the interplay of some **rules** within a specified **environment**.

Epigenesis as a **concept** originated in biology, more than two centuries ago (K. WOLFF, 1767, as quoted by J. CASTI, 1990, p.137). "It means that *all* of the adult **organism** is present in codified, rather than actual, form in *all* fertilized eggs in *all* species... The difficulty with WOLFF's theory is that it says nothing about *how* the **set** of instructions in the fertilized egg becomes translated into the final adult **form**" (p.138).

This problem has been finally tackled in the second half of this century and seems nearing its solution.

In 1967, St. KAUFFMAN, as quoted by W. McCULLOCH, proposed that: "... a **random net** of **neurons**, each listening to two **neurons**, and each speaking to two, and the sixteen **Boolean functions** tossed into the **neurons** at **random**, would form a good **model** of epigenesis. These **nets** must exhibit recurrent **behavior** sequences called **state cycles**. KAUFFMAN found that with two **inputs** per **element**, **nets** typically do have very short stable **state cycles**, and very few **state cycles**" (1974, p.14).

This implies that such systems tend toward **organizational closure**. There is some analogy with the progressive **stabilization** of ASHBY's **homeostat**.

Moreover, epigenesis is a no-return trip. (see hereafter).

→ **Autogenesis; autopoiesis; Equipotentiality; Structuration (Dissipative); Zero-system**

1133

EPIGENETIC LANDSCAPE¹⁾ - 2)

The set of historically acquired conditions that guides further **evolution** within some defined **limits**.

C. WADDINGTON, who was a biologist, proposed this **concept** and commented: "The **process** starts there in a single valley, but this later branches into two or more, and these branches split up again and again, until they have formed a number of separate valleys corresponding to the separate **parts** of the adult animal" (1977, p.141).

"Valley" should be understood in the topological meaning of "**basin**".

St. BEER, in turn, writes: "The genetic **process**, with its **random** mutations, is nonetheless conditioned by the prior history of the species" (1968, p.367). This is also true for the **development** of any individual **living system** and for any human **organization** or **artefact**.

What is not yet quite clear is why and how this potential capacity for branching into a fully organized system becomes actualized.

However, the following quotation about St. KAUFFMAN's understanding of epigenesis (by W. McCULLOCH, 1974, p.14) throws some light upon this point: "Interpreting each **state cycle** - a stable mode of **behavior** of the **model** genetic **net** - as a distinct **cell type**, he modelled the epigenetic landscape as **flow** among the "**cell types**" induced by **random** minimal **perturbations** to a running system. He found that such systems "flow" down an epigenetic landscape to a **subset** of **cell types**, and remain trapped among them... **Simulation** proved him right in **model** genetic **nets** of anything up to 8.000 **components**, beyond which computer memory balks" (1967).

MARUYAMA's model of **deviation-amplification processes** clearly shows how the **process** closes on itself and how the system "becomes trapped".

Anyhow any **evolution** can be understood as a "funnel" open in the direction of the future: anything remains possible, but then only within the conditioning **limits** of the already stabilized **forms of organization**.

There is seemingly an **organizational closure** at the **mega-evolution level**.

1134

EPISTASIS²⁾

An adaptive **effect** obtained only when all the **components** in the **adaptive process** are present and properly working together (See HOLLAND, 1992, p.10 and 34)

The epistasis **effects** are characteristically **nonlinear**.

1135

EPISTEMOLOGY (Evolutionary)^{2/5)}

The evolutionary study of **cognition**. A. RANDRUP, commenting on the new journal "Evolution and Cognition" of the K. LORENZ Institute for Evolution and Cognition Research, Austria, writes: "The studies of evolutionary **cognitive** apparatus is a product of biological evolution" (1997, p. 69)

This opens a wide field of research in **cognitive science**.

1136

EPISTEMOLOGY (Systemic)³⁾

"The **set** of viewpoints and instruments used by ... researchers... to discover and organize **coherence**, derive consequences and connect

ideas in order to construct their inner **mappings** and to orient themselves" (W. KARGL, 1991, p.580).

KARGL's plural is symptomatic: Systemic epistemology is related to the **activity** of **observers**, and observed **observers**, comparing their views.

Similarly, in R. VALLÉE "**Epistemo-praxeology**" "...**subjectivity** is underlined, but **objectivity** is in no way excluded, where **interactions** between subjects imply **observations**, **decisions** and result in **actions** that modify the subjects themselves in a more or less significant way, according to issues. These **objectivity** perturbing **interactions**... can be reduced by efforts which become greater as the reduction is more radical. The best is to accept them, without ignoring their presence. This subjectivist epistemology cannot be separated (without an arbitrary decision) from a **praxeology** (1987, p.45-6).

KARGL and VALLÉE viewpoints are mainly **constructivist** ones. Besides coincidence, **coherence** and **connectivity** seeking are indeed quite systemic ways.

L.von BERTALANFFY considered that "The investigation of organized **wholes** of many **variables** requires new **categories** of **interaction**, **transaction**, **organization**, **teleology**, etc., with many problems arising for epistemology, mathematical **models**, and techniques. Furthermore, **perception** is not a reflection of "real things" (whatever their metaphysical status), and **knowledge** is not a simple approximation to "truth" or "**reality**". It is an **interaction** between knower and known, and is dependent on a multiplicity of factors of biological, psychological, cultural, linguistic, etc., nature... Against **reductionism** and theories declaring that **reality** is "nothing but" (a heap of physical particles, genes, reflexes, drives, or whatever the case may be), we see science as one of the "perspectives" that man with his biological, cultural and linguistic endowment and bondage has created to deal with the **universe** in which he is "thrown", or rather to which he is adapted owing to **evolution** and **history**" (1975, p.166-7).

The most significant parts of this text are probably the quotes used with "truth" and "reality", words whose absolute **meaning** is reflected upon within systemics.

See: "**Ontological skepticism or agnosticism**".

BERTALANFFY also stressed the concern of "systems philosophy" with **values**: "I do not see that these humanistic aspects can be evaded if **general system theory** is not to be limited to a restructured and fractional vision.

"Thus there is indeed a great and perhaps puzzling multiplicity of **approaches** and "trends" in **general system theory**. This is

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

understandably uncomfortable to those who want a neat formalism, e.g. the textbook writer and the dogmatist" (p.167).

Accordingly T. SANDOZ writes: "Systemic epistemology supposes not only a new way of seeing problems or **modelling** systems properties, but another "culture". In fact, real-life **problems, actions and methodological** issues have to be developed together (**co-evolve**). In other terms, **systems science**, with the help of **constructivist** philosophy, should propose a new world of questions (what G. BATESON called a 3rd order **change**) and not only more pertinent **models** and formalizations" (1993, p.1543).

Systemic epistemology is thus essentially based on multiple reciprocal **relationships**. (see "**Definition**").

A typical case is the way **chaos theory** has modified the relation between the seemingly opposed concepts of **determinism**, and **randomness**. **Randomness** may mask some hidden **determinism**, and the opposite. Complementary **models** are thus admissible and frequently useful.

Systemic epistemology should also be evolutive. As, stated by D. CAMPBELL, **organisms** seek to increase their **fit** to their **environment**. (Quoted by E.von GLASERSFELD, in his paper "Konstruktion der Wirklichkeit und des Begriffs der Objektivität", 1991, p.27, in itself a **constructivist** manifest).

From another viewpoint, G. KLIR observes that systemics imply an "epistemological **hierarchy**, whose key feature "is that every system defined on some **level** in the **hierarchy** entails **knowledge** associated with all corresponding systems on lower **levels** and, at the same time, contains some **knowledge** that is not available in any of these lower systems.

"The number of **levels** in the epistemological **hierarchy** is potentially infinite. In praxis, however, only a small number of **levels** is considered" (1993, p.33).

An interesting example is J.G. MILLER's **taxonomy of living systems**, selecting 8 **levels of complexity**.

1137

EPISTEMO-PRAXEOLOGICAL CLOSURE²⁾ - 3)

Situation resulting from the "**feedback** to the **input** x of the system (**evolution** of the system and its **environment**) obtained through the **effectors** controlled by the **decisions**" (R. VALLÉE, 1990, p.40).

R. VALLÉE explains this concept as follows: "The **cybernetic system** S acquires a **knowledge** of itself and of its **environment** F by way of its **observation organs**... These **perceptions** generate **decisions** which command S 's **effectors**. These **effectors**, by their **simultaneous action upon** S itself and upon F modify the **evolution** that S and F would have undergone

without their intervention. An *indirect consequence of that perception which S obtains from itself and of its environment is thus to modify this perception*. In this sense, the system knows itself and constructs itself, and knows and constructs its **environment**" (1991, p.145-146).

VALLÉE calls this **process**: *Epistemo-praxeological cognition*. He adds that "This **co-evolution** is akin to what Heinz von FOERSTER calls "**Eigen Behavior**" (von FOERSTER, 1981, p.274), but which in this case refers only to S " (Ibid)

VALLÉE's concept, also elaborated by him in various papers as a mathematical formalism, is thus at variance with MATURANA and VARELA's **organizational closure**, as it does not readily dissociate the system from its **environment**. VALLÉE explains how his views "modify the notion of **subjectivity**" in the following terms: "In the **co-evolution**, or the **symbiosis** of two observing and acting **subjects** S_1 and S_2 , the **image** that they gather from each other... is on various **levels**: the **observation** one, the **decision** one, or more synthetically, the **action level**. But, if **subjectivity** is underlined, **objectivity** is in no way excluded. The epistemological, pragmatical and praxeological images that S_1 obtains from itself and from S_2 are determined by the **state** of S_1 and S_2 , that is only defined at a *meta-level* out of reach for S_1 and S_2 ." (1995, p.102). These views come closer to LOTKA's "**planetary engine**", LOVELOCK's "**Gaia**" and GRASSÉ's **stigmergy**.

For a complete development of the epistemo-praxeological concept, see R. VALLÉE's "Cognition et système" (1995).

A quite similar concept has been enunciated by R. MARGALEF: "When we interfere with the functioning of nature, we are converted into **parts** of the larger system, such as the experimenter is included in the experiment" (1980, p.39).

Epistemology in a systemic sense is thus in no way independent of the very progress of rational **knowledge**, which eliminates former areas of ignorance (non-rational explanations or no explanation at all), but creates new ones, as the intrusion of formerly unrecognized or non-existent **effects**.

1138

EQUIFINALITY¹⁾ - 2)

1. Property of a system able to reach a final **state** starting from different **initial conditions** and by different ways (Adapted from J.G. MILLER, 1978, p.41).

The equifinality concept was introduced by L.von BERTALANFFY (1940, p.521).

Equifinality is possibly more a seeking **behavior** than a property.

MILLER gives anyhow, on basis of the equifinality property, a new interpretation of DRIESCH's experiment of cutting an embryo of a sea urchin in two halves, each of which remains still able to produce a normal sea urchin.

Thus a **cybernetic-systemic understanding** of a general **process** replaces a vitalistic interpretation.

MILLER writes: "The obvious **purposive activities** of most **living systems**, which may have seemed to many to require a vitalistic or **teleological** interpretation, can be explained as **open-system** characteristics by means of this principle. Some **open physical systems** also have this characteristic" (p.41).

Equifinality operates by regulating **feedbacks** and becomes more efficient when the system is endowed with more **variety**.

However as noted by Stafford BEER, "death is equifinal" as a result of the **ageing process** in any **autopoietic** system, definitively unable to escape from **organizational closure** (as anyone of us).

Another shade of **meaning** is equifinality by **irreversible thermodynamic transformation** towards a **state** of maximum **entropy**: "Given the final **state** with maximal **entropy**, it is impossible to know which initial **state** led to this result" (F. HEYLIGHEN, 1989, p.366).

2. "The ability of living **organisms** to reach an initially predetermined final **state** in spite of **perturbations** in the **initial conditions** (proceeding from different initial **states** and by different routes)" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.49).

BLAUBERG et al add: "In **closed systems** their final **states** (e.g. distribution of matter concentrations) are entirely determined by the **initial states**, which is reflected in the corresponding "mechanistic" formalism" (Ibid).

Let us remember the ambiguity of the "**closed system**" model.

R. ROSEN describes equifinality as "... the stubborn tendency of a developing system to reach the same final **state** despite such experimental interventions as amputations, randomization or hybridization" (1979, p.176).

The predetermined character of the final **state** is a necessary consequence of the 2d. **Principle of thermodynamics** which prescribes an irreversible increase of **general entropy** with **time**. However (and paradoxically) **complex systems** become highly organized by creating **heterogeneous structures** through **dissipation** of growing quantities of **energy** obtained from their **environment**, but at the price of rejecting more **entropy** in this same **environment**.

This type of situations has been clarified by PRIGOGINE, within the **frame** of his **thermodynamics of irreversible systems**

1139

EQUIFINALITY PRINCIPLE¹⁾

"In **open systems**... the same final **state** may be reached from different initial conditions and in different ways" (L.von BERTALANFFY, 1956, p.4).

BERTALANFFY observes that this is not the case in **closed systems** and gives as an example the *perfect previsibility* of the movement of the planets and of their position at some t_1 moment knowing their position at t_0 . (Ibid).

Let us remember that, nowadays, this **previsibility** is not anymore considered perfect (see: **Chaos**), which does not anymore allows for the unrestricted generalization of the equifinality principle to the physical systems.

The equifinality principle, as a conceptual **model**, replaces in biology the vitalist concept proposed by the German biologist H. DRIESCH based on his experiences on the development of sea urchins embryos: "The same final result, a normal individual of the sea urchin, can develop from a complete ovum, from each half of a divided ovum, or from the fusion product of two whole ova. The same applies to embryos of many other species, including man, where identical twins are the product of the splitting of one ovum" (Ibid).

BERTALANFFY adds: "... equifinality is not a mathematical characteristic but a physical characteristic of (certain) **open systems**. It does not depend on the **structure** of the system equations but on the **meaning** of the **parameters** so that formally identical equations may apply to non-equifinal **closed systems** as well as to equifinal **open systems**. However, the equifinal case where the final **state** depends only on the **reaction** and transport **parameters**, and not on the **initial conditions**, is found only in **open systems**" (Ibid).

In spite of its evident importance, the equifinality principle presents serious interpretative difficulties. For example, the *same* system necessarily starts from one and only one initial set of conditions and while it *could* follow different **paths** for its **transformations**, it will really take one, and only one.

Let us also remember the semantic **ambiguities** concealed under the concepts of "**open**", "**closed**" and "**isolated**" system.

1140

EQUI-INITIALITY¹⁾

"The (conventional) scientific notion (applicable to "**closed systems**") that "identical" **initial conditions** will necessarily result in "identical" final **states**" (D. Mc NEIL, 1995, pers. comm.).

This neologism is basically another way to enounce the basic tenet of classical **determinism**. It is at the same time an axiom and a belief, neither entirely verifiable on **concrete sys-**

tems, since none is ever identical to any another one. The concept has been introduced by Mc NEIL as a kind of counterpoint to be compared to the **equifinality** one.

1141

EQUILIBRATION²⁾

Progressive **stabilization** of the internal **functions** of a system normally active in its specific **environment**.

This term has been introduced by J.L. LEMOIGNE who describes as follows the different types of equilibration in his **model** of "**Système général**". (i.e.: General **model** of the system):

- by **regulation**, if the system maintains a stable relation with its **environment**. This mode leads to **homeostasis**
- by programed **adaptation**, if the system's relation with its **environment** is changing. This **mode** corresponds to **homeorhesis** in a growing system.
- by recoding, a **mode** called **homeogenesis** by LEMOIGNE. Such a mode of equilibration implies probably a master **program** of **programs**.
- by structural **adaptation**, when the system itself is changing its **goals**. LEMOIGNE calls this transformation (with hyphen) and, while he does not explicit the idea, it seems to be the mode of equilibration of human **organizations**.

LEMOIGNE presents a last type of equilibration, by structural **evolution** – which he equates with **morphogenesis**, but which seems to be no equilibration at all, if it is understood as the complete recasting of the system by **dissipative structuration** due to giant **fluctuations far away from equilibrium**.

1142

EQUILIBRATION THEORY²⁾³⁾

This theory, elaborated by J. PIAGET (1975) is at the same time a biological, a psychological and a conceptual one. E.von GLASERSFELD writes: "For PIAGET, **knowledge** is adaptive insofar as it enables us to **control experience** and to maintain our **equilibrium**. I hasten to add that "equilibrium" is a **multilevel concept** that covers **survival** on the physical/biological level as well as **coherence** and non-contradictions in the conceptual sphere.

"This is one of the points where, I think, Humberto MATURANA and PIAGET are in agreement. MATURANA speaks of "effective action" – and it is easy to translate "effective **action**" into PIAGET's terms as any action that maintains or restores the actor's equilibrium" (1992, p. 24)

von Glasersfeld makes also a connection with B. POWERS' theory of **control** of **perception** (1973). Any move to counteract what Powers calls an "**error signal**" is indeed always a move towards equilibrium (Ibid)

1143

EQUILIBRIUM¹⁾

"A **state** of a system which keeps certain properties **invariant**" (G. PASK, 1961, p.114).

This is merely one of the many more or less complementary definitions that can be encountered in the literature. It is sufficiently general to include different kinds of equilibrium (see hereafter).

For PASK: "The term includes not only **static equilibria** – an object at rest – but also **dynamic equilibria** and statistical equilibria" (Ibid)... which of course are quite different **situations**.

W.R. ASHBY gave examples of three basic types of equilibrium:

"Stable equilibrium" typified by "a cube resting with one face on a horizontal surface".

"Neutral equilibrium", the case of "a sphere resting on a horizontal surface".

"Unstable equilibrium", the case of "a cone balanced on its point" (1960, p.44).

More recently K.De GREENE distinguishes four kinds of equilibria: equilibrium per se, restorable disequilibrium, **multiple equilibrium** and **nonequilibrium/far-from-equilibrium**.

He states: "The major emphasis of **system dynamics**, at least formally, is on the first two conditions. The third condition is studied by **catastrophe theory**. The fourth condition is emphasized by **dissipative-structure** theory and by **synergetics**" (1994, p.7).

Generally, equilibrium is a **state** in which a system tends to remain if no **disturbance** deflects it from the same.

Homeostatic systems (i.e. systems endowed with **dynamic equilibrium**), when disturbed, tend to return, to "bounce back" from their **stability thresholds**, through **negative feedback** and thus to remain within a well defined **stability channel**.

A system in equilibrium is "short-sighted", i.e. has no **sensitivity** to long term **trends**. Curiously enough, our own appreciation of equilibrium in systems whose duration is very large in relation to our own life-time also tends to be "short-sighted": it is very difficult for us to develop a **sensitivity** to long or very long **rhythms of change**.

Equilibrium can also be an instantaneous and transient **state** of a system submitted to a **periodic process**.

A. BOGDANOV called such variations "a dynamic equilibrium of **changes**" wherein "Preservation is always only a result of immediately equilibrating each of the appearing **changes** by another opposing **change**" (1980, p.78).

This is in fact an extension of **LE CHATELIER Principle**.

The **transition** from an unstable to a stable and definitive equilibrium reflects the **action** of some **asymptotic attractor**, which corresponds to a **gradient** characterizing the successive values of the **variable**.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

W.R. ASHBY expresses this as follows: "Given a **field**, a **state** of equilibrium is one from which the representative point does not move" (1960, p.46).

Arguably, ASHBY could have added "...any-more", since in the very next paragraph he states: "Notice that this definition, while saying what happens *at* the equilibrium **state**, does not restrict how the **lines of behavior** may run around it. They may converge into it, or diverge from it, or behave in other ways" (ibid).

Static equilibrium – and subsequent **destruction** – is anyway the final **state** of any **living system**.

1144

EQUILIBRIUM (Asymptotic)²⁾

This is the type of equilibrium toward which tends a system whose successive **states** are fully determined by the initial **energy** available to it. In such a case, the system is never able to **autonomously** leave its final equilibrium, once reached. The system responds to a punctual **asymptotic attractor**.

In a more general sense, **homeostatic** systems with **inputs of energy** also tend to asymptotic equilibrium. In this case it seems that the cause of **decay** is the originally limited capacity to assimilate **information**, resulting from their **organizational closure**. In St. BEER words: "Death is **equifinal**"!

→ "Eigen time".

1145

EQUILIBRIUM (Dynamic)²⁾

The condition of a system whose **processes** may **fluctuate** within more or less ample **limits**.

This is practically a synonym for **homeostatic equilibrium**.

1146

EQUILIBRIUM (Ergodic)²⁾

The global **state** of a system which is able to transit randomly from one specific **state** to another, within a defined **set** of possible **states**.

Ergodic equilibrium is **invariant**, as explained by G. PASK (1961, p.122), since the global **values** of the probabilities **distribution** do not change and are independent of the initial **state**.

1147

EQUILIBRIUM (Far-from)²⁾

The condition of a system undergoing ever widening **fluctuations**.

Such condition generally heralds the beginning of **dissipative structuration**, if and when an important surplus of **energy** is available. In G. NICOLIS and I. PRIGOGINE words: "... the distance from equilibrium and the **nonlinearity** may both be sources of **order** capable of driv-

ing the system to an ordered **configuration**. A highly non-trivial **connection** between **order**, **stability**, and **dissipation** appears. To indicate clearly this relation we call the ordered **configurations** that emerge beyond **instability** of the thermodynamic branch the **dissipative structures**" (1977, p.60)

Once crossed the **instability threshold**, the system's **behavior** undergoes a drastic **change**, thus described by I. PRIGOGINE: "... the **thermodynamic behavior** could be... in fact, even directly opposed that predicted by the theorem of **minimum entropy production**" (1980, p.88).

According to K.DE GREENE: "... nonequilibrium is the source of **order**; it brings **order** out of **chaos**... Far-from-equilibrium situations induce a new **coherence** among system **elements** via new **patterns of communication**" (1994, p.9).

The far-from-equilibrium condition should be clearly distinguished from the near-equilibrium one, in which the system only fluctuates moderately within narrow **limits** and remains **homeostatic**.

1148

EQUILIBRIUM (Global)^{1) - 2)}

W.R. ASHBY states: "That a whole **dynamic system** should be in equilibrium at a particular **state** it is necessary and sufficient that each **part** should be in equilibrium at that **state**, in the conditions given to it by the other **parts**" (1960, p. 79).

Of course, this is an "ideal" **state**, never practically reached by a **dynamical system**, as ASHBY himself recognizes: "Clearly at any **state** of the **whole**, if a single **part** is not at equilibrium (even though the remainder are) this **part** will change, will provide new conditions for the other **parts**, will thus start them moving again, and will thus prevent that **state** from being one of equilibrium for the **whole**. As equilibrium of the **whole** requires that all the **parts** be in equilibrium, we can say (metaphorically) that every **part** has a power of veto over the **states** of equilibrium of the **whole**" (ibid).

Practically, the **oscillations** will be permanent.

1149

EQUILIBRIUM (Homeostatic)^{1) - 2)}

A dynamic equilibrium, characterized by **oscillations** within more or less narrowly defined maxima and minima **limits**.

K. BOULDING described it as follows: "Equilibrium is simply a **dynamic process** in which the dynamic **path** of the system leads to a **reproduction** in successive **states** of some initial equilibrium **state**. "Staying the same" is simply a special case of "changing" (1972, p.68).

Homeostatic equilibrium does not allow for basic structural or functional **changes** in the system, i.e. is never evolutive, even if it is adaptive. It remains in basic accordance with the laws of classical **thermodynamics**.

L.von BERTALANFFY made the following comment: "If life, after **disturbance** from the outside, had simply returned to the so-called homeostatic equilibrium, it would never have progressed beyond the amoeba which, after all, is the best adapted creature in the world – it has survived billions of years from the primeval ocean to the present day. MICHELANGELO, implementing the precepts of psychology, should have followed his father's request and gone in the wool's trade, thus sparing himself lifelong anguish although leaving the Sistine Chapel undecorated" (1971, p.192).

1150

EQUILIBRIUM (Levels of)¹⁾

As a result of complex intertwining of different functional **cycles** in the variations of a **complex system's behavior**, different levels of equilibrium may become dominant at different moments.

K.DE GREENE states: "At any period the system hovers around an equilibrium level. Over **time**, **deviations** from equilibrium may expand or contract" (1988, p.283).

This author, who reconsiders the whole subject of **cycles**, explains that, in economic **cycles**, "KONDRATIEV identified at least three orders of equilibrium:

"1. first order equilibrium of short duration...

"2. second order equilibrium of intermediate duration...

"3. third-order equilibrium of longest (but nevertheless limited) duration" (ibid).

Short duration corresponds to more or less small and local **random** movements of quite limited **amplitude**, channelled within medium and long term trends

2d order movements are related to more permanent **trends**, while 3rd order ones are related to the most basic and general alternative conditions that the system may possibly have to adapt to.

There can be more than three levels of equilibrium.

On the other hand "short, intermediate and long duration" are defined in relation to the nature of the system. They have different **meanings** for the **growth** of some annual plant and for sequoias, for flies and for elephants.

Levels of equilibrium, described by KONDRATIEV in economic **cycles**, command undoubtedly the **dynamics** of numerous other types of systems, specially those in **homeostatic** conditions. **Transitions** from one level to another can be sudden, and thus **catastrophe** and **chaos** theories could be useful to formalize **models**.

1151

EQUILIBRIUM (Metastable)^{1) - 2)}

An equilibrium that remains stable until some **trigger element** is introduced in the system, but undergoes a sudden **change** when such **element** appears.

Such equilibria are characterized by their potential for **growth**.

A. LOTKA states: "This is a common characteristic of the **growth** of **living systems**; **growth** is initiated by a nucleus of the same species of **matter** that is added... Conversely, in the entire absence of any nucleus of a particular species of living **matter**, **growth** of that species cannot take place, even though all other conditions for such **growth** may be satisfied, even though the system may, as it were, be supersaturated with regard to that species of **matter**" (1956, p.151).

This **phenomenon** is also well known in inorganic systems (supersaturated solutions).

Sudden epidemics in **populations** that overshooted their **environmental optimum** seem to respond to the same **trigger effects**: A case may have been the so-called "Black-Death" pandemic in Europe from 1347 on.

1152

EQUILIBRIUM (Multiple)^{1) - 2)}

"An area of **catastrophe theory** in which system **behavior** can flip unexpectedly from one **attracting** equilibrium to another" (K.DE GREENE, 1988, p.286).

DE GREENE emphasizes this type of equilibrium in relation to his study of the **interconnections** of **cycles**. He states: "In **catastrophe theory** the **attractors** are static **equilibrium points**. As a **control parameter(s)** "drags along" a **behavior variable**, the system may cross a **discontinuity** or **catastrophic** point, line, or surface and jump to another equilibrium **manifold**. This **activity** illustrates multiple-equilibrium **behavior**" (1994, p.8).

Unexpected flips occur when the superposition of various **cycles** of different lengths converge unto a same point and moment, which thus comes to be an **unstability threshold**.

The **switching** from one to another equilibrium corresponds to the **switching** from one **attractor**, corresponding to one **phase**, to another one.

Multiple equilibria, far from being merely an economic **phenomenon**, constitute a general **model of behavior** of many classes of systems.

1153

EQUILIBRIUM of flows^{1) - 2)}

The result of an adequate compensation between incoming and outgoing flows in a system.

J.de ROSNAY comments: "When equilibrium is reached, a certain **level** maintains itself through **time** (... concentration of certain molecules in plasma, or state of a bank account). This particular **state** is called **steady state** and is quite different from the **static state** figured by the water **level** in some tank without **communication** with the outside".

"An unlimited number of **steady states** are possible. This is what allows an **open system** to adapt and meet the enormous **variety** of the **environment's** modifications" (1975, p.118).

1154

EQUILIBRIUM of forces²⁾

The result of the nullification in one point of two or several equal but opposed forces.

Examples are a book lying on a table or a ball in a bowl. J.de ROSNAY comments: "An equilibrium of forces is static. It can be modified only by a **discontinuous change** in the ratio of forces. A succession of such **discontinuities** may lead to a **runaway event**" (1975, p.117-18).

1155

EQUILIBRIUM (Out of)^{1) - 2)}

A condition of a system heralding an imminent **change** in its relation with its **environment**.

If it is to maintain itself, the system must be able to expend **energy** as it seeks a new **equilibrium**.

1156

EQUILIBRIUM (Punctuated)^{1) - 5)}

The enhancement by successive stages, of **fitness** of some natural or artificial species.

The concept was originally proposed by H.J. Mac GILLAVRAY and developed by S.J. GOULD and N. ELDREDGE, as a **model of evolution** by jumps (L.M.VAN VALEN, 1995, p.270).

It has now been modeled by W.D. HILLIS, on a **population** of 65.536 artificial **elements** ("Ramps" - **elements** which climb a "**fitness** ramp"), each **element** being endowed with a number of "genetic" characteristics that can freely recombine in a **network**. "Testing the **fitness** of his "ramps" against a problem in their **environment**, he showed that "their gains in **fitness** proceeded by "punctuated equilibrium" - periods of **stability** were shattered by sudden leaps in **fitness** (as if)... **evolution** had found a new power that enabled the Ramps to deal with their **environment** more effectively... When HILLIS examined the "genomes" of the Ramps during the presumably **stable period** of **equilibrium**... he found that the gene pool was actually seething with activity, setting the stage for the next leap" (S. LEVY, 1992, p.206).

Just as in **evolution** of the living, this **process** of artificial **evolution** includes first diversification ("typogenesis"), next variation within narrow **limits** ("typostasis") and finally senescence by overspecialization ("typolysis") (On typolysis in animal species, see H. DECUGIS, 1941).

Punctuated equilibrium seems thus to be a general property of **networks** composed of numerous **variable elements** in **interaction**. This could be important in economics, **management** and social sciences.

Punctuated equilibrium implies that nature can be understood as a **non-equilibrium system**.

P. BAK writes: "The **concept** of punctuated equilibrium turns out to be at the heart of the **dynamics** of **complex systems**. Large intermittent bursts have no place in **equilibrium** systems, but are ubiquitous in **history**, biology and **economics**" (1996, p.29)

1157

EQUILIBRIUM STATES²⁾

Any equilibrium is necessarily related to the specific **dynamics** of the **environment** on which it depends for its permanence or modification. According to R.N. ADAMS: "Equilibrium **structures** do not have to do anything to maintain equilibrium; the **environment** does it all" (1988, p.124).

Three different states of equilibrium are generally recognized, as exemplified by ASHBY (see "Equilibrium"):

What differs in these three different types of equilibrium is the importance of the **environmental disturbance** needed to modify the existing **state**.

From the **topological viewpoint**, the same **states** could possibly be characterized as follows:

- **stable**: immobility after **convergence** on a uni-dimensional **attractor**;
- **neutral**: indefiniteness within the **limits** of a two dimensional **attractor**;
- **unstable**: included within a **chaotic attractor**, or running toward a one dimensional **attractor**.

1158

EQUILIBRIUM (Static)^{1) - 2)}

"A **time** independent **state** of a **closed system** in which all **macroscopic** quantities are invariable and all **microscopic processes** discontinued" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.47).

These authors write: "According to the **second law of thermodynamics**, each **closed system** finally reaches a **time**- independent state of equilibrium with maximum **entropy** and minimal free **energy**" (Ibid).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

It should be better **semantics** to call "**isolated system**" this purely abstract system to which the **2nd. law of thermodynamics** applies in a rigorous way.

This type of static equilibrium is quite different from the **dynamic equilibrium**, proper to **steady states** in active **dynamic systems**.

Static equilibrium is necessary a final **state** in any system, in accordance with the **2d Law of thermodynamics**. As stated by A. KATCHALSKY, such final **states** are "memoryless", i.e. do not conserve any trace of their former functionality or organization (1971, p.60-61). They normally imply the destruction of the system and the **dispersion** of its **components**.

1159

EQUILIBRIUM (Statistical) ²⁾

G. PASK writes: "By analogy with a **state-determined system** any **Markovian system** reaches statistical equilibrium. In equilibrium it is characterized by averages h_{ij} and, regarded as an **information source**, it has a measurable **variety**. For n states, the maximum **variety** is $\text{Log}_2 n$, the **variety** of the **reference frame**, without any statistical **constraints**" (1961, p.45).

This seems to correspond to the **limits of chaotic variation** in the dynamics of **complex systems**.

1160

EQUILIBRIUM SYSTEM

→ **System (Stable)**

1161

EQUIPOTENTIALITY ^{1) - 3)}

Condition of a system that, starting from its **initial state**, may reach different **states** of **dynamic stability**.

Just like with **equifinality**, this property can never be verified in **concrete systems**, which have each one and only one adaptive sequence.

J. SINGH goes however quite farther, and in a different interpretation, when he writes that this is "the property of a system in which remaining **subsystems** can fulfil the **functions** of **subsystems** that have been eliminated" (1972, p.157 – retranslated from Spanish!).

This would be possible only if some **subsystems** were **redundant**.

J. NEEDHAM reproduces DRIESCH's diagram of the characteristics of an harmonious equipotential system (1968, p. 52). Some embryonic element X as a **part** of the embryo forms simultaneously part of different potential **subsystems** and "its **prospective value** is different in each case." DRIESCH spoke of a "prospective potency", in order to signify the collection of

possible fates of such a part: the actual fate (the prospective significance) is chosen from among the possible fates (the prospective potency) (p. 53)

The original embryo has thus the general character of a **hologram**. this is confirmed by the fact that, after dividing the embryo a typically whole gastrula appears "differing from a normal one only by its smaller **size**" (p. 52).

This shows that the original embryo (and possibly any system in its initial stage- see CSANYI **zero-system**) has a specific potential for global differentiated **organization**.

NEEDHAM adds the following suggestive comment: "...one of the most fundamental **process** in **development** consists in the closing of doors, i.e., in determination, in the progressive restriction of the possible fates" (p. 55) and "Prospective potency (becomes) ruthlessly curtailed to prospective significance" (p. 56)

The foregoing shows the very general meaning of equipotentiality

→ **Constraint; Differentiation; Embryogenesis; Gradient; Holon; Positional value; Structure (Dissipative)**

1162

ERGODIC PROBLEM ^{1) - 2)}

The difficulty to determine the nature of the **behavior** of a system depending of various ill-defined **variables**.

According to J.S. GRIFFITH this problem appears: "... when the **long-term time** average of a property of a dynamical system is equal to the average of that property over the **phase space** of the system" (1965, p.92).

While this is a problem that originates in classical mechanics, it becomes more and more important for **complex systems**, particularly those not very strongly integrated, as **populations** for instance. It is now clear that it has a close relation to **networks behavior** and to **deterministic chaos**, in accordance with H. POINCARÉ first inklings, when he considered the **3-bodies problem**.

A basic character of **networks** is the presence of various simultaneous **initially unconnected conditions**, i.e. the basis for **chaotic behavior**.

All **determinisms** do not disappear in **chaos** and return of former **states** is always possible. However the "**long-term**" condition is of basic importance, because the reappearance of some specific **state** may need a very long **span** of **time** when the original conditions are numerous and out of **phase** on a considerable **scale**. Consequently, it may be very difficult to establish the ergodic character of a system's **behavior**.

1163

ERGODIC RELATION ²⁾

The character of the **behavior** of a system whose average transit between successive **states** in **time** statistically equates the probabilities of the different possible **states**.

L. BRILLOUIN enounced the ergodic hypothesis, already introduced by BOLTZMANN, in the following way: "The average of some relation, measured through a **period of time**, must be equal to the average of the same relation, taken on the surface of constant **energy**".

According to BRILLOUIN, the idea was "to follow some determined **trajectory** and to show that it progressively covers the surface of constant **energy**, in the way that a wire covers a coil or a thread the surface of a ball".

However there are some difficulties, thus stated by BRILLOUIN: "Some peculiar **trajectories** are **periodic**, close on themselves and do not cover the surface in a uniform way. Others reach **bifurcation** points where different probabilities must be introduced for different branches" (1959, p.189).

The mentally uncomfortable mix of **determinism** and **randomness** appears clearly in the former comment. The same problem is reflected in other comments by W.R. ASHBY about "**equilibrium** in a **MARKOV chain**" (1956, nr.9/6) where it can be seen that, within a **population**, the **distribution** of differently characterized sub-groups tends at any moment to be equal to the mean **behavior** through **time** of these groups. Such systems are neither perfectly **deterministic**, nor perfectly **random**: individual **randomness** is limited by the characteristics of the individuals, which define the **limits** of their **autonomous** and collective **randomness** in relation to the specific environmental conditions and to the global mix of the different types of **autonomous** individuals.

These intricate **situations** seems to be related to:

1. the general theory of **deterministic chaos**: the ergodic relation holds only so far as the system maintains itself within the **limits** of its **attractor**.
2. the **concept** of **organizational closure** as it might be applied to **populations** (in a very general sense).
3. and possibly the concept of **self-criticality** in **composite systems**.

These systems seem to possess a kind of collective, but **blurred memory** of their **initial conditions**, which become mixed up with **time**, but are never totally erased.

The **POINCARÉ section** seems to have been the first specific **ergodic relation**, characteristic of nearly **chaotic systems**, being also useful for the study of **periodic trajectories**.

1164

ERGODIC SET²⁾

The set of all the **states** which can be visited by an **ergodic system** (after G. PASK – 1961, p.123).

The ergodic set is called regular if "...each of the possible **transitions** can take place at any instant" (Ibid). This is not always the case, as some systems can be ergodic and, at the same time, subtly **cyclic** in the long term (Ibid).

1165

ERGODICITY^{1) – 2)}

Character of a system in which the average **values** of the **variables** evolve through **time** within the **set** of their statistically **invariant values** over all possible **configurations**.

Ergodicity reflects the existence of subagent global and invariant conditions which determine the **behavior** of the **variables** only in a statistical way, but within **limits**.

Y. SINAI considers as the basic problem of ergodic theory: "the analysis of the causes generating the appearance of statistical laws in **dynamic systems**" (1992, p.69).

The **behavior** of an **ergodic system** evolves within a **phases space** that becomes divided into subspaces. As expressed by S. DINER: "Ergodic theory is basically a theory of the **sets of trajectories**" (1992, p.348).

As shown by BIRKHOFF (1931), the most significant characteristic of ergodicity is that the average **behavior** of the system over a sufficient lapse of **time** tends to be equal to the average **configurations** in **space**. This average on **space** is independent of the **trajectory** considered and the average in **time** is independent of the initial point. The **behavior** is thus not truly **random** and could be called **para-random**.

In consequence, the **behavior** of **chaotic systems**, with a number of **initial conditions**, tends to be ergodic.

→ **Ergodic relation**, (according to ASHBY).

1166

ERROR²⁾

In a **regulator**, the difference between the real and the desired (**reference**) **input**.

The error is measured in an iterative way by the **comparator** and its **value** sent to the **controller** in order to produce the needed correction.

As the correcting **process** suffers necessarily a certain **time lag**, the error may never disappears totally and the regulating **process** turns iterative and continuously produces **oscillations** within some more or less wide **limits of amplitude**.

If the error changes from positive to negative – or the reverse – during the corrective **process**, the correction may well amplify the error instead of damping it.

1167

ERROR ACTIVATION²⁾

The **activation** of a corrective **response** by the **feedback unto the process** of the **difference** between some present **state** and some previously registered desired **state**.

This is a property of **regulators** and a basic feature of any **control system** or **subsystem**.

1168

ERROR CONTROL²⁾

The compensation of any **process deviation** that could lead the system to an **instability threshold**.

The control of errors by **feedbacks** was at the origin of cybernetics. It aims at **dynamic stability** in **processes** and systems by maintaining their **fluctuations** within predefined **limits**. It was discovered and practised empirically various centuries before the theoretical work of N. WIENER.

Error control is obtained through the iterative **measurement** of errors, used by the control device as **data** to determine by comparison with the established **stabilization standard** the needed counteractive **action**. See: "**control by error**".

1169

ERROR CORRECTING CODE²⁾

In a **communication device** "An **encoding code** which corrects **messages** that contain **transmission errors** of up to a certain number per **message**".

K. KRIPPENDORFF, author of the definition, states that "A code is error correcting only if the **HAMMING distance** between the **messages** sent, exceeds twice the number of transmission errors per **message**" (1986, p.28).

1170

ERROR DETECTING CODE²⁾

In a **communication device**: "An **encoding code** which correctly identifies **messages** that contain **transmission errors** of up to a certain number per **message**, without the ability to correct them."

K. KRIPPENDORFF, also author of the definition, again adds that: "A code is error detecting only if the **HAMMING distance** between the **messages** sent, exceeds the number of **transmission errors per message**" (1986, p.28).

See "**HAMMING distance**".

1171

ERROR SIGNAL²⁾

The difference between the reference **value** of some controlled **function** and the **value** observed by the **control system's comparator**.

The **perception** of an error signal triggers a specific correction, but only through a well constructed **regulator**.

Alternatively W.T. POWERS describes it as a signal that "produces an **action** that tends to correct the error" (from POWERS homepage).

"If the **control system** is very sensitive to small errors, it won't take much of an error to produce an **output** large enough to prevent any further **drift**..." (Ibid)

In fact, the basic point is about the degree of **complexity** of the **environment**, as related to the system.

In a thermostat, the error signal is obtained from a very simple device measuring a unique well defined **variable**, easy to install and to organize for perceiving specific **inputs**.

In a human driver - the example given by POWERS - the error signal becomes much more complex in itself and supposes an also highly complex integrated regulator: the **nervous system**, including the whole of the **neural network** in the **brain**.

1172

ERROR-FREE REPRODUCTION^{1) – 2)}

Error-free reproduction is possibly the main problem for **complex systems**, in which not only **structures** and **functions** must be maintained, but altogether, in H. ODUM's words: "There is the additional work of maintaining an error-free **plan** or generating an improved plan by combining extra **reproduction-generating choice** and **selection**..." (1971, p.142).

Error-free **reproduction** is not **free**. It demands an extra cost in **energy**.

1173

ET CETERIS PARIBUS^{1) – 3)}

This well known latin quotation whose **meaning** is "other things being equal" is in fact the banner concept of **linear causality**.

It is of course a pure **abstraction**. **Context-free situations** do not exist. There is not one single natural sequence of **events** in which all "other things are equal". It is also unsound to postulate the **identity** of two merely **similar situations**. They only should be **compared**, which of course leads to discover not only their **similarities**, but also their **differences**.

"This *ceteris paribus* limitation account for the inability of otherwise able analysts to develop meaningful **scenarios** for the future. It is a source of serious problems in **risk management**" (I.I. MITROFF and H.A. LINSTONE, 1993, p.126).

Nevertheless, the **linear causality** concept remains very useful to obtain functional laws and principles that can be used *within limits of validity that must be established*.

Models thus constructed on a **linear** causal basis should be considered either as approximations whose use must be qualified, or as formalisms of some specific type.

1174

ETHICS AND MORALITY ¹⁽⁴⁾

Heinz von FÖRSTER wrote in a letter to Monika BRÖCKER "As you know, it is for me of decided importance to separate ethics and morality once and for all. Morality is characterized, as you will remember, by two points. The first being that every statement, every **rule**, every law of morality is directed to the other. The decalog is a good example: "thou shall not kill", "thou shall not covet thy neighbor's wife", etc. etc.

The second point being that the authorities, that postulate these laws, are themselves not subject to these laws" (H. von Förster & M. Bröcker, p. xix, 2002) (In the German original)

About the first point, von Förster observes that it reflects the **self-organizing** nature in any society. And as to the second point, enforced obedience is the **mechanism** that forever in the past guaranteed the **maintenance** of self-organizing society.

However when it comes to ethics, von Förster is generally quite elusive: "Ethics is implicit in what I say". Which apparently means ethical **responsibility** is not merely to comply with rules by obedience, but to decide for oneself what should be said or done, i.e. to take the full personal responsibility for one's **behavior** and **actions**. von Förster concludes: "I just remembered that perhaps the best analogy to the problem of speaking about ethics appears in Chinese philosophy, where they have the difficulty of speaking about the Tao" (Ibid) and "Ethics do not contain guidelines" (p. 14)

It could possibly be said that morality is compulsive within a prescriptive view of an **auto-poietic** society, while ethics delegates **decisions** to individuals endowed with a deeper **understanding** of their relations within society whose global survival is the only guarantee for everybody's personal survival.

And, after quite - long soul- searching, Heinz von Förster concludes "Ethics is the **behavior** with which I make myself responsible for my **actions**" (p. 49, 2002)

The known psychiatrist and logotherapist Victor FRANKL considers that "moral" can survive only if it becomes rooted in existential and **phenomenological** experience. This is again transfers us from a **top-down** autocratic concept of morality (implying mere passive compli-

ance) to a **bottom-up** constructive ethics based on individual and personal evaluations of the effective or potential consequences of one's own **behavior**.

Even so, it is still very probable that such evaluations will be tainted by psychological **constraints** of **cultural** origin and even group membership (the much praised "esprit de corps" or "spirit of the hive")

The whole matter remains, even in systemic terms, an elusive conundrum.

→ **Autopoiesis; Commons; Conversation; Decision making; Free will**

1175

ETHICS as related to Mindscales ⁴⁾

Ethics has been defined as the "science of the **oughts**" (A. BAHM, 1992)

But to make it a "science", we would need precise criteria about the way these "oughts"-should be defined, which is of course quite difficult.

According to M. MARUYAMA (1994, p. 125-6) the ethical attitudes are quite diverse and become established on the basis of the very different mindscapes dominant in distinct **cultures**.

He thus distinguishes the following basic ethic pronouncements by the representatives of the four basic psychomental types he describes:

- the H type (homogeneous, hierarchical) considers that "the stronger should dominate the weaker" (thus "order reigns")
- the I type (heterogenist, randomizing) thinks that "everybody should be self-sufficient" (- being poor is a person's own fault")
- the S type (heterogenist, cooperative) believes the "different individuals should help one another" (Harmony should be sought and maintained)
- the G type (heterogenist, co-creative) vows that "New diversity should be generated" (Change is good and should be sought for")

Of course these divergent views are the main cause of the eternal and labyrinthic search for an ethics acceptable by everybody.

Maruyama applies the same views to aesthetics (Ibid, p. 126-7)

1176

ETHICS (Normative) ⁴⁾

G. MINATI considers normative ethics as "a self-designed social **software**", or "social self-designed **space** of **rules** in which social systems behave" (2002 a)

In such a **process** **agents** and **collective beings** behave giving rise to new processes of **emergence** affecting both natural **environment** and current social ones".

And "This social space of rules strongly influences **behaviors** of collective beings, i.e. available, used **cognitive models**".

These views, while seemingly meaningful, would need some clarifications:

- could "Collective Beings" be assimilated for example to **rule-bound human systems**?
- How exactly do agents insert themselves in "Collective beings"?
- How does this **metalevel** ruled space arise out of interrelated agents actions? Could for example the **network model** be useful and how?
- What could be the **role** of "cognitive models" in "**cultures**"? Or are cultures implicit "cognitive models"?

As to "ethics", if "normative", it is very different to the personalistic ethics of von Förster, for example.

→ **Autopoiesis; Closure; Ethics and Morality; Morality; Semantics (General)**

1177

ETHICS OF TECHNOLOGY CREATION ¹⁽⁴⁾

This very important issue does not yet seem to be considered with a sufficiently serious attention.

To all of the technological developments of the 20th century, the following words of A. BEDAU can be applied: "The development of a powerful new technology usually has ethical consequences. Atomic fission and fusion provide examples from recent history, and today genetic engineering threatens to teach us this lesson again. The havoc wreaked by computer "viruses" and "worms" provide ample evidence of the destructive power of artificial life technologies; precautions must be taken against their accidental misuse and intentional abuse" (1996)

Bedau could have cited numerous other examples: military uses of aircrafts, uncontrolled use of pesticides, imprudent use of antibiotics, etc.

In fact, the issue is very complex:

- 1) The discoverer generally feels that he is making a very positive contribution, specially if he/she is a scientist
- 2) He/she quickly loses control on the derived technologies
- 3) Psychological and sociological factors (greed, lust for power, and even pure irresponsibility) introduce undesirable and unethical deviations in the technological applications
- 4) When the "genie already escaped from the bottle" there is usually no way to put it back in it.

The subject should deserve a systemic **inquiry** into the deeper mechanisms of the whole **process** using for example **models** like **small-world** propagation, **bottom-up** and **top-down** processes, **competition**, **awareness**, **norms** and **values**.

The crucial question mark seems to be:

- Why is there such a difference between what ought to be and what happens in fact?

- What could be done about unexpected **side effects** and **delayed effects**?
 - How could personal **responsibility** be enhanced by social education, i.e. how could individuals be made fitter as members of their society?
 - What could be done to better **forecasts** about technological side effects?
 - What kinds of **regulations** and/or **controls** could societies establish to avoid negative effects of technologies?
- ...and how to avoid in turn, negative effects of these legal (or other) devices?

And last, but not least, how could ethical or unethical **behaviors** derived from technology be accurately assessed and valued, and by which social arbiters?

In short, this issue is overriding and a major systemic issue

1178

ETHICS (Systemic) ^{1) - 3) - 4)}

"Code of conduct and responsibility that **agents of change** ought to follow when designing systems" (J. van GIGCH, 1978, p.590).

van GIGCH states: "The ethics of systems is concerned with the **values** held by the planners and the designers of systems and the consonance of these **values** with those of the recipients. These issues also revolve around the problem of obtaining **consensus** for the implementation of systems acceptable to all" (p.75).

However, this is still the "ought of the ought". Besides, general acceptability is necessary, but *not sufficient*. While in systemic ethics, **values** are basic, so are however, *for all stakeholders*, sound **knowledge** and **understanding** of why the **situation** is as it is, and which are the real (i.e., factual, not merely based on idealism or **ideology**) possibilities to modify it, if needed. No sound systemic ethics is possible without well informed **understanding**. In this century, we constructed many hells paved with good intentions. In this sense, see for example J. WARFIELD on **Global Design** and **underconceptualization**.

van GIGCH himself takes good care to study what he calls the "ethics of spillover **effects**". He shows how advantages and disadvantages of any **change** should be pondered. He also defines a comparative ethics of **goals** and extends himself to the ethics of social responsibility and general conservation. He ends up with some reflections about the "realist versus the idealist" (p.145-68).

The crux of systemic ethics is that, notwithstanding some important contributions, their precise content has not yet been clearly expressed, nor unanimously accepted.

According to A. BAHM (1992), ethics is the "science of the ought". **Systemics** do indeed reveal some aspects of general **organization** (in **ecosystems**, in **sociosystems**, etc...) which formerly were widely ignored or undervalued.

In this perspective, some disorganizing **activities**, even when unwittingly pursued, may be judged unethical. We should become aware of our new **responsibility** to manage **organizations** and natural and artificial systems in non-destructive or damaging ways.

It becomes obvious that such **situations** cannot be correctly (i.e. ethically) managed without a good **understanding of complexity**. The systemic view thus amplifies our ethical commitment by introducing a critical new dimension to our worldview.

While until now ethics related only to **relationships** among humans, it becomes now urgent to extend it to a concern for life in general in an **ecological** perspective, would it even be merely to maintain the **survival** potential of mankind itself and of many human **groups** in particular.

J. van GIGCH formulated the basics of what he calls "Metaethics" (1990). He thus distinguishes three ethical **levels**:

1. The inferior **level**, i.e. the user's one, i. e. of individual **rights** and duties, regulated through legal **rules** and **norms**;
2. The normative **level**, established by theologians and social scientists, wherein **concepts** like "good", "bad", "correct", "incorrect", etc... are produced in relation to **behavior** standards;
3. The metalevel, where **epistemological** and logical aspects are considered and ethical judgements are evaluated as "true" or "false".

Even at that upper **level**, we still need **criteria**... and mankind accelerated **evolution** itself tend to extend these **criteria**. Metaethics should corresponds to **metasystems**.

Some very general tentative systemic ethical principles may be formulated in the following ways:

- What is good for the system should also be good for its **parts**.
 - No **part** has the right to inflict damage to the system to which it belongs.
 - What is good for the system should not be nocive or destructive for the **metasystem**, or **subsystems**.
 - What is good for the system should not be nocive or destructive for another system.
 - Act always so as to increase the number of **choices** (von FOERSTER).
- Systemic ethics should also explore the following ethical problems:
- What are the limits of the system's right to fight for its **survival**? Which **criteria** should be established and by whom?
 - Has the system the right to destroy one of its **parts**, if dangerous for its own **survival**? Which **criteria** should be established and by whom?

Systemic ethics is thus many-dimensional, including bio-ethics, ecological ethics, economical ethics, socio-ethics, etc., all of which becomes translated into the ethics of personal **behavior**, and also should become integrated

in the law system, both in law itself and in the judge's ethics, who, apart of a purely legal viewpoint, should take responsibility for the positive and/or negative consequences of his/her decisions (E. GRÜN, 1995, p.66).

Systemic ethics is becoming an urgent must in an ever more complex and integrated world and should be applied to ecological, economic, political, social and scientific research **situations**, if gigantic disasters are to be avoided.

With the progressive self-construction of a **man-planet system**, the relations between individual and **groups** ethics with a planetary eco-ethics start to loom larger and larger. The following comments by G. HARDIN help to make the point:

- "The disadvantages of each new intervention in the web of life increase with **population** size (1976, p. 65)
- "One of the principal aims of the **automation** is to purge **control** systems of ego (p.105)
- "Beyond the limits of his confining skin, no man can own *anything*. **Property**" refers not to things owned by the rights granted by society; they must periodically be re-examined in the light of social justice (p. 127)
- "We are not free to violate the laws of nature. We become free when we recognize their necessity"(p. 132)

This last comment becomes crystal clear in systemic terms with the following quote:

- "The morality of an act is a function of the state of the system at the time the act is performed"(p. 134)

Of course, there are at least two fundamental difficulties arising from HARDIN's "ecological ethics":

1. A satisfactory **knowledge** and **understanding** of the "state of the system"(at village, or at planetary level) is quite difficult to obtain individually, still more difficult to reach at the **community level**...and still more so at the global mankind level
2. Naked greed is in most cases a much more powerful motive than yearning for common good. An it leads ultimately to global mankind **parasitism** on its cosmic home

Both factors could easily become the ingredients for global disaster

1179

ETHNOCENTRISM ^{1) - 4)}

The prevalence of a type of **mindscapes** and of its bearers in an **organization** or in a **culture**.

It is quite normal, probably inevitable, and possibly necessary that a system of **values** and **norms**, reflected in **mindscapes**, be predominant in any organized **human system**. It can be equated with a specific **order parameter**, in accordance with H. HAKEN **slaving principle**.

The problem is that it leads frequently, through ignorance or scorn of other **values** or **norms**, to serious mistakes, abuse, oppression and even cruelty.

Ethnocentrism as a systemic **problem** is widely explored by M. MARUYAMA (1994, p.42-5).

→ **Technocentrism**

1180

ETHOLOGY¹⁾

The science of animal **behavior**.

Ethology brought very significant contributions to the general store of systemic concepts and **models**, the most important listed hereafter:

- A better **understanding**, by comparison, of human **perception**, by demonstrating that the **observation** windows of different animals are far from being similar to those of men. **Perception** is conditioned by sensory sensibility (for example to infrared or ultra-violet radiation, or capacity to perceive or not some sounds, etc.). It also depend on size, stature and position, which is important when comparing children and adults **perceptions**.
- A keener understanding of **living systems'** individual as well as collective **interrelations** with their respective correlated **environment**. See f. ex. "**stigmergy**".
- More recently, by the study of social insects, through the **understanding** of the nature, workings and implications of **communication** for **sociality** in living beings and, possibly in the future, of societies of artificial **organisms**.

The most important school of ethology has been the German one (Bibliography: von UEXKÜLL, KRISZAT, LORENZ, EIBL-EIBESFELDT). Insect ethology is recently more of an Anglo-saxon concern (T. SEELEY, J. and C. GOULD, E.O. WILSON, W.C. ALLEE, D. GORDON). African primates have been studied by J. GOODALL, D. FOSSEY, F DE WAAL and others.

According to REVENTLOW (1973)- as quoted by S. BRIER (1992, p. 75): "As ethology demands that animal and human **behavior** be examined in relation to their **biotopes** and at all times strives to understand psychological **phenomena** on the basis of the **relationships** between **stimuli**, **motivation** and behavior, ethology becomes one of the broadest psychological theories in existence-and certainly the most ecologically oriented

"In lieu of "theories", it would possibly be better to speak about " observation tools". Indeed, Brier makes the point quite clearly in his paper.

1181

EUSTRESS⁵⁾

The excitement that accompanies an appropriate degree of personal challenge (R. NUMMELA CAINE & G. CAINE, 1994, p. 72)

H. SELYE himself, who introduced the notion of **stress**, duly expressed that **stress** can be a positive as well as a negative **reaction**. He even invited his readers to enjoy the stress of life!

1182

EVALUATION in systemic terms^{1) - 3)}

The **process** of verifying whether a system performs as expected.

The crux of the matter is to define what *should be* expected of the system.

In many cases what the **evaluator** expects is not what the system is able to offer, because she/he does not really understand its workings and its production conditions.

The evaluator should thus begin by questioning her/his proper **knowledge** of the system and **validity criteria** of expectations.

1183

EVALUATION LOOP (Self-)²⁾

This **brain** feature is proposed by the French neurologist J.P. CHANGEUX, according to whom such loops: "cut the reward **signal** coming from the outside world and allow a "tacit" testing of motor intentions, on the base of the memorized traits of a former experience" (1992, p.712).

This seems quite close to H. MATURANA's concept of **self-reference** and **organizational closure**.

It is even probably a quite more general property of **networks** of any kind.

1184

EVALUATOR²⁾⁴⁾

A device within an **adaptive system** that "calculates an estimate of the "distance" of any given situation from the **goal**"(J. HOLLAND, 1992, p.48)

The evaluator needs to receive **information** from **detectors** about the results of the most recent **actions**.

HOLLAND observes: "There is however a caveat. If the set of detectors is inadequate, for whatever reason, the improvement of the evaluator will be blocked. This raises the broad issue of **pattern recognition**, for the **set** of detectors is, of course, meant to enable the (genetic adaptive) plan to recognize critical features for **goal-attainment**" (Ibid).

HOLLAND also offers adequacy criteria for detectors: "The estimates are supposed to take the costs of the **transformations**, etc., into account; that is, the "distances" are usually weighted **path** lengths, where the paths in-

involved are (conjectured) sequences of transformations leading from given **situations** to the goal. The intent is to use these estimates to determine which transformations should be carried out next. An evaluation is made of each of the situations which could be produced from the current one by the application of allowed (simple sequences of) transformations, and then that (sequence of) transformation(s) is executed, which leads to the new situation estimated to be "nearest" the goal." (Ibid)

Evaluators are an essential part of any **adaptive system**, from biology to business and artificial life devices.

1185

EVENNESS²⁾

A measure of **diversity** in some defined **space**

C. WILLS writes: "If a minority of species in a quadrat are common and the rest are rare, it is considered to have low evenness. But if, in another quadrat with the same number of species, all the species are equally common, then the quadrat's evenness is high" (1996, p.42)

1186

EVENT¹⁾

1. "A point in **space-time**, precisely localized by its three spatial coordinates and its time coordinate" (J.P. LUMINET, 1987).

2. "A **change** in one or more structured properties of either an **object**, a system, an **environment** or a **relationship** between them over a **time period** of specified duration" (R.L. ACKOFF & F.E. EMERY, 1972, p.25).

LUMINET comments to his most general definition that "the separation between two events remains absolute, whatever reference system is used".

In accordance with ACKOFF and EMERY definition, an event must frequently be an unforeseen happening.

From a very basic viewpoint, G.L. FARRE expresses that "events are the traces left by these **transformations**"(i.e. of **energy**)

As energy acts at different **levels** in nature, we have gravitational, chemical, electro-mechanical, biological, or microphysical and **quantum events**.(1998b, p. 262)

An **event** does not always fit into the sequence of **situations** which seemed possible within the formerly forecasted or awaited ones. As stated by J.van GIGCH, unique events, far away from standard statistical **deviations**, can be enormously important (1978, p.212).

In the study of a **complex system**, it obliges us to question our **knowledge**, or at least the **model** that we had formerly built.(in an explicit or implicit way).

Such failures in **forecasting** are generally results of:

- the ignorance or disregard of some basic aspect of the system or its **interactions** with its **environment**;
- the ignorance or misappreciation of the irreducibility of **long term transformations** to **medium or short term** ones.

3. For the French biologist J.P. CHANGEUX an event is "Any modification in the **environment** or of the system itself that may modify its **dynamic stability (Homeostasis)**" (1972, p.37).

CHANGEUX's definition refers only to **living systems**. It seems however that it can be applied to **social systems** and, possibly in the future to artificial **distributed intelligent systems**, if it becomes possible to endow them with the ability to modify their collective **behavior** by **learning** through **behavior rules**, without any rigidly imposed **algorithmic control**. (see "**Artificial Life**").

Following this definition, the event may oblige the system to *create* a new **response** (i.e. to learn) and not merely to cross-over from one **state** to any other, previously visited or known.

From a **constructivist** and physio-psychological viewpoint, in R. FISCHER words: "... **environmental events** are specified as internal **states** that are - in mammalian **brains** - the neural system's own **symbols**, as these **states** stand in regular relation to events in the world and signify potentials for **action**" (1992, p.219).

An event can be destructive if the system does not discover some efficient **response** to it. It may also lead merely to a broadening of the system's **states repertory**. In this case, the system maintains its **organizational closure**.

As a third possibility, the system could be so radically modified by the event that its basic **identity** becomes altered. This could lead to **emergence** (if the event is a massive increase of **energy** supply), or to **evolution**, if the system's basic **organization** is altered by a nonlethal mutation.

1187

EVENT AND ELEMENT ^{1) - 3)}

E. MORIN writes: "a) The notion of element relates to a spatial **ontology**. The notion of event relates to a temporal **ontology**. Now, any element may be considered as an event if viewed within **temporal irreversibility**, as a manifestation or actualization, or in **function** of its singularity. **Time** impose an "eventuality" coefficient to anything".

b) In other words, ambivalence reigns always between event and element "while there is no "pure" element (i.e. any element is **time-binded**), there is also no "pure" event (it always relates to a system) and the notion of event is relative".

c) Still in other words, "... the accidental, aleatory, unlikely, singular, concrete, historical nature of any event depends from the system under which it is viewed. A same **phenomenon**

is event within some system and element within another. Example: traffic deaths during week-ends are predictable and probable elements within a demographic-statistical system, which obeys strict laws. But each one of these deaths is, for the members of the family, an unexpected accident, a misfortune, a concrete catastrophe" (1972, p. 17).

1188

EVENT-BASED EPISTEMOLOGY ³⁾

H.von FOERSTER observes: "**Objects** and events are not primitive experiences. "**Objects**" and "**Events**" are **representations** of **relations**" (1992, p.265).

This has also been shown by A. KORZYBSKI with his "**structural differential**" (1933, 1950, p.386-411): we all must start from "something out there", but we only can make sense of it in *our own* perceptive and conceptual terms. Thus any "event" is already no more than a more or less accurate and efficient *fabrication*.

This appears clearly when, in a different sense, M. Mc WHINNEY and D. BUSHNELL emphasize that: "Classificatory **epistemologies** are derived from **observation** of systems in **equilibrium**, thus they organize **knowledge** in accord with normal **distributions** of **matter** and **energy**, ones that present the "typical" **distribution** of explained **phenomena**. Such is the foundation of contemporary sciences, social as well as natural" (1987, p.291).

In other words, we mostly live on an epistemology of **stability**, or at most **dynamic stability**. But this blocks effectively our **understanding** of any kind of system that does not conform with this **model**.

Thus the cited authors propose: "Systems practice in an era of turbulent **change** calls for an "event-based" approach to **understanding**. Such an approach to establishing **meaning** recognizes that **emergent systems** have unique properties, not predictable from the **behavior** of **component subsystems**. Thus extent **classification rules** inappropriately filter out new or highly unusual **phenomena**. An event-based **epistemology** provides a better basis for **understanding behavior** in **dissipative (self-organizing)** systems which operate far from the presumed **equilibrium** conditions. This is true of all **dissipative systems**, but we see the effects especially in those that are directed by sentient and **purposive** beings" (p.291).

The lack of such an epistemology hinders gravely our **understanding** of the present massive **transformation** of mankind, which is probably on its way to global **integration** at planetary **level**.

1189

EVENTS as percepts ³⁾

An event is basically the **perception** of a **change**, or a **distinction** between a former and a later **state**. It is not clear if we perceive events through **time flow** or **time flow** through the succession of events: In J.J. GIBSON's words: "Events are perceived, but **time** is not" (1986, p.100).

Another intriguing aspect is that events are perceived in function of a more or less stable **background**.

Furthermore, the events that are perceived depend on the **time-scale** of each perceiving system. Events for a caterpillar or a mosquito are those which occur within the reference **time frame** of a season. Human beings are able to perceive some events on a yearly **scale**, and even with more abstract insight, on a geological **scale**.

Any event is inscribed in a specific **space-time frame**, related to a specific class of **observers**.

1190

EVENTS (Structural class of) ^{1) - 3)}

"A **set** of events that consist of similar **change** of the same **structural** properties" (R.L. ACKOFF & F. E. EMERY, 1972, p.25).

This is a very general concept, allowing for the construction of **transdisciplinary models**. A good example of such a **structural class** are R. THOM and E. ZEEMAN "**catastrophes**". **Bifurcations**, **threshold crossings** or **dissipative structuration processes** are also structural **classes** of events.

According to ACKOFF & EMERY : "...the **cause-effect** and producer-product relations apply to events and to the concepts derived from them".(Ibid).

1191

EVOLUTION ^{1) - 3)}

The accumulative **transformation** of systems undergoing **irreversible changes**.

Evolution is a **global process**: Any **change** in some **part** of a system inevitably evokes correlated **changes** in other **parts** until a new type of **dynamic stability** is attained... if ever!

Evolution seems to correspond to a very general **trend** in nature tending to shape **open algorithms**: biological, but also behavioral and even technical ones.

By *open* it is meant: having the potential to produce **emergent** and radiating **levels of organization**, nevertheless necessarily based on the formerly established ones.

It should never be forgotten that "evolution" is a concept. W. REEVES writes in this sense: "Evolution is a general way of conceptualizing the **self-organizing selection process** of the universe displayed in the increasing **complexity** which occurs as a result of the dynamic bal-

ancing effort of **entropy** and **negentropy** through the **process** of **fluctuation**, **amplification** and subsequent **bifurcation** allowing successful **phase transition** and **emergence**" (1992, p.1102).

Many definitions more or less at variance with the proposed one are used by biologists, paleontologists, anthropologists and sociologists.

In any case, it seems basic to understand that *individuals* do not evolve: they merely adapt in accordance with their genetic inheritance, characterized by their **organizational closure** (in very unfrequent cases, affected at its very beginning by some mutation, which introduces a measure of **randomness** in the **process**). On the contrary, **populations**, species or societies evolve, as connected **wholes**, but through their individual members, who act as possible **transmitters** of **changes**, eventually inhibited, limited or favored by circumstantial **environmental** conditions. This again is in part a stochastic **process**.

H.G. BURGER expresses it in this way: "... all types of evolution... consist of a rivalrous **polymorphism** that awaits **environmental change**" (1967, p.209).

A. LOTKA's discussion, in 1924, maintains still its validity, specially in systemic terms. He stated in his chapter on this topic: "Evolution is not a mere changeable sequence... (this) is insufficient to define the *direction* of evolution.

"... the thing to mark is that what has imparted to the **process** its directed character is frictional resistance, **dissipative** forces, typical **irreversible effects**, to speak the **language** of the physicist...

"... such internal **changes** in a material system... lag behind the determining external **changes**" (1924, p.22- 26).

LOTKA bases thus his views of evolution on his **understanding** of **irreversibility** and of the ambiguous character of the concept of **reversibility**: to obtain **reversibility** (this is, a return to a *previous* condition), a **process** of (*timely*) **change** of the condition of the **function** or system is necessary. Thus, while some **states** of a system, or values of a **function** may be *repetitious*, is it confusing to qualify them as "reversible".

LOTKA concludes: "The law of evolution is the law of irreversible **transformations**; that is, the *direction* of evolution is the direction of **irreversible transformations**. And this direction the physicist can define or describe in exact terms. For an *isolated* system, it is the direction of increasing **entropy**. The law of evolution is, in this sense, the **second law of thermodynamics**" (p.26).

He observes that this is in accordance with CLAUSIUS since the Greek word from which he derived '**entropy**' precisely means 'evolution'.

Let us however observe that he also writes: "... we should constantly take in view the evolution, as a **whole**, of the system (**organism plus environment**)" (p.16).

Still more generally, he parallels evolution with a "**law of maximum energy flux**", meaning that still unused **energy** is the power house of evolution and implying that it tends to transform free **energy** into higher **levels** of **organization**.

As PRIGOGINE demonstrated many years later, there is no contradiction between the *general* increase of **entropy** and the *local* increase of **complexity** in systems, by **structuration** through **energy dissipation**. PRIGOGINE even sees this feature as the basic operative way in evolution: **instability** induced through growing **fluctuations** → increasing **dissipation** of **energy** → **threshold** → **bifurcation** → **emergence** of new and more complex **forms**.

In E. LASZLO's words: "Evolution... exploits **energy-flows** which possess inherent **stability** in certain highly specific **configurations**. It takes place in **open systems** with **inputs** and **outputs**, whereas the **laws of thermodynamics** apply to **closed systems**" (1974, p.206).

LASZLO synthesizes his views as follows: "... separately investigated branches of evolutionary disciplines... disclose a dynamic that is **isomorphic** in its essentials with the **nonlinear dynamics** of **bifurcations** in the **complex system** investigated in **nonequilibrium thermodynamics** and dynamical systems theory" (1993, p.113).

Of course, the **laws of thermodynamics** apply also to **open systems**, but in a different form. See: "**Entropy production in a system**".

The concept of evolution through use of intrinsically well configured **energy flows** (in *fields*?) is quite close to LAVILLE's concept of form shaping through **energy vortexes**, or D. Mc NEIL's **toroids**.

Evolution seems to be related to:

- **Adaptability** in **self-organizing** systems by reaction to environmental **noise** through **random** mutations some of which prove to possess adaptive value.
- **Interaction** among such transformed **self-organizing** systems, which then react reciprocally within the **constraints** of their common **environment** and eventually (but not necessarily) diffuse their new characteristics. H. LABORIT writes: "...it is difficult to conceive that evolution could occur only by **random** reorganization of the **interrelations** within a **set**, but more easily by **addition** of new **elements** to this **set**, by way of its intersection with another **set**" (1972, p.114).

P. WINIWARTER and C. CEMPEL thus summed up the general characteristics of **macro-level** evolution, as applicable to technology:

"1) A **global optimization** of **energy flows** (load **optimization**) for a **set** of "running" or "living" units;

"2) **Design** or **code modification** for the next generation of units (**adaptation**);

"3) Re-design, complete recoding or **code-creation** for an entire new technology (evolution)" (1992, p.32).

Still another interesting insight on evolution is D. LEPINARD's: "The evolution of the **behavior** of **cells** and animals through **time** can be understood as a progressive rolling up on the causal chains. Living beings tend more and more to stand back on vital acts, like eating or mobilizing **energy**" (1993, p.25).

In other words, **processes**, **perception** and **memory**, and in man's case, increasing **understanding** of the past allows for a growing internalization and **control** of vital **processes**, which could define the "arrow" of evolution.

However, evolution is also an accumulative **process**: once a really basic evolutive groove has been traced, it becomes fixed and is used as a baseline for further **development**.

Finally, quoting P.M. ALLEN, K.DE GREENE makes the following very basic observation: "Newtonian mechanistic systems can only function; they cannot evolve... The Newtonian **machine** cannot restructure itself or insert new **components**. It appears the **cybernetic/servo-mechanism** systems are just such Newtonian **machines** that can only function and that cannot generate the **emergence** of qualitatively new properties" (1994, p.7).

This comment can be extended to **Hamiltonian mechanics**. It explains why the **mechanistic-reductionist paradigm** is in need for the complementary systemic one.

1192

EVOLUTION (Co-) ^{1) - 4)}

Changes in a system and/or its environmental **co-systems**, as a result of reciprocal **action**, producing an evolutive **feedback process**.

According to R.N. ADAMS: "Co-evolution emerges when two or more **sets** of **energy** forms interact so that each becomes dependent for **survival** and evolution on the other. Co-evolution effectively blends the **process** of competitive Darwinian **selection** with the **environmental selection** of WALLACE" (1988, p.130). He adds: "The significance of co-evolution as a **process**, however, is that the **trigger - flow interactions** specifically create an *interdependent reproduction* among the participating **dissipative structures**. It interlocks a series of separately reproductive systems into a single interactive reproductive system" (p.133).

Co-evolution supposes permanent **interactions** between **flow lines** registering and transmitting **information**.

K.DE GREENE states: "Over **time** systems and **environments** co-evolve,... system's **changes** impact the external **environment**, and **changes** in this **environment** impact the

system. For organic **evolution** as a whole, **populations**, species, genera and families maintain **congruence** or **fit** with their **environment** over considerable **periods**. **Regulation** and **control** stem from the system-**environment relationship**" (1988, p.251).

DE GREENE proceeds by explaining how, in human systems, the co-evolution **interrelation** between system and **environment** is modified by **management**. In fact, as observed by H.J. and I. JERISON: "The **organism**, by its **actions** and preferences, partly selects the **selection** pressure which will act upon it and its descendants" (1980). This seems to have been true at least since the creation of an oxygen atmosphere by old and simple living beings.

Man however, having a more or less developed **understanding** of the **relationship** between his systems and their **environment**, tries (and is more and more able to do so) to modify it voluntarily, and even sometimes willfully. Moreover he does it mostly to obtain **short term** results in a supposedly **positive sum game**, ignoring **long term** results which may lead to "unchecked decay", in J. WARFIELD's words (1987, p.230).

Considering that, in E. JANTSCH words: "Coevolution is the generating principle of macrosystems, at least in the **domain** of life, but thereby a "vertical" dimension of coevolution is also implied by the coevolution of the macrocosmos and the microcosmos, the mutual enhancement in the evolution of **macrostructure** and **microstructure**" (1982, p.347). A better **understanding** of co-evolution, specially between man (the planetary super-predator) and the **biosphere**, is thus very important in order to avoid mega-disasters in the future of mankind. See for example the case of the Aral Sea, considered in systemic terms (CH. FRANÇOIS, 1989, p.1101-11).

St. KAUFFMAN observes that "... coevolutionary **changes** tend to occur in bursts followed by **periods** of quiescence" (1993, p.269). This rejoins S.J. GOULD and N. EL-DREDGE theory about intermittent and punctuated evolution (1993).

Co-evolution is now actively researched, using adaptive **automata**. One example is the **modelling** of the predator-prey evolving **interactions** leading to **adaptive transformations** in the **behavior** and the internal **controls** themselves of the automata. This research takes place at the Ecole Polytechnique Fédérale de Lausanne (Switzerland) (D. FLOREANO, 2002, p.24-28)

An important aspect of co-evolution is that it also implies co-extinction. This **phenomenon** is generally overlooked. It is however becoming now very frequent. For instance, the **destruction** of enormous tracts of tropical forests

leads, as a corollary, to the destruction of the **habitat** of a great number of vegetal and animal species. Many of them are condemned to extinction as a result.

→ **Evolutionary robotics; Red Queen evolutive parable; Selection in populations (Combinatory); Selection principle (Loop)**

1193

EVOLUTION (Energy cost of) ¹⁾

H. ODUM states: "In evolution, not only are the **structures** and **patterns** of the systems maintained against the disordering influences through duplication, **selection** and loopback currency, but, by definition of the term, novel **changes** are made. The power cost of the **change** is the power cost of making even more **choices** and **selections** than are required to hold the order stable" (1971, p.151).

This implies that any important evolution step supposes the existence of still unused **energy**, which allows for the shaping of some new type of system able to take advantage of it.

An extraordinary example is the explosive evolutive **structuration** of human societies since the discovery of new ways to use coal, oil and gas as sources of **energy**.

1194

EVOLUTION (Energy flow and) ¹⁾

A. LOTKA formulated an hypothesis according to which the essential logic of evolution corresponds to the maximal use of the available free energy.

He surmises that the planet as a whole is an energy **dissipative system**, under the guise of what he calls the "**world engine**". This latter would be a global system endowed with multiple **correlations**, being an integrated **set** of numerous coupled **energy transformers** (green plants, plankton, herbivores, carnivores) able to use maximally the global energy flow.

According to LOTKA, the basic tendency of evolution is to improve this **transformation** line by eliminating the less efficient species and favor the most efficient ones. He made (in 1924) this suggestive prediction, placing man as the most powerful **energy transformer**: "...the problem of economy in husbanding **resources** will not rise to its full importance until the available **resources** are more completely tapped than they are today. Every indication is that man will learn to utilize some of the sunlight that now goes to waste. The general effect will be to increase the **rate** of energy flux through the system of organic nature, with a parallel increase in the total mass of the great world transformer, of its **rate** of circulation, or both" (1956, p.357-8).

1195

EVOLUTION Horizontal and Vertical ²⁾⁴⁾

Chr.De DUVE, the Belgian biochemist, Nobel Prize 1974, distinguishes two different evolutive ways:

Horizontal: which creates **diversity** by variations on some basic type. De DUVE states that there are millions of insect species, but all are variations on the basic corporal plan of insects.

Vertical: which modifies the basic plan, adding to its **complexity**.

(Interview of Chr.De DUVE by O. POSTEL VINAY, 1996, p. 92)

This concept is basically referred to biological evolution. It would be interesting to find out if and how it could be applied to the **emergence** of **sociality** at different biological levels, and what it could mean for cultural diversity in human societies.

1196

EVOLUTION (Laws of) ¹⁾

D. DUBOIS recapitulates as follows the basic laws of evolution (1990, p.121-26):

1. **Fundamental biological law**: Embryonic **structures** of more complex **living systems** diverge by progressive specification from embryonic **structures** of less complex ones (von BAER, 1828; Haeckel, 1866).

2. **Growing complexity law**: In general terms, evolution leads to the **emergence** of more complex species, principally through the acquisition of a more complex nervous system.

3. **COPE's law**: Any lineage of species starts with small generic ones endowed with all the basic characteristics of the phylum.

4. **Diversification law**: Evolutive bursts take place, producing "bushy" ramification of more precisely adapted species, which become dependent of specific **environments**.

5. **Size increase law**: Most types tend to evolve toward an increased **size**, frequently leading to gigantism which difficulties further evolution when important **environmental changes** take place (H. DECUGIS, 1941).

6. **Take-over Law**: Evolutive **cycles** repeat themselves for each innovative biological type (orthogenesis), leading to either favorable **adaptations**, or neutral, or unfavorable ones.

7. **Irreversibility law**: Evolution never backtracks. Archaic forms never reappear once eliminated (DOLLO's Law).

8. **Evolution speed law**: In any group, the evolutive **rhythm** decreases as the group becomes older.

One could possibly add one more law: Evolution is radiative, but historically constrained, i.e. new types appear only as **transformations** from former ones or, no totally new evolutive lines start ever from "scratch" (M.C. MARNEY and N.M. SMITH, 1964).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

These are biological laws, but one wonders if they could not be translated to the evolution of **organizations** and **sociosystems** wherein some very similar **transformations** seem to be occurring through **time**.

1197

EVOLUTION OF COMPLEX SYSTEMS BY AGGREGATION: SIMON's Hora and Tempus Parable^{1) - 2)}

H. SIMON explains through his famous Hora and Tempus Parable how **complexity** may have evolved:

"Let me introduce the topic of evolution with a parable. There once were two watchmakers, named Hora and Tempus, who manufactured very fine watches. Both of them were highly regarded, and the phones in their workshops rang frequently – new customers were constantly calling them. However, Hora prospered, while Tempus became poorer and poorer and finally lost his shop. What was the reason?

"The watches the men made consisted of about 1.000 **parts** each. Tempus had so constructed his that if he had one partly assembled and had to put it down – to answer the phone say – it immediately fell to pieces and had to be reassembled from the **elements**. The better the customers liked his watches, the more they phoned him, the more difficult it became for him to find enough uninterrupted time to finish a watch.

"The watches that Hora made were no less complex than those of Tempus. But he had designed them so that he could put together sub-assemblies of about ten **elements** each. Ten of these subassemblies, again, could be put together into a larger subassembly; and a system of ten of the latter subassemblies constituted the whole watch. Hence, when Hora had to put down a partly assembled watch in order to answer the phone, he lost only a small part of his work, and he assembled his watches in only a fraction of the manhours it took Tempus.

"It is rather easy to make a quantitative analysis of the relative difficulty of the tasks of Tempus and Hora: Suppose the probability that an interruption will occur while a part is being added to an incomplete assembly is p . Then the **probability** that Tempus can complete a watch he has started without interruption is $(1-p)^{1000}$ – a very small number unless p is .001 or less. Each interruption will cost, on the average, the time to assemble $1/p$ **parts** (the expected number assembled before interruption). On the other hand, Hora has to complete one hundred eleven subassemblies of ten **parts** each. The probability that he will not be interrupted while completing any one of these is $(1-p)^{10}$, and each interruption will cost only about the **time** required to assemble five **parts**.

"Now if p is about .01 – that is, there is one chance in a hundred that either watchmaker will be interrupted while adding any one **part** to an assembly – then a straightforward calculation shows that it will take Tempus, on the average, about four thousand times as long to assemble a watch as Hora.

"We arrive at the estimate as follows:

1. Hora must make 111 times as many complete assemblies per watch as Tempus; but
2. Tempus will lose on the average 20 times as much work for each interrupted assembly as Hora [100 parts, on the average, as against 5]; and
3. Tempus will complete an assembly only 44 times per million attempts $(.99^{1000} = 44 \times 10^{-6})$, while Hora will complete nine out of ten $(.99^{10} = 9 \times 10^{-1}) / (44 \times 10^{-6}) = 2 \times 10^4$. Multiplying these three ratios, we get: $1/111 \times 100/5 \times .99^{10}/.99^{1000} = 1/111 \times 20 \times 20 \times 20,000 \sim 4,000$ " (1965, p.65-66).

Two conclusions are obvious:

- a) **complexity** results from ordered **aggregation of elements**.
 - b) **complexity** is more easily obtained by fractioned **aggregation**, from **level to level**.
- And a third conclusion is tentative:
- c) evolution very probably proceeds by fractioned **level of aggregation** to produce **complexity**.

Another interesting comment by SIMON: "...we may be sure that the watchmaker's **metaphor** gives an exceedingly conservative estimate of the savings due to hierarchization" (Ibid).

Of course, fractioned **aggregation** is related to **hierarchy**, as a result from **competition** between systems, destined to become subordinated and to undergo **processes** of internal re-organization of their **structures** and **functions** to adequate them to their new settings.

1198

EVOLUTION (Process of)¹⁾

J.P. CHANGEUX, quoting D.T. CAMPBELL, thus resumes the general process of evolution, that seems to operate irrespectively of the concerned evolutive **level** (physical, biological, social):

"At each **level** some form of *selective retention* would operate by variation-**selection** with three basic elements:

- some **mechanisms** introducing variations, i.e. **diversity generators**
- coherent **selection processes**
- some **mechanisms** which would protect and spread selected variations" (1972, p.707).

This last **mechanism** is **recursive**.

Another very general and synthetic view of evolutive processes has been derived from biological evolution by W. SCHWEMMLER (1991, p.152)

This author distinguishes three basic stages in these processes:

- Arogenesis: a **phase** of innovative jumps
- Allogenesis: a **phase** of adaptive **radiation**
- Statigenesis: a **phase** of **stabilization** of the new types

This general concept is clearly akin to GOULD and ELDREDGE "punctuated evolution" (1993). According to SCHWEMMLER, such evolutive processes respond to a "**periodicity principle**", which he relates to the well known HEGEL's principle of "These, Antithese, Synthese".

1199

EVOLUTION THEOREM²⁾

"Every **concrete system** belongs to some evolutionary lineage".

This theorem has been enunciated by R. MATTESICH in his "Axiomatic representation of the systems framework" (1982, p.184).

1200

EVOLUTIONARY LEARNING COMMUNITY (ELC)⁴⁾

"A community that strives toward sustainable pathways for evolutionary **development** in **synergistic interaction** with its milieu"(K. BAUSCH-glossary, pers. comm., 2002)

This goal should be pursued "through individual and collective **processes** of empowerment and evolutionary **learning**. ELC's do not adapt their **environment** to their needs, nor do they simply adapt to their environment. Rather, they adapt with their environment in a dynamic of mutually sustaining evolutionary co-creation"(Ibid)

These views have been developed during the years 1996-2000 in Fuschl and Asilomar **Conversations**. As a general program, the ELC indicates a genuine systemic evolutionary **path** for human communities.

However the practical **meaning** and content (also in systemic terms) of abstract **concepts** like "sustainable path", "development", "empowerment" and "learning" should be seriously researched and clearly explained if the whole ELC concept is to become more than an expression of well-meant wishful idealistic thinking.

→ **Communities (types of human); Evolution (Co); SyntonyQuest**

1201

EVOLUTIONARY ROBOTICS²⁾⁵⁾

The study of the **processes** of **evolution** and **co-evolution**, using **automata**

This study tries to reproduce in automata the evolutive processes observed through the history of **living systems**, in darwinian terms

The automata are endowed with some quite simple behavioral potentials as for example the capacity to move in certain specific ways, or to perceive at some distance the presence of an obstacle, which can be fixed or moving

The results of each **automata's activity** are registered into an **array** of artificial **neurons**, which dynamically interact and may produce behavioral **changes** in the automata. This leads to a spontaneous process of evolution (and co-evolution) between two or more automata) This process may persist indefinitely in time. Some automata of this type can **simultaneously** undergo evolution in their **neuronal circuits** and their **morphology** (D. FLOREANO, 2002, p. 24)

→ **Artificial life; Epigenesis; Evolution (Co-); Machina Speculatrix; Parallel Distributed Processing; Self Organizing Systems; Selection**

1202

EVOLUTIONARY STABLE STATE ²⁾

A global state of a **set** of interrelated evolving systems such as their global **equilibrium** can not anymore be modified by any **change** in any of the systems.

This **model** has been created by mathematical biologists, in particular John Maynard SMITH (P. BAK, 1996, p.125)

It appears in Economics, as the "**Nash equilibrium**" and reflects a very general **situation** corresponding to evolutive blockage. However such apparently final **state** can be ruptured. But the conditions leading to a renewal of **evolution** are not yet clear.

→ **Co-evolution, Fitness, Frozen core, NK model.**

1203

EVOLUTIONARY SYSTEMS DESIGN ⁴⁾

"A form of **systems design** that responds to the need for a future-creating- design **praxis** that embraces not only human interests and life-spans but those on planetary and evolutionary planes as well. The primary vehicle for the implementation of ESD is the **Evolutionary Learning Community**" (From a Glossary prepared by Ken BAUSCH for ISSS, 2002)

1204

EVOLUTIONISM ^{1/3)}

The belief in evolutive **models**.

The scientific theory of **evolution** (E. SCHWARZ, 1993, p.5), ... which is quite a different matter.

SCHWARZ adds a complementary definition in order to discuss more widely the general concept: "A philosophical attitude based on evolution". He writes: "Evolutionist **theories** may have different **connotations** according to the disciplines. In natural sciences, evolutionist **models** (irreversible thermodynamics, non-linear dynamics modelization of emergence and complexification in physics; Darwinism or Lamarckian transformism in biology) have positive **connotations** in comparison to **models** without a privileged **time** direction (classical

mechanics), or fixist ones (creationism) in biology. On the contrary, in human sciences (ethnology, **sociology**, anthropology, etc...) evolutionist **theories** appeared during the colonial period, associating the **evolution** idea to **progress** (transition from the "savagery" to the "civilized" state). As a reaction other **models** appeared more recently in which the **time** problem has been sometimes abusively eliminated" (1993, p.6)

In short the evolutionist concept covers quite different **meanings**- and even intentions or prejudices- and should be carefully scrutinized wherever it appears

1205

EVOLUTIVE ACCELERATION ¹⁾

F. MEYER dedicated an important book to the global problems of evolution, with an intriguing chapter on "Evolutive acceleration" (1954, p.173).

Various other authors did observe that many evolutive **phenomena** of very varied kinds seem to accelerate with **time**.

F. MEYER, in "La surchauffe de la croissance" (1974) emphasizes this **process**, at work in **growth** of the number of living species and the cephalization index of animal species; growth of human **population** planetary wide; of **population density** by square kilometer; of the length of cutting edges per kilo of stone from early paleolithic to late neolithic; of appearance of new types of tools during the same **time-span**; of urban concentration; of the quantitative use of **energy**; etc...

MEYER describes also some general and striking characters of these **phenomena**:

- Not only does acceleration take place, but altogether an acceleration of acceleration, which produces logarithmic and even in some cases hyperbolic **growth**.

Figure: see entry **EVOLUTIVE ACCELERATION**

Evolutive acceleration: Velocities

A. motor car; Av. Aircraft; H. Sea plane; R. Jet

(Note: This curve dates back 1953. Today Space rockets could be added)

From. F. MEYER: 1954, p. 71

- The mechanics of acceleration is a positive **feedback** (see figure).
- The hyper-acceleration **process** should normally be self-destructive.
- However, there is a relay **mechanism** by which, when the evolutive curve of a **phenomenon** starts to accelerate, some new **phenomenon**, more powerful, appears. As an example MEYER uses the **growth** of human displacement velocities from the old horse postal express up to the rocket. Today, he could add the interplanetary explorers.
- There is an evolution of evolution characterized by curve-embedding

MEYER gives the following cybernetic explanation of the acceleration **phenomenon**: (1974, p. 550)

see figure next page

H. SIMON viewed the **phenomenon** from the angle of **complexification mechanism** and his argument explains the existence of the evolutive relays noticed by F. MEYER:

"Using the simplest hypotheses, the **time** needed by a great system to its spontaneous build-up starting from its "atomic" **components**, grows geometrically according to the number of its **components**. On the other hand, if a **hierarchy** exists of potential **subsets**, with more or less the same number of **components** on each **level**, then the **time** needed to constitute a system of **n elements** grows only according to $\log_n$. In other words, when big systems are built according to this **hierarchical method**, the doubling in **size** of the bigger evolving systems will be more or less constant. It may be expected that systems of size 100 evolving in an **environment** of size 50 systems will do it more or less within the same span of **time** as size 50 systems evolving in an **environment** of size 25 systems" (1990, p.134).

We will thus witness a logarithmic **growth** of the **size**, and probably the general **efficiency**

Figure: see entry **EVOLUTIVE ACCELERATION**

a. Positive feedback (m_{t+1}) of growth on the growing mass (m_t) (rate in %): exponential evolution.
 b. Same case, with negative feedback on the operator: logistic evolution.
 c. Same case, with positive feedback on the operator: self-accelerating hyper-exponential evolution.

of systems in similar lapses of time.

F. MEYER gives still another interesting insight. He hypothesizes that the general evolution process started on the morphological level and passed successively through the physiological and the behavioral one, reaching finally the technical one. This is related to the evolution of the brain: first global, next of its superior centers and finally of the cortex. (1954, p.174). In other words, evolution affected first material processes and is now acting on the information level, using energy in a quite more efficient way.

The topic has also been considered by C. BRESCH (1977) and H.von FOERSTER et al. (1960)

1206

EVOLVABILITY⁵⁾

"The capacity of genes to mutate and modify an organism's genotype without jeopardizing its fitness" (C. KOCH and G. LAURENT, 1999, p.96)

The authors write: "Evolvability should be favored by organismic compartmentation, redundancy, weak and multiple (parallel) linkages between regulatory processes and, finally, component robustness. These features all imply that evolution can only tinker with a system successfully if many of its constituents and coupling links are not essential for survival of the organism"...

Applying this to the brain, they state that it should be "... replete with specialized circuits, parallel pathways, and redundant mechanisms" (Ibid)

The evolvability concept is also probably significant for evolving complex social systems, specially the **man-planet system** presently in process of **organization**.

The author's comment is related to the evolutive path that led to the shaping of the highly organized mammalian and human **nervous system** and, particularly **brains**.

However, the concept and its shades of meaning seem to be generally applicable to any evolving system, including social **organizations**.

1207

EXAPTATION²⁾⁵⁾

Any **adaptation** that results of the posterior use of some feature arisen formerly

This neologism (I. TATTERSALL, 2001, p. 45) refers to the evolutive **emergence** of new useful **functions** in living beings which use some randomly appeared features which had no obvious utility to begin with.

He writes: "This is a useful name for characteristics that arise in one **context** before being exploited in another, or for the **process** by which such novelties are adopted in **populations**"

And "the classic example of exaptation becoming **adaptation** is birds' feathers. These **structures** are essential nowadays to bird flight, but for millions of years before flight came along, they where apparently used simply as insulators (and maybe for nothing much at all before that)" (p. 43)

Tattersall gives another example:

"...we have no idea at all about how the **brain** converts a mass of electrical and chemical **signals** into what we are individually familiar with as **consciousness** and thought **patterns**" (ibid. p. 45)

1208

EXCHANGE¹⁾

A reciprocal **flow** of **matter**, **energy**, **information** or any other commodity between two systems or **subsystems**.

Exchange is necessarily submitted to **rules** or **constraints**. It can be equal or unequal, permanent or **periodic**, steady or variable.

It supposes a convenient **communication** system.

1209

EXCITATION¹⁾²⁾

The triggering or more or less sudden increase of some **process**.

The excitation **agent** is a **stimulus**, i.e. a new or increased **input** received from the **environment** or by priming through a **positive feedback**.

Excitation is a very general **phenomenon**, that can be observed in many physical, chemical, biological, ecological, economic, psychological and social processes.

In many cases the excitation process is coupled with an **inhibition** process. their alternance allows the system to maintain itself in a restricted **range** of **stability** conditions. Excessive or too frequent excitation in some process may lead to crossing a threshold of unstability and destroy the system if not compensated in due time.

→ **Catalysis; Constraint; Far-from-equilibrium condition; Instability; Oscillators; Periodicity; Stability (Poly-)**

1210

EXCLUSION (Competitive)⁵⁾

Two species which have identical **ecological** requirements cannot long coexist in a **habitat**.

This principle was introduced by G.F. GAUSE (1936).

J.de ROSNAY proposes to replace the notion of "natural **selection**" by the one of "competitive exclusion". In his wording: "**Self catalysis** unavoidably triggers quick **growth** and acceleration; but altogether **conflicts** with the **environment**. The growing systems drain **energy** for their own use. When the **environmental resources** are limited, these systems start to compete with others. Some survive, others are eliminated.

"In this perspective **self catalysis** and **self selection** become connected. Natural **selection** cannot anymore be confused with some arbitrary **choice** made from "outside" by a supranatural entity, nor even with an **environment** endowed with some hypothetical "project". The old notion of "natural **selection**" must thus be replaced by a more general one, which integrates duration and acceleration, namely "competitive exclusion" (1975, p.230).

Various growing systems can rival to obtain scarce **resources** of **matter**, **energy** and **information** and some of them may eliminate some others. However, in a global **environment**, they all finally depend on each others. Thus a succession of imperfect and transitional **dynamic equilibria** takes place among them all. Such a **situation** is found for example in **ecology**, as well as in economy and, as noted by de ROSNAY, is in accordance with ASHBY's **Law of Requisite Variety**.

The value of the principle seems thus quite general.

1211

EXCLUSION (Mutual)⁵⁾

In a **network** of computers, "the property that the steps of one operation cannot be interleaved with steps of another" (P. DENNING, 1991, p.111).

According to P. DENNING: "One of the most fundamental requirements in all... (**networks** of computers) is that certain **operations** be indivisible: the **operations** must be carried out in some definite **order**, one at a **time**, even when different computers request them simultaneously. If, contrary to this requirement, the instructions of one **operation** were interleaved with those of another, the results would be unpredictable. Deposits and withdrawals could be lost; confirmed reservations might disappear, **parallel processing** computers could produce invalid **outputs**."

"Because indivisible **operations** are not allowed to be in progress simultaneously, we say that they are mutually exclusive" (Ibid).

It can be seen that the **simultaneity** problem is all-pervasive.

As **simultaneity** destroys perfect causal **determinism**, no perfect **algorithm** seems possible in **parallel operation**.

1212

EXCLUSION PRINCIPLE⁵⁾

If two particles occupy the same region in **quantum** space, they cannot be in the same quantum state. This means that the values assigned to the quanta numbers that characterize them must be different for different particles.

This principle was enunciated in 1925 by the Austrian-American physicist W. PAULI (1900-1958)

1213

EXERGY¹⁾

"That part of **energy** that can be used without limitations" (Diccionario RIDUERO de Ecología, translation of the "HERDER Lexicon Umwelt, 1973).

1214

EXOGENOUS¹⁾

Deriving from outside the entity or system.

Exogenous conditions or factors are considered only because they somehow impinge on the system.

1215

EXOSOMATIC INFORMATION¹⁾

The information created and eventually retrieved by **living systems** in, and from their **environment**.

This concept has been developed by S. GOONATILAKE (1992, p.83-117): "While almost all **memories** are internal in the **brain** of animals, external **memory markers** are sometimes used as cues for the internal functioning of the **brain**. Sometimes such "**memories**" are consciously created and externalized in the world outside the **brain**. Sometimes the external **memories** can be manipulated" (p.83).

The marking of territories by animals is already a form of exosomatic information. There is also a close relation with **stigmergy**. In human societies, exosomatic information became an "explosive" **process**. Men rely heavily on a growing number of non-biological external clues and devices to sustain their evermore complex **organizations**. Moreover, as noted by GOONATILAKE, exosomatic **processes** can now be manipulated and are even seemingly acquiring a kind of autonomous **activity**, through spontaneous **self-organization**, particularly in **information networks** (p.120).

1216

EXOSTRUCTURE²⁾

The **set of connections** of a system with **elements** or systems in its **environment** (Adapted from M. BUNGE, 1995, p.15).

According to BUNGE, this exostructure includes the **inputs** and **outputs** of the system and, together with its internal **structure** (which he calls **endostructure**), it constitutes the total **structure** of the system.

It seems that the exostructure is more variable and less constraining than the endostructure. For example, the internal temperature of a mammal is a much more rigorous **constraint** than the **range** of tolerable temperatures in its **environment**.

1217

EXPERIENCE (Axiom of)^{1) - 3)}

"The future will be like the past, because, in the past, the future was like the past".

This ironical so-called "axiom" by G. WEINBERG is a "wolf in sheep clothes". Our **knowledge** of the past is always quite relative and we now understand why this is so: **Deterministic chaos** in complex **situations** makes practically impossible not only a perfect prediction of future but altogether a complete **understanding** of the tangle of **causes** that produced some past **event**.

We thus can never be sure that a present **situation** apparently similar to a former one will evolve in exactly the same way.

1218

EXPERIENCE (Law of)¹⁾

"**Information** put in by **change** at a **parameter** tends to destroy and replace **information** about the system's **initial state**" (W.R. ASHBY, 1958, p.139).

This law seems somewhat contradictory with the basic concepts of **autopoiesis** and **organizational closure**, which correspond to dynamically stable systems.

On the contrary, it seems to fit better with **chaos** concepts and possibly finds an illustration in **FEIGENBAUM's number**.

1219

EXPERIENCE LOOPING^{1) - 2)}

The use of permanent **feedback** between producers (inventors, researchers, engineers, managers, etc...) and users (servicing technicians, clients).

This **cybernetic methodology**, proposed by M. MARUYAMA (1985, p.385-89) aims at successful product invention, development and **adaptation**.

It allows for better **information** about the variable and specific conditions of a technique's use in different physical and human **situations**.

It includes **design** looping, in which "the **components** are re-designed for the final product, and, **concept** crossing which "is the combination of concepts from different fields of specialization (in which **process**)... much foresight is needed on the part of the **management**" (p.387).

MARUYAMA gives some impressive examples in his paper.

1220

EXPERIENTIAL FIELD^{1) - 3)}

The total extension of all what an **observer** is able to register after having received a specific training.

As stated by E.von GLASERSFELD the **observer** extends his/her experiential field "... using the **invariances**, **rules**, and **concepts** he/she has constructed for him/herself in the course of his/her past experience" (1976, p.118).

1221

EXPERIENTIAL STATE²⁾³⁾

A fleeting state of the **brain** that results of the interaction of "sensory **perceptions**, **memories** and emotions"(after F. CAPRA, 1997, p. 292)

Capra thus reproduces MATURANA and VAR-ELA's concepts about the way we connect with the "real"world. Such experiential states produce a "unitary mental space", but "the experience is not constant...and may be extremely short"(Ibid)

Capra explains "...transitory experiential states are created by a **resonance phenomenon** known as "**phase locking**" in which different brain regions are interconnected in such a way that all their **neurons** fire in **synchrony**. Through this synchronization of neural activity, temporary "**cell** assemblies are formed, which may consist of widely dispersed **neural circuits**"(p. 292)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1222

EXPERIMENTAL FRAME²⁾

"A set of **variables**, their **state set** with appropriate **observation channels**, **time** (as a **parameter** within which the **variables** are observed), and an appropriately defined **time set**" (G. KLIR, p.151, 1988).

Obviously, the experimental frame *determines* what we are going to register, at which **level** and in function of which implicit or explicit **methodology of inquiry**.

As to the **time set** for example, it is not indifferent whether the observations are made every second, twice a day or once a year.

→ **Reconstructability analysis**

1223

EXPERIMENTAL NEUTRALITY¹⁾

Such a kind of neutrality is advocated by P. CHECKLAND and his followers. The neutral researcher is supposed to enter the field without preconceived theories or **models**, i.e. with a to-tally open mind.

While this is obviously an excellent proposal, it is however quite difficult to practice. Our more deeply engrained preconceptions (or prejudices) are precisely the most difficult for ourselves to become conscious of (de ZEEUW's "**invisibility**") and to take care of in our **interaction** with the problem we tackle. There exists thus no such thing as a neutral **observer-actor** and a healthy beginning should probably include a kind of "declaration of personal prejudices" ... if we become ever capable to do that.

1224

EXPERIMENTALISM^{1) - 3)}

A **methodology** of inquiry that assumes the indissoluble interconnection between **facts** and scientific laws.

Experimentalism has been proposed by E.A. SINGER Jr. and developed by C.W. CHURCHMAN and R.L. ACKOFF.

In their overview of experimentalism, G.A. BRITTON and H. McCALLION write: "All **knowledge** of law implies **knowledge** of **fact**, all **knowledge** of **fact** implies **knowledge** of law. For experimentalists there are no fundamental **truths**. Some laws have to be assumed in order to learn, but in addition, some **facts** have to be known in order to generate laws. **Facts** and laws are inextricably intertwined, they cannot be separated. **Truth** is not the starting point of **inquiry**; it is the end point" (1994, p.490).

This is coincident with the **autopoietic** view of the **observer**: **perceptions** as well as **concepts** are closely linked within the **observer's organizational closure**.

According to C.W. CHURCHMAN, the "original question becomes more and more complicated, *not* simpler and simpler. This **learning** "more and more" is what, following SINGER, I call the "sweep-in process" of **systems science**" (1981, p.1-2).

Some important results of this approach are:

- 1) no science is more fundamental or important than another;
- 2) experimentalism moves the attention away from what scientists *actually do* to what *they ought to do* and
- 3) experimentalism assumes a **teleological** view of the world (1994, p.491).

Experimentalism breeds a method of insight and intuition and, in the case of CHURCHMAN, an **ethical** view of science: The **meaning** of reality is an ideal to be pursued.

1225

EXPERIMENTATION SPACE³⁾

A mental and physical space "... created in order to allow for **design** experimentation and the testing of emerging **design** alternatives as well as the **assessment** of the on-going **design** itself" (B. BANATHY, 1988, p.33).

This is an important feature of BANATHY's concept of **design**, because it results in **design** not being a closed-off or unduly restricted **domain**.

1226

EXPERT SYSTEM⁵⁾

A computer **program** able to resolve some problems in a way comparable to an expert or a group of experts.

An expert system includes a **data** bank and **rules** to use them. The **rules** are constructed by "**knowledge engineers**" who extract the **knowledge** considered relevant from conversations with human experts and transform them into "production **rules**" usable in a computer to compare and interconnect **data** in significant ways, in order to produce useful conclusions. This is obtained through an "inference engine" which establishes coordinated general ways to apply the production **rules** to **data** corresponding to any specific case. This leads to the shaping of a **decision tree**.

The classical expert systems are thus typically **algorithmic**, but they ultimately depend from human expertise. Nevertheless, the more advanced **connection machines** permit the use of inductive **programs**, using "... a purely logical approach to *find* abstractly defined regularities in the **data**, irrespective of subject-matter" (M. BODEN, 1991, p.186).

Thus: "A **learning program** that uses this logical strategy can structure a *classification-by-property conceptual space* in the most economical way, and can find the shortest pathway for locating examples within it" (Ibid).

The **rules** collected in an expert system may also represent the **consensus** making **process** between different objectives (See ELF Supplement - New Scientist Vol 138 - n° 1870 - 04.24.93, p.7).

ELF Company applied the following features in its GRANDPUITS refinery in France, for refinery **automation**.

The proposal was to ensure the quality of production, as well as the long life of the unit, but also taking in account the action required to run the plant on a day-to-day schedule. This included:

"... on the spot analysis of the **behavior** of each **part** of the unit;

" **decision-making**, in order to create a **control strategy** taking into account the **time** factor of the **actions**;

" more detailed **control** procedure with the **commands** routed to the **controllers** throughout the **network**.

"This required that the system be fully integrated in the **real-time environment**" (Ibid).

Expert systems are designed within the technical perspective and so, are weak or useless for the organizational or societal perspective, and still more so for the personal perspective (I.I. MITROFF and H.A. LINSTONE, 1993, p.105).

1227

EXPLANATION³⁾

"Any theory that logically implies,... reconstructs or generates what has in fact been observed" (K. KRIPPENDORFF, 1986, p.30).

M. BUNGE (as quoted by J. CASTI, 1990, p.38-40) distinguishes causal and noncausal explanation and typifies them as follows:

Causal explanations

- a) Inclusion in a sequence
- b) Tracing origins and **evolution**
- c) Connection with other **facts**
- d) Analysis

Noncausal explanations

- e) Membership in a **class**
- f) **Description**
- g) Static **structure**
- h) Reference to a lower **level**
- i) Reference to a higher **level**
- j) Statistic
- k) **Teleology**
- l) Dialectic

CASTI comments: "Causal explanation will be found only within the laws of science and nature, not outside them. In short, scientific explanation is explanation by law, not by **causes**" (p.40).

Explanation (Systemic)

More specifically, systemic explanation rests on a **systemic epistemology**, based on general principles related to observational conditions and conceptual construction. It also uses general **isomorphic models** that can be applied to describe a great number of similar **processes** and **structures**.

Systemic explanation does not suppresses nor supplants traditional rational and scientific explanation, as it is directed to a different type of **objects**. It merely creates a wider **frame** within which they become included and can still be used when specifically efficient.

However, to round up in a more skeptical and general mood, BATESON believed that any explanation simply connects two statements in a **semantic** way. This is the case for any explanation, but it leaves always open the possibility that one must in the end accept or reject such semantic arrangements as bona fide "explanation" (within brackets!)

→ **Purpose**

1228

EXPLOSIVE PROCESS^{1) - 2)}

A self-destructive process resulting from a constantly recurrent **positive feedback**.

Any process must be fed by some kind of **inputs**, whether material, energetic or informative, obtained from an **environmental source**. As **positive feedbacks** produce a major need of **inputs**, the accumulative acceleration of their use tends to an also accelerated exploitation of the **source**, leading to over-exploitation or **overburdening**. This in turn leads the process to a **runaway event** that leaves it (and the system it belongs to) more or less quickly without the needed **inputs** (or **outputs outlets**, or **sinks**) and ends up in its destruction.

The same **phenomenon** may also lead to internal **overload**, or in **populations**, to **overcrowding**. Paradoxically, such **overload** is conducive to a kind of de-synchronization and lysis of the normal **interactions network** and to the uncoordinated dispersal of the members of the **population**. (B. WALLISER, 1977, p.84).

1229

EXPLOSIVE-IMPLOSIVE PROCESS^{1) - 2)}

A process of expansion that reaches a **limit** and is replaced by a process of contraction.

This is a result from an over-exploitation and exhaustion by the system of the **source of inputs**.

It is different from the explosive-destructive process although it may also finally destroy the system. It is also different from **logistic growth**, where a **damping** or braking **feedback** leads the system to a **situation of asymptotic or dynamic stability**.

R. VALLÉE describes a mathematical formalism for the explosive-implosive process (1995, p.63-5).

1230

EXTERNALITIES¹⁾

The **set** of factors that do not seem to influence significantly a system or some of its **processes**.

This is a very deceitful concept, specially in economics, because externalities are defined according to a set of generally uncriticized principles or **rules**. Moreover, as systems become wider embracing, more and more externalities should be taken in account as significantly related to them.

There is also a **long-term trend** aspect. Some factors, for instance the slowly accumulative ones, do not manifest their impact for decades or centuries and thus are classified as externalities... unless suddenly they introduce unexpected **disturbances** (or offer new opportunities).

According to K. KRIPPENDORFF: "Externalities may also be regarded as the nonanticipated **side effects** of calculated courses of **action**" (1986, p.30).

It could be better to speak of *ill-calculated* courses of **action**, generally because of a non-systemic partialized view of the **situation**.

1231

EXTERNALIZATION¹⁾

The shift from strict biological **control** in **living systems** to a measure of psychic and social **control**.

S. GOONATILAKE speaks of **exosomatic information**, based on cultural **interrelations**. According to him: "Animals interact with the **environment** using a wide **variety of input and output channels** such as chemicals (f.ex. pheromones), acoustical and electro-magnetic waves and mechanical intervention with the **environment** using limbs and such devices as tools" (1991, p.83).

This amounts to be able to "reading" clues in the **environment**, as in **stigmergy**, or through **positional values**.

What GOONATILAKE describes as the exosomatic sphere, in the case of humankind, is presently in a **process of evolutive acceleration**, through the exponentially growing number of **artefacts** created by technological man. However these **artefacts** also increasingly *control* human societies.

1232

EXTINCTION¹⁾

The complete and definitive disappearance of a **class** of systems.

Extinction, as a general concept, express that some **class** of living beings or **organizations** has become unfit in a transformed **environment**, because it could not evolve to readapt to changed conditions.

It is a systemic concept, since it can be applied to dinosaurs, archaic cultures, feudal principalities, or stagecoaches, or even possibly **living systems** in planets becoming unfit for life. Extinction is heralded by the progressive

reduction of the number of members of the **class** and/or by **critical changes** in the physical, ecological, technical, economic or socio-political **environment**.

1233

EXTRAPOLATION¹⁾

The inference of **forecasts** or unknown **information** from historical **trends**.

Extrapolation is, from the systemic viewpoint, one of the most risky method at hand. It supposes the unperturbed continuity of existing **trends**, and even the correctness of the **evaluation** made of the latter.

It implies the beliefs: 1) that the **relationships** between relevant **variables** will remain **stable** (i.e. that the system is basically **linear**); 2) that long or extra-long **trends** are effectively known (f. ex. the multi-secular **oscillations** in climate); 3) that no ignored or new factor could influence the system (f. ex. the appearance of sporadic and ulterior **runaway** resistance of insects to insecticides).

Catastrophe theory, as well as **chaos theory** and **dissipative structuration** show that extrapolation has very narrow limits as a predictive technique.

1234

EXTRAREGULATOR¹⁾

A system which is able to adapt to a point its **environment** to its internal needs for **constancy**.

This concept was introduced by G. BATESON as complementary to those of "**adjustors**" and "**regulators**". He wrote: "... the polarity between **adjustors** and **regulators** can be extrapolated another step to include what we may call 'extraregulators' which achieve **homeostatic controls** *outside* the body by changing and controlling the **environment** - man being the most conspicuous example of this class" (1973, p.332).

Social insects (as well as a social mammal, the naked mole rat) also achieve extraregulation, at least up to a point, by creating their own artificial **environment**.

E. JANTSCH observes that this "...centrifugal evolution is favored by **variable stress** and thus incorporates a basic principle of **nonequilibrium** and **fluctuation**, whereas constant **stress** would favor a centripetal direction of **evolution**" (1976, p.55).

1235

EXTREME VALUE THEORY²⁾

A **forecasting set of models** that can be used to predict the likelihood of extremely rare **events**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The theory is based on **distribution** curves (Gumbel, Fréchet and Weibull curves) which give "a precise quantitative statement of the otherwise vague notion that the more extreme the event, the less likely it is to happen" (R. MATTHEWS, 1996, p. 37-38).

The theory has been developed by R. SMITH (Univ. of North Carolina) and L.DE HAAN (Erasmus University, Rotterdam).

It offers no real possibility of precise **predictions** but is useful for determining the most extreme possible events in accordance with statistics of lesser similar events in the past, on a long **time scale**.

Dutch experts have found for example that the maximum known historical flood due to a North Sea storm in Holland has topped 4 meters above sea **level** (in 1570). It has thus been estimated that walls of 5 meters upon the sea level should meet a criterion of a once in 10 000 years flood. (see GOLDENFELD and KADANOFF, 1999, p. 87)

Other examples are volcanic eruptions, big earthquakes, crashes in stock markets, **epidemics in populations**, hurricanes in the Caribbean zone, the "El Niño" **events** in the Pacific Ocean. **Intermittence** generally implies sudden paroxysmic **changes** or an epochal **reversal** in-between variable but long **relaxation periods**. It is related to **synergetic processes**, **power laws**, and **dissipative structuration**, all of these probably governed by great **fluctuations of energy inputs**, or their cumulative **long term effects** (ibid, p.87-89).

→ **Numbers (Prime); Periodicity; Term (short-, medium-, long-)**

1236

EXTRUDER ^{1) - 2)}

"The **subsystem** which transmits **matter-energy** out of the system in the form of products or **wastes**" (J.G. MILLER, 1978, p.3).

The extruder is one of the **20 critical subsystems** in MILLER's **taxonomy of living systems**.

F

1237

FACILITATION ^{4) - 5)}

The use – by a facilitator – of a array of material, computer and/or intellectual and behavioral techniques in order to help a **group** to overcome difficulties in grasping complex **situations** and designing.

Facilitation is a practical necessity in any **group** concerned with the **evaluation** of complex **issues** and **situations**, **design** and **management**.

However, the facilitator needs a specific training in **Group technique**, **Interactive Management** or **Co-participative Design**. He/she should not, as facilitator, interfere with the **group's activity**, and still less acting as an overpowering "leader".

1238

FACTOR (Co-) ¹⁾

A secondary **cause** or circumstance that contributes to the permanence or **change** of some **process** or **situation**.

Co-factors should be monitored because they can nudge the **process** or system toward a critical **threshold**, while they are frequently ignored, overlooked or underrated.

1239

FACTORIALITY ¹⁾²⁾

Factorial multiplication of combinations between **elements** is obtained through the product of all positive integers from 1 to n, n. being the number of elements intervening in the combinatory.

This is represented by n!, as a short hand for 1.2.3...n.

Obviously, the number of possible combinations among elements grows in an accelerated way in accordance to the number of elements in the combinatory.

This is however an abstract **model**; it is implicitly admitted that there are no restriction of any kind for some combinations.

In practical situations such restrictions appear promptly because for ex. of **environmental** limitations that block or brake the multiplication of the elements, or through **saturation** of their relational **network**.

→ **Combinatorics**

1240

FACTS as CONSTRUCTS ³⁾

K. KRIPPENDORFF defines a fact as "Anything described and held to be true". He also contrasts facts with statements that may be "untrue, surmised" or hypothetical, or reflect fantasies or beliefs (1986, p.30).

Coincidentally G. BATESON states: "There are, in a sense, no facts in nature; or, if you like, there are an infinite number of potential facts in nature, out of which the judgment selects a few which become truly facts by that act of **selection**" (1973, p.456).

St. BEER puts in the following words: "Science is supposed to amass "the facts" and then to form hypotheses based on those facts. But the hypothesis is already covertly implicit in the **selection** of the facts, and further selection of a less than overt nature occurs during the **process** of elaborating the hypothesis further.

The continuing **operation** is **circular**. That is why cybernetics takes *ouroboros*, the snake that bites its own tail, as a suitable logo, and talks about **circular causality**" (1999, p. 441)

It could be said that a fact is something that can be observed, perceived and understood within a conceptual **frame of reference**, which serves mainly to define facts in function of **contexts** (which can be shifting in **time**, as shown for example by astronomical "facts" from Ptolemaic to Einsteinian viewpoint, through Keplerian and Newtonian ones). T. SANDOZ writes: "A fact becomes observable at the moment that it becomes interpretable"... and interpretations can be variable: an earthquake is a disaster for the affected people, but for the geologist, it is a manifestation of plate tectonics. Moreover, "A fact is nothing without a theory" (1993, p.1544)... i.e. any "fact" contains an implicit theory. That would be true also for archaic myths, considered as explanations based on a **class** of proto-theories.

Now, how do we select our facts?

What we call "facts" are merely **constructs** of our **brains** elaborated from our **perceptions** of "things" or **events** "there outside" and their **processing** by our neural **networks**. Moreover, anyone selects his/her facts according to the personal **organization** of his/her cerebral **networks**, as it resulted from training and **learning**.

As argued by P. DENNING: "Science is a **process** of constructing facts" (1990, p.102). It is not the only one, but it is the most reliable, because it is solidly based on non-contradictory **coherence** and possible refutation (POPPER).

Facts are thus merely "facts": They are basically a possibly provisional **consensus** on some **representation** of "something out there" and should not be given an absolute and definitive value. In the words of the French physicist B. d'ESPAGNAT "reality is veiled" (1979). This caveat is a much needed self-protection against many delusions.

1241

FAILURE TREE ²⁾

An analytical **graph** which seeks in a deductive way to determine the basic elementary **cause** of a failure in some device.

The tree is constructed by sequential elimination of the sections of the **process** which are not responsible for the failure.

Of course, the correct initial **selection** of the failure in precise terms is a requisite condition for the construction of a useful tree.

The enquiry use the logical door "or" at every discriminating **distinction** in the **process** of construction of the tree.

The **analysis** should be ended when the cause of the failure is identified at the operative **level** at which an intervention is practical and sufficient.

→ **LUSSER theorem**

1242

FALSE PEAK→ **Optimum (Local)**

1243

FALSIFIABILITY³⁾

"Capacity of a theory to generate a test which, if failed, refutes the theory" (R. FIVAZ, 1991, p.32).

This epistemological concept – also known as "refutability" – has been introduced by K. POPPER.

D. BOHM and F.D. PEAT explain: "Repeated experiments, made on the basis of a theory's predictions, will certainly increase its credibility among the scientific **community**, but they can never *prove* its correctness in any absolute sense. All theories are in some way limited, and while a series of experiments may confirm the theory in some limited **domain**, they cannot rule out the possibilities of exceptions and novel **behavior**. The best that science can do, therefore, is to falsify a theory by establishing some significant point of **deviation** between experiment and prediction" (1987, p.58).

R. FIVAZ observes however: "General theories such as **thermodynamics**, often do not specify completely how they are to be applied; therefore, they are immune to test by reality and consequently unfalsifiable" (Ibid).

This is also the case of so-called **General Systems Theory**... insofar as it may really be considered a "theory".

This is an intriguing point. In fact, it would seem that the falsifiability **criterion** can be applied in a strong sense only to classical and narrowly specific **deterministic** theories. In M. BUNGE's words: "Evidently, the more general a theory, the wider the **domain** of **facts** it refers to, and the less testable it is" (1993, p.221).

True or false is in such a case a too narrow **dichotomy** and testability *in these terms* an off the mark **criterion**.

Could *models* (as for example **catastrophe** or **chaos** ones) be either proved or disproved?

From a strict **semantic** viewpoint, the very term "falsifiability" seems unfortunate, as, for superficial minds, it seems to introduce the notion of falseness. However, neither the corpuscular, nor the ondulatory theory of light have been recognized as "false": they merely became integrated within a more general embracing theory.

For a short and very readable synthesis about "thinking about thinking" and an **evaluation** of POPPER's falsifiability, see M. CROSS (2000)

1244

FALSIFICATION (Cross)³⁾

A practical way to falsify (in POPPER's sense) theories about the workings of natural systems.

Such a **method** is proposed by M. CHRISTIE (2001) because complex natural systems cannot be subjected to experimental **control**. Even **computer simulation** may be inconclusive because it depends on the characters of the **model**, as derived from the set of hypothesis. Moreover the **computer model** may in part result of **choices** dictated by computational logical (**binary**) necessities.

CHRISTIE states that only cross-falsification is useful, i.e. by creating an interplay between two antithetic theories (for ex. that chlorinated components produce the ozone hole, or that they don't).

If they demonstrably do not, some other explanation should be found and different **forecasts** about the respective **effects** could be proposed. The observed **deviations** from the respective **predictions** should reveal the real superiority of one theory over another.

1245

FAMILY THERAPY⁵⁾

A current in psychology and psychiatry based on systemic concepts, mainly centered on **autopoiesis**.

Familiar therapists rejects the "**Olympian stance**", common in their trade, which induces most psychologists and psychiatrists to believe that they can treat their patients only on the bases of **objective observation**; generic concepts about some **classes** of mental illnesses and some **objective guiding** of the patients.

Familiar therapists try to better understand what "being an **observer**" implies and, as a result, they consider that their **interactions** with the patients are not neutral. Moreover, they believe that no patient can be isolated from her/his personal **environment**, and, more specifically from her/his family, which generally presents psychological **closure**.

The therapist interventions aim at a better **integration** of the whole family **group**, including a better **adaptation** of its members **behavior**.

1246

FAMINE→ **Net (Access problem in a net)**

1247

FANNING²⁾

A synonym for "**branching**"

1248

FAR-FROM-EQUILIBRIUM CONDITION^{2) - 5)}

The condition of a system undergoing widening **fluctuations** that leads it close to an **instability threshold**.

I. PRIGOGINE describes it as follows: "Here the **fluctuations** may be amplified and change the **macroscopic pattern** of the system. The **state** of the system extrapolated from the **equilibrium state** becomes unstable and, through **fluctuations**, is driven into a new **state**. **Instability** means that under these conditions existing **structure** cannot be maintained: the system has now become open to... a multiplicity of new possibilities and the phenomenological equations... cannot predict which of the new possibilities will be realized. **Evolution** of the nonequilibrium **structure** depends on some singular **factor** that happens to occur at the right time, at the right place: it depends on **chance**" (1984, p.48).

1249

FATAL EMBRACE→ **Net (Access problem in a)**

1250

FEASIBILITY (Cultural)⁴⁾

The effective possibility (or impossibility) to implement some economic, social or political **change** in a specific cultural setting.

Many projects, under others so-called **development** projects, are elaborated by members of one **culture** for implementation in another culture. In numerous cases, this kind of planning is done without any serious research and understanding of the cultural (or even **environmental**) conditions of the recipient human **groups**. This includes for ex. **values** and **norms**, **beliefs**, traditional ways, etc..., including the deep reasons which explain and, in many cases, justify the former.

Frequently, the results are dreary.

This is a typical systemic problem whose root is the ignorance of deep differences between the mental **frames** of the proposers and the real **stakeholders**.

The main responsibility belongs however to the proposers, who are frequently themselves unaware of the limits of their own **mental frames** of **interpretation**

Such **situation** is a very general recipe for disaster, sometimes even in the long run for the counsellors themselves.

R. RODRIGUEZ ULLOA, who introduces this concept (1994) explains: "This implies that it is the culture of a specific society, as a **whole**, that must be able to accept, as significant and possible, some sequence of **changes** (p. 139)

It becomes indeed ever clearer that many societies reject plans of change, mainly introduced by international **organizations** because they are unable to understand them or to accept the **disruptions** that the projects provoke in their way of living or **Weltanschauung**

→ **CATWOE;Rejection reaction;Soft Systems Methodology**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1251

FEEDBACK¹⁾ – 2)

1) "A unilateral power **amplifier**, with a fraction of the **output** of the **amplifier** subtracted from or added to the **input** of the **amplifier**" (M.D. RUBIN, 1968, p.9).

2) "The use of part of the **output** of a regulated system to compare with the **standard set** for its **program** and produce appropriate **change of input**" (J.Z. YOUNG, 1978, p.292).

The first definition is an engineer's one corresponding to a host of practical devices. It can be generalized by substituting "**effect**" for "**power**".

From this definition it is already obvious that any feedback device will have either positive (increasing) or negative (decreasing) **effects** on the **process**.

J.Z. YOUNG's definition explains what feedbacks do.

He adds that: "**Positive feedback** increases the **input** and negative feedback decreases the **input**", something whose disequilibrating consequences on the system are portentous when sustained feedback of one or the other kind are not adequately compensated.

The Italian epistemologist V. TONINI states: "Feedback is the dominant condition for **self-regulation**, **adaptation** and **automation**; this is sufficient within the limits of a well defined **control** of some **variable**. Feedback is a typically **analogic** and conservative principle. (However) nowadays this certainly very important principle seems insufficient for the **cybernetic regulation** of complex **organisms**" (1971, p.288-9).

What is needed in such cases is a compensating and appropriate alternance of positive and negative feedback, in order to secure **homeostasis**.

The following definition, by G. PASK is more typically cybernetic and, thus, general: "Return of a **signal**, indicating the result of an **action**., in order to determine further **action**" (1961, p.114).

R.L. ACKOFF and F.E. EMERY introduce an **information** as well as psychological connotation in their own definition: "**Information** received by the sender of a **message** about the receipt of, or **response** to his **message**" (1972, p.187).

R. VALLÉE points out that H. SCHMIDT (1894-1968) had already introduced during the thirties an *Allgemeine Regelkreislehre*, i.e. a "General feedback loops science" (1995, p.13), being thus another forgotten precursor of cybernetics.

1252

FEEDBACK and DIRECTIVE CORRELATION²⁾

Feedback, as an elemental behavioral **mechanism**, has been modeled by **cybernetics**.

Repetitive **positive feedback** tends to lead to the system's destruction by **explosion**. Repetitive non-compensated **negative feedback** also tends to its destruction, in this case by progressive immobilization. A good **regulation** needs the alternance of both types, which implies the existence of a **directive correlation**. This last is more than a simple **error control device** in a single **function**, because it must take in account the **transformations** in other **functions**.

1253

FEEDBACK (Anticipatory)¹⁾ – 2)

A feedback "governed by... **response** to the antecedents of **environmental states** that would influence the system unfavorably (or favorably), rather than by **response** to the **state** as actually present" (K. SAYRE, 1976, p.58).

This kind of feedback can work only if paired with a **repertory** of **sequences of events** that have influenced the system formerly. This enables it "... to detect precursors of disruptive **environmental events** before the latter occur and to employ its **effectors** in avoidance procedures" (Ibid). As a result "... corrective **response** precedes **environmental disturbances**" (p.221).

Anyhow, as in any feedback, a **time-lag** is unavoidable.

Moreover, unprecedented **environmental events**, or those whose occurrence remains unpredictable cannot be compensated by anticipatory feedbacks.

Anticipatory feedback of a more complex nature seem to emerge as systems themselves become more complex.

1254

FEEDBACK (Heterotelic)²⁾

"A feedback that works to maintain the **organism** in a certain **relationship** with its operating **environment**, rather than to sustain a certain internal **state**" (K. SAYRE, 1976, p.54).

SAYRE adds: "Heterotelic feedback differs from **homeostasis** in directing the **response** of the environmentally stimulated system back to the **environment** rather than containing it within the system itself" (Ibid).

1255

FEEDBACK (Positive)¹⁾ – 2)

A feedback that accelerates or increases some **process**.

Positive feedback unavoidably is a disequilibrating **phenomenon**.

It implies an accelerated pumping of some specific **resources** from the **environment** by the system, generally feeding a **runaway growth** which finally escapes from any possible **control**.

Such a **situation** leads normally and swiftly towards the exhaust of the critical **resource** and, consequently to the **collapse**, or even destruction of the system.

One may give as examples: a nuclear or chemical explosion; the inordinate **growth** of a **population**; a **runaway** bull or bear market (mind the 1929 and 1987 crashes); a fire; a cancer.

Fortunately, but possibly somewhat optimistically in some cases, in J.H. MILSUM's words: "Upper and lower **constraints** always exist in real systems which prevent true **runaway**" (1968, p.39). A good **knowledge** of these **constraints**, – in many cases located in the **meta-system** – and their proper use, is very useful in maintaining the **stability** of a system. On the contrary, unawareness of their existence may lead to their unwitting removal, **triggering** the **runaway process**.

For practical purposes, feedbacks, natural or introduced, specially positive ones, should always be closely monitored, in order to avoid unforeseen and unwanted quantitative **effects**, leading ultimately to qualitative ones.

Positive feedbacks can be controlled, but only a priori, by well conceived **design**, not a posteriori.

1256

FEEDBACK (Positive and Negative)¹⁾ – 2)

There is some redundancy in feedback terminology.

According to J.H. MILSUM "... the following approximate equivalence exist between ... various expressions (in use):

"Positive feedback, or Positively- connected loop equals: **Deviation-amplifying Mutual Causal Loop** (MARUYAMA), Disequilibrating Feedback (BOULDING).

"Negative feedback or Negatively-connected loop equals: Deviation-counteracting (or Attenuating) Mutual Causal Loop (MARUYAMA); Equilibrating Feedback (BOULDING)" (1968, p.23).

J.de ROSNAY describes the different types of feedbacks in this way:

"In any feedback (as its name shows), **informations** about the results of some **transformation** or **action** are sent back at the entry of the system, as **data**. If these new **data** tend to make easier or accelerate the **transformation** in the same direction as the former results, we have a positive feedback: its **effects** are cumulative. On the contrary, if these new **data** acts in the direction opposite to the former results, we have a negative feedback: its effects stabilize the system. In the first case, there is an exponential **growth** or decrease; in the second one, **equilibrium** is maintained.

see figure next page

Positive feedback..... Negative feedback
Divergences increase There is **convergence**
 towards a **goal**

J.de ROSNAY insists on the destructive effects of positive feedbacks:

"A positive feedback leads to a divergent behavior: illimited expansion, explosion (**runaway** to infinity) or complete block up of **activities** (**runaway** towards zero), as "more" engenders "more", with a "snowball effect". There are numerous examples: chain reaction, demographic **growth**, **growth** of a business, capital with compound interests, inflation, cancerous cells proliferation.

"On the contrary when "less" engenders "less", everything is shrinking. Some typical examples are default of a business or economic depression" (As shown by J.M. KEYNES).

"In either case a positive feedback left free can only lead to destruction of the system, be it by **explosion**, be it by blockage of all its **functions**. The exuberance of positive feedback – this potential death – must be controlled by negative feedbacks.

"This is the essential condition if a system is to maintain itself through **time**.

"A negative feedback leads to an adaptive or finalized **behavior**, i.e. **converging** towards an **objective**: maintaining a **level**, a temperature, a concentration, a velocity, a course.

"In some cases, the **goal** became established by itself and has been maintained all along **evolution**: the system "secreted" its own finality (a steady composition of atmosphere or oceans in the **ecosystem**; of the **level** of glucose in blood, etc.). In other cases it has been set by man into **machines**: **automata** and **servomechanisms**.

"In a negative feedback, any positive variation evokes a negative one (and conversely). There is a **regulation**: the system oscillates around an **equilibrium** position which it may never reach: a thermostat or a water tank equipped with a float are very simple examples of **regulation** by negative feedback" (1975, p.102-3).

The notions of positive or negative feedbacks carry some quite widespread **ambiguities**:

1- Those not familiar with the question tend to associate "positive" with "good" and "favorable" and negative with the contrary. While it is not exactly the opposite way, it is correct that positive feedbacks are generally destructive when repeated, while negative feedbacks (as understood by de ROSNAY) (see below) have regulating and equilibrating **effects**.

2- Some understand as "negative feedback", the "less" brings about "the less" described by de ROSNAY, as one of two opposite kinds of positive feedback. In this case, the negative feedback of de ROSNAY could be described as "compensated feedback" or "**regulator**": an alternance of accelerating and braking effects. There is no rigid **convergence** towards some **goal**, but the maintenance of **dynamic stability** (or **homeostasis**) within a maximal and a minimal **value**.

back through which the system adapts itself, according to the existing regulating **mechanisms** that it already possesses, which become activated, as they are.

However, the system may need to modify the **regulators** themselves in order to better their **action**, as needed when its **responses**, based on the **regulators**, as they are, become unsatisfactory. This **process** is basic for **learning**.

W.R. ASHBY explains it in the following way:

"The basic **rule** is equivalent to the following formulation:

"1 – When the essential **variables** (of the system S) are not all within their normal **limits** (i.e. when the trial has failed), no **state** of S is to be equilibrated, for the **rule** is that S must go to some other **state**.

"2 – When the essential **variables** are all within normal **limits** then every **state** of S is to be equilibrated" (1960, p.84). (ASHBY's first point is interestingly close to H. SELYE's concept of "**General Adaptation Syndrome**", but is obviously more general).

ASHBY pursues: "... any system that has essential **variables** with given **limits**, and that adapts by the **process** of testing various **behaviors** by how each affects ultimately the essential **variables**, must have a second feedback formally identical (**isomorphic**) with that described. This deduction holds equally for **brains**, living or mechanical" (p.85).

1257

FEEDBACK (Second order or double)^{1) - 2)}

A feedback which modifies any primary feedback, thus changing the former **response** of a **regulator** to some **class** of **inputs**.

When a system's **parameter** undergoes a variation, the first **reaction** of the system is processing the **information** it receives about the **change**. This generally leads to a first feed-

1258

FEEDBACK (Self-normative)¹⁾

A **learning process** by which the trainee corrects and restricts its or his/her **repertory** of **actions** by **perception** of its or his/her own **performance**.

A bird who is learning to sing "must be able to hear itself during the motor development **phase** (**period** during which it produces a "pre-song"). If it is deprived of hearing before the

Figure: see entry **FEEDBACK (Positive and Negative)**

From J. de ROSNAY: 1975, p. 102

beginning of the "pre-song", it cannot harmonize its vocal production with what it recorded of its species one. It can then produce only a variable song, unstructured and devoid of all the characteristics proper of its species" (J.W. CLARK, 1972, p.468).

This seems to be a very general feature of **learning**, as shown for example by the inability of the "wolf-children" to learn correctly a human **language** when isolated from humans for too long a **period**. It seems also to be related to the concept of **constraint** (ASHBY): any **learning** is at least in some respects a constraining **algorithmization** of potentially much more extended capabilities.

1259

FEEDBACK (Unforeseen)^{1) - 4)}

In many **complex systems** – particularly natural systems manipulated by man – unforeseen feedbacks appear after some **time**.

Most human interventions in natural systems take place without a satisfactory **understanding** of the intricacies of the same. There is an implicit belief that some supposedly isolated **interaction** can be modified without serious **side effects**. Such a belief is a consequence of the hitherto dominant **paradigm** of **lineal sequential determinism**.

Many human made disasters are results from such unforeseen feedbacks (C. FRANÇOIS, 1989). Some examples are acquired resistance of insects and pathogens to insecticides and synthetic drugs, negative results of irrigation schemes, economic measures fuelling inflation, etc...

One of the most dangerous aspects of this problem is that unforeseen consequences emerge only with a **time lag**, sometimes a very long one. Moreover, they may diffuse in unsuspected ways to many **parts** of the system. As a consequence, they can be quite difficult to control when they surface, specially when their true nature is still not yet clearly understood.

1260

FEEDFORWARD^{1) - 2)}

"**Information** that attempts to predict **disturbances** before they actually affect the system" (Adapted from M.C. JACKSON, 1992, p.99).

Information about past **events** can in many cases be ordered and used to **forecast** possible future **events**. Such a **knowledge** can then be used to try to correct the course of these forecasted **events**. The concept is fuzzily transferred from engineering.

M.D. RUBIN describes technical feedforward devices in the following terms: "Feedforward occurs when a part of the **input signal** is also fed around the **amplifier** and is in some way

combined with the **output** of the **amplifier** for further processing, in such a way that the **output signal** is *not* recirculated through the **amplifier**" (1968, p.18).

This is thus some kind of **buffer** device, used to damp possible wild **fluctuations**. "Forward" seems to imply the **intention** to **control** these **fluctuations**, whose possibility is foreseen.

negative-feedback amplifier with feed-forward.

1261

FEIGENBAUM's NUMBER^{2) - 5)}

FEIGENBAUM's number is related to **period-doubling sequences** in systems turning **chaotic** through the increase of **parameter a** in the difference equation $x_{n+1} = ax_n(1-x_n)$, which can also be written in its quadratic form $x_{n+1} = ax_n - ax_n^2$, where the second term is **nonlinear**.

R.V. JENSEN states: "As *a* is increased, the **long-time** motion converges to period – 8, – 16, – 32, – 64... **cycles**, finally accumulating to a **cycle** of infinite **period** for $a = a_{inf} \approx 3.57...$ FEIGENBAUM was able to prove, using a remarkable application of the **renormalization group**, that the intervals over which a **cycle** is stable decrease at a geometric **rate** of ~ 4.6692016 . The tremendous significance of this work is that this **rate** and other properties of the **period-doubling bifurcation sequence** are universal in the sense that they appear in the **dynamics** of any system which can be approximately modeled by a **nonlinear map** with a quadratic extremum. FEIGENBAUM's theory has subsequently been confirmed in a wide variety of physical systems such as turbulent fluids, oscillating chemical reactions, **nonlinear electric circuits**, and ring lasers" (1987, p.171).

It would be very interesting to see if this property conducive to the onset of **chaos** is also present in ecological, economic and **social systems**.

1262

FENETECISM²⁾

A general **taxonomy** of **living systems** based on their readily observable characteristics.

Feneticism recommends the use of the maximum number of known characteristics, but does not use any ponderation of the same. It tries only to **cluster** the species which present more common characteristics.

→ "**Cladistic analysis**".

1263

FIBONACCI SERIES^{2) - 4) - 5)}

An additive series of consecutive numbers whose ratios develop in the following way

This series was introduced by the Italian mathematician FIBONACCI in 1220.

As can be observed, every successive term of the progression 1, 1, 2, 3, 5, 8, 13, etc.,... is the sum of the two former ones.

On the other hand, the limit of the ratio's sequence is $(\sqrt{5}+1)/2 = 1.618...$, the so-called **golden section**.

Both the series and the **golden section** appear in numerous natural **structures** and seem to reflect opposite **constraints** in **field dynamics**. It thus reflects and explains the genesis of specific **forms**, as already shown for example by SCHIMPER, BRAUN and BRAVAIS for plants, in the 19th Century. It is also implicit in d'Arcy W. THOMPSON's "Growth and Form" (1916).

Its use in systemic **modelling** could probably be much developed. A.A DAVYDOV published in 1992 a very stimulating paper on this subject: "Theory of Harmony of Proportions and **Functions** in **Social Systems**" (1992).

1264

FIELD²⁾

A region of **space** endowed with a vectorial property corresponding to some specific **action**, f. ex. electrical, magnetic or gravitational.

This **concept** and **model**, elaborated by FARADAY and MAXWELL, replaced the **model** of a void **space** in which particles, charges or bodies attract or repel themselves through an instantaneous **effect**.

K.DE GREENE generally characterizes fields as follows:

" – All **matter** is inherently **unstable** and can be observed to **decay**.

" – A field in itself is continually fluctuating.

" – A field can cause an initially **homogeneous** system to develop new **spatiotemporal structure** (e.g. **dissipative structures**); the original system can become **unstable** everywhere in the face of infinitesimal **fluctuations**.

" – A single underlying force can, accordingly to the perspective of the **observer**, be manifested in apparently very different forms like the electromagnetic, weak and strong forces and perhaps eventually the gravitational force (to result in a grand **unified field theory**).

" – Attraction and repulsion are fundamental properties of forces.

" – There may be primary and residual forces.

“ – Forces have characteristic spatial **ranges** and strengths which may be very limited or immense.

“ – The basic constituents of **matter** interact via forces; a force binds **matter** together.

“ – Particles convey forces; a field emanates from a particle and extends over some volume of **space**” (1994, p.11).

Remains to be seen how the concomitant concepts of **space** and force, not to speak of **energy** and **time** could be defined or described in a not too circular way.

Various fields may interact in a complex way. As a result, a field can be **turbulent**.

In the concept of field, any **element** creates its own field, whose strength decreases with distance: a field implies a **gradient**. This idea can be extended to systems influence on their **environment**.

1265

FIELD AS A REPRESENTATION ²⁾

In a representation of a field- for ex. a static descriptive figure - “...the only real meaning of the lines is to represent the possible **paths** along which a third charged body would move (depending on its charge) if it were placed otherwise unhindered in the field”(J. Bryant, 1991, p. 3)

However, in the **Chladni** experiment with deposition of iron filings on glass surface placed above a magnetic field, the filings do not move anymore and the field is in some sense statically materialized in its **effect**.

1266

FIELD (Global) ²⁾

A combination of all local **variables** (J. THIERIE, 1990, p.442).

The Global Field is reflected by general **constraints** which affect the system as a **whole**.

J. THIERIE writes: “With regard to a system governed by a definite global kinetic **evolution** law (**coherence**), we are searching for... the consequences of introducing discernibility of **parts**, at the **level** of local evolution laws (**partitions** method).

“...the local **steady states** of such **partitions**, when kinetics is **nonlinear**, are not only fixed by the global **variable** and the kinetic values of **parameters** (as usual) but also by a combination of all local **variables**, called *global field*.

“This special **situation** leads to the possibility for local **bifurcations** to occur without risk for the global **stability**”.

“... those systems offer the unexpected property of deeply rehandling the **frequencies distributions** of the local **variables**, keeping a global **invariant** and **coherent behaviour**” (1990, p. 442).

This looks as yet another reformulation of **organizational closure**. Besides, it could probably be connected to **chaotic attractors** mathematics, which allows for local **randomness** within a global **determinism**. One may consider as an example the large physical and psychological **autonomy** of the living being, once the **constraints** of its basic biology are respected.

1267

FIELD of a system ²⁾

“The **phase-space** containing all the **lines of behavior** found by releasing the system from all possible initial **states** in a particular **set** of surrounding conditions” (W.R. ASHBY, 1960, p.28).

ASHBY states: “The concept of “field”... defines the characteristic **behavior** of the system, replacing the vague concept of what a system “does” or how it “behaves” (often describable only in words) by the precise **construct** of a “field” (Ibid).

It is however debatable whether it is always possible to obtain a full **knowledge** of “all possible **states**”, let alone of the full **phase-space**.

Nevertheless, ASHBY offered very interesting insights into the concept of field in his “Introduction to Cybernetics” (chap.9 “Incessant **transmission**”, where he describes the **set** of all the possible **transitions** of a system by **matrices**) (1956).

1268

FIELD (Social) ⁴⁾

“An **autonomous** microcosm within the social macrocosm”(P. BOURDIEU, 2000)

“Autonomous” is a perfect characterization of such a microcosm, as it means that it possesses (i.e. establishes and maintains) its own definitory **norms** and **rules**.

Social fields can be observed in all human institutions and **organizations**- as for ex. in religious **groups** of any kind, in business, in politics, in the arts and even in scientific disciplines within academic **structures**.

It is not proper to any **culture**, but it offers a wide arc of specific forms in accordance with environmental and historical conditions.

Recent research rises the possibility that some **precursor forms** of social fields may exist in some insect societies, as beehives and termites mounds.

Social fields could conceivably be related to **competition** for the occupation of the internal social **space**, and also to some kinds of age classes or **cohorts**.

1269

FIELD (Stability of a) ²⁾

According to W.R. ASHBY: “A field will be said to be stable if the whole **region** it fills is stable; the system that provides the field can then be called stable” (1960, p.49).

1270

FIELD: The Relativistic concept ³⁾

M. MARNEY and P.F. SCHMIDT write: “...EINSTEIN succeeded in formulating the fundamental equations of an analytical mechanics in which the previously intractable **distinction** between gravitational and electromagnetic forces no longer figured. In this novel conceptual format, the distinct **categories** of **space**, **time**, **matter** and **energy** were withdrawn and replaced by multiple **components** of a single formal **entity**: a unitary field characterized by a metrical geometry of the Riemannian type” (1976, p.189).

This is the reason why, in this dictionary, these four basic conceptual **categories** are co-defined in a tautological way.

1271

FIELD THEORY (Unified) ^{1) - 3)}

K.DE GREENE has proposed the following structure for a “Unified field theory”, giving for each contributing theory the main **constructs**.

“-Field theory in particle physics

Field

Force

Only totally meaningful

System-environment interaction

Attraction and repulsion

Inherent **instability**

“-Field theory of **critical phenomena**

Critical point

Correlation of elements

Trigger-and-ripple effect

Phase transition

Order parameter

Collective behavior

“-Chaos theory

Deterministic disorder

Inherent **unpredictability**

Source of new information

“-Synergetics

Micro-macro interaction

Spontaneous behavior

Order parameter (Extended)

Stochastic/deterministic behavior

Nonequilibrium phase transitions

Critical behaviors

“-Catastrophe theory

Catastrophe discontinuities

Exogenous forces (**Control parameters**)

Deterministic behavior

Equilibrium focus

Multistability

Hysteresis path

"-Dissipative structure theory

Thermodynamically open systems

Driving role of fluctuations

Stochastic/deterministic behavior

Nonequilibrium/far-from-equilibrium focus

Self-organization

Structural change

"-System dynamics

Informationally closed system

Feedback loop structure

Endogenous behavior generation

Deterministic behavior

Equilibrium/desequilibrium focus" (1994, p.18).

This quite complete synthesis emphasizes the **convergence** of a number of independently emerged theories and concepts within the general **frame of reference** of cybernetics and systemics and the corresponding **methodologies**.

Many interesting **linkages propositions** could be proposed and fruitfully explored

In a different spirit, the French biologist H. PRAT did propose a theory of the "Unitary field" in biology (1964).

1272

FIELD-FUNCTION ²⁾

"A **knowledge-set** which expresses the **relationship** between the **exogenous** factors present in the system's **environment** and the properties of the system's **parts**" (J.W. SUTHERLAND, 1974, p.37).

This concept, thus somewhat fuzzily defined, expresses that it is not possible to understand and explain the system without reference to its **environment**.

It seems however very difficult to establish precisely such a **knowledge-set**. Until now we do not have any very reliable method for tracking all the **elements** and **interconnexions** that should be integrated in such a field-function. This is, for example, a patent weakness of FORRESTER's **Systems Dynamics**, underlined by the controversial character of the famed **CLUB of ROME** studies.

1273

FIELDS (Interactions between) ²⁾

F. ROBB writes: "In general any **nonequilibrium distribution of matter/energy** can be described as a **flow field** embedded in a larger **flow field** with which it interacts. Where the two fields interact and the field forces are mild, no new properties emerge and the **processes** tend to **homogeneous equilibrium**. Where the field forces are strong, when the **gradient** is steep relative to the diffusion potential of the uncorrelated **interactions** of the **components** at the **interface**, then, subject to the **constraints** in the field, **emergent** evolutionary **behavior** is observed" (1990, p.390-91).

He adds, quoting R. SWENSON: "... in coherent fields, the **emergence** of **structure** is the most probable, indeed the inexorable, outcome of **change** in **time**. **Structure** building is the preferred route to **equilibrium** in what SWENSON calls an "incommensurable" universe. It is preferred because it is the fastest, the most efficient, way to maximize **entropy production**" (Ibid).

The connexion with PRIGOGINE's **thermodynamics of open systems faraway from equilibrium** is obvious.

Very similar ideas were also exposed under the guise of a theory of **vortexes** (or whirlpools) by the French engineer Ch. LAVILLE as early as 1950.

1274

FIELDS within FIELDS within FIELDS ^{1) - 2)}

This curious expression was the name of a journal published in the seventies by J. STULMAN. It has been again used by K.DE GREENE (1991, p.65) in his studies on the interconnections between short, medium and long **cycles**.

The **concept** has not been completely explored. It seems however to have the general **meaning of a hierarchy of action levels**.

Small and local **effects** are produced by small and local fields, which are numerous. They are however framed in spatially and temporally more extended fields, which in turn are still framed in ... and so on. An example is the variations of temperature under the dependence of various astronomical fields influences, themselves hierarchically ordered, from daily to seasonal, to sun activity, to secular and multi-millennium **cycles**, and even possibly galactic **effects** on the scale of geological ages.

The resulting general conceptual **frame** could be more or less formalized through **renormalization models**, i.e. with a degree of **self-similarity** through levels. (See "Self-similarity in WEIERSTRASS functions").

However, the use of such **models** for **forecasting** is problematic, as it must be applied to very **complex chaotic systems** (even if they remain somehow **deterministic** in a limited sense).

1275

FIGHT OR FLIGHT RESPONSE ⁴⁾⁵⁾

A behavioral response elicited mainly by the reaction of the limbic **level** of the **brain** when the individual is challenged by some external aggression.

The French biologist H. LABORIT developed a comprehensive study of the subject, under the generic term "Agressology", whose roots are biological and physiological (1970, 1976).

→ **Brain; Imprinting; Stress**

1276

FIGURE-GROUND ^{3) - 5)}

"The characteristically unequal emphasis in human visual **perception** on a figure, which stands out against an undifferentiated **background**, which merely contributes to that **perception**" (K. KRIPPENDORFF, 1986, p.30).

This is a basic condition in **Gestalt theory of perception**. It has been used by many artists, as for example M.C. ESCHER, to create optical illusions.

The concept is not merely limited to visual **perception**. KRIPPENDORFF observes that the same "...unequal emphasis is found in the **distinction** between a word and its **context**, between an **organism** and its **environment** or between **pattern** and **chance**" (Ibid).

He also states that "... visual examples of figure and ground reversals... are the equivalent of paradoxes" (p.31). **Double-bind** statements illustrates the same point in logics.

From a systemic viewpoint it is significant of the usefulness of **subsystems** good identification, and of making clear the difference between the system and its **environment**.

Janet McIntyre suggests that "when communicating in the caring professions we need to be constantly aware of this figure/ground nexus.

The **analogy** can help us to understand that the **perception** of the same **situation** can differ, depending on what you are concentrating on" (1988, p. 113)

Using the figure-ground as an illustrating **metaphor** can be quite helpful in psychological and psychiatric **situations**, as the "patient"-does not live isolated from his/her **environment**.

Even conflictive **socio-cultural issues** could be usefully looked at in this way.

In her paper McIntyre also draws analogies with other multi-facets **models**, as Mc LUHAN and POWERS tetrad and DE BONO six thinking hats (1989)

see figures next page

→ **Embedment**

1277

FILTER ^{2) - 3)}

Any device that selects **inputs** in a system.

No system could ever cope with the totality of the potential **stimuli** it could receive from the global **environment**: its "fuses" would immediately "blow out". Its **functional** characteristics depend precisely on the more specific **environment** whose **inputs** are significant for it.

Any system is however shaped from its genesis by a **set of rules** that will first define with precision what is acceptable for it and next, in a progressive way establish which **classes** of **inputs** it will finally accept, within the **range** of the acceptable ones.

Figure: see entry **FIGURE-GROUND**

Figure-Ground
An engraving by M. ESCHER

Figure-Ground: The well-known "Old-lady", "Young-lady", teaser

This **process of constraint** requires and produces the construction of the selective devices called filters.

Filters can be adaptive to different **values of stimuli**: it is for example the case of the eye's pupil, which may contract or expand within an acceptability **range**, according to the intensity of light.

Any **communication** which is not merely a blind **interaction** is based on filters (or **constraints**) that define a **language** of shared meanings (K. BERRIEN, 1968, p.113).

1278

FILTRATION^{1) - 2)}

"The **selection** of a **subset** for **transmission** to a **receiver**, from the **set** of **messages** intended for him" (R. ACKOFF & F.E. EMERY, 1972, p.191).

ACKOFF and EMERY add: "An intermediary may filter **messages** with the intention of better serving the **receiver's purpose**, as in transmitting only **messages** that he believes are of value to the **receiver**. Or the intermediary may filter for its own or another party's **purposes**. When it does so, it engages in censorship" (ibid).

In fact, the concept of filtration is much more general than this. Any **complex system** is pre-conditioned to admit only useful **inputs** from its **environment** and use numerous filtration devices to protect itself.

From a different viewpoint, as observed by D. DUBOIS, any **modelization** implies selectively filtering out properties of the **concrete system**.

"Any **model** is constructed by reference to a particular **scale** of the system, without taking in account the details on the lesser **levels**. Only *some* properties of these lesser **levels** are considered" (1990, p.75).

→ **Structural differential**

1279

FINALITY^{3) - 4)}

Goal or **objective** that a system *seems* to pursue, in spite of **disturbances**, induced by its **environment** or of **endogenous** origin.

In systemics this concept does not imply intentionality. It merely characterizes an observed **behavioral pattern**, which appears to be recurrent or permanent. It is thus neither **mechanicist**, nor transcendental.

Finality, in this systemic-cybernetic meaning, is characterized by **regulation** around definite **standards**.

Intentional **behavior** seems proper only to **human systems**, as claimed for example by J.L. LEMOIGNE, who speaks of "self-finalization" as human capacity to define own **goals**. This could possibly be extended in a limited sense to superior animals.

As observed by E. SCHWARZ, in no case does **teleonomy** - a notion more immune to conceptual distortions - imply some **cause** in the future for the present **state**. (1993, p.6) Thus any science fiction **time paradox** is avoided.

In a different way, the French biologist J. MONOD considered that the complex organization of the human **brain** entails a kind of predictive capacity and accordingly, some measure of **control** for the future of its owner. If alternative possibilities exist, then **decision making** makes sense, as well as **goal-directness**, **goal-seeking** (and **purpose**)

→ **Teleonics; Teleonomy; Teles**

1280

FITNESS¹⁾²⁾⁵⁾

Selective **value** of some characteristics of a system, a member of a species or a species as a **whole**.

Of course fitness is a relative concept. It cannot be understood without some specific **environment**, as for example ecological or enonomic.

However its meaning is quite general. It applies not only to individuals, but also to **populations**. As conditions change, the transient nature of fitness becomes obvious, be it for dinosaurs at the end of mesozoic, or horse driven coaches at the beginning of the 20th Century.

Fitness is now researched experimentally through "**evolutionary robotics**" (D. FLOREANO, 1996 and 2002 and M. SIPPER & J.A. REGGIA, 2001)

Floreano "computers **robots**" (i.e. electronic **models** of robots) and their **behavior** is discussed extensively in a "written symposium" ("Symposium écrit") on "**artificial evolution**", organized by the Institut de la Méthode (Lausanne University, Switzerland)

→ **Evolution (artificial), Paralled distributed processing, Robot (Khepera), Weights (Synaptic)**

1281

FITNESS CRITERIA^{1) - 3)}

There are no **absolute** fitness criteria. All criteria are related to some characteristics, deemed positive or negative, according to specific **aims**, but possibly insubstantial or irrelevant from another **viewpoint**.

As an example, A. JACQUARD observes: "The very expression "improvement of species" is perfectly illusory. We did not *improve* wheat, nor cows, nor horses. We have improved wheat's capacity to use some fertilizers (note: in some regions), cows capacity to produce milk (note: under specific conditions), horses capacity to run fast (note: mainly on race tracks)... But may we really boast about having improved maize or horses, while we have rendered them unable to survive without us?" (1978, p.162).

As to fitness as a **criterion** of "survival of the fittest", it does not amount much more than the tautological "survival of the survivors", the survivors being declared the fittest... because they survived.

1282

FITNESS FUNCTION²⁾⁵⁾

The criteria by which **sets** of **rules** can be selected to create an evolutionary **process** aimed at evolving a **self-replicating automaton**.

M. SIPPER and J.A. REGGIA (2001) devised a "fitness function composed of a **weighted** sum of three measures: a **growth** measure (the extend to which each **component** type generates an increasing supply of that component), a relative **position** measure (the extend to which neighboring components stay together) and a replicant measure (a function of the number of the actual replicatory **elements** present)

With the right fitness function, **evolution** can turn rule sets that are sterile into ones that are fecund; the **process** usually takes 150 or so generations".

"The ability to replicate without a **self-description** may be relevant to questions about how the earliest biological **replicators** originated. In a sense, researchers are seeing a continuum between non-living and living **structures**" (p. 31-35)

→ **Artificial life; Cybernetics (2nd); Evolution (Artificial); Game of life (Conway); Neural network; Paralled distributed processing; Weights (Synaptic)**

1283

FITNESS in REPRESENTATION^{1) - 3)}

According to von GLASERSFELD: "The substitution of the concept of fit (and its dynamic corollary, *viability*) for the traditional concept of *truth* as a matching, **isomorphic**, or **iconic representation** of *reality*, is the central feature of the theory of **knowledge** I have called **Radical Constructivism**" (1988, p.77-8).

The quest for fitness is the **activity** of **observers**, who postulate the existence of reality but also recognize that is cannot be fully transparent to them.

Of course, fitness in **representation** thus becomes unavoidably **empirical**, pragmatic, relativistic and contingent.

A similar concept was developed by the Swiss epistemologist F. GONSETH ("Idonéité") (1945).

1284

FITNESS: rigid, adaptive, evolutive or what?^{1) - 3)}

The concept of fitness of the **organization** or **behavior** of systems has been discussed by various authors.

B. BANATHY for example advocates the necessity of a good fit for any project, while G. BROEKSTRA writes "... the rationality of **equilibrium** became associated with the order-through-fit principle. It was understood that **fluctuations** in the form of misfits, inconsistencies, paradoxes, or contradictions, had to be damped or suppressed. In this way, the fit **paradigm** became a unitary approach driving an **organization** toward a particular **stable attractor state (configuration)**" (1992, p.1025).

Within this **frame** the **concept** of fitness can carry two different **meanings**:

- the first one, strong and even absolute, does not admit any "**deviation**". This is the hallmark of authoritarian bureaucracy and it sometimes ends with the destruction of the system.

- The second one, weaker and more realist, admits some **fluctuations** in order to maintain **dynamic stability** within more or less narrow **limits**. This is the adaptive approach.

BROEKSTRA goes further and writes: "However, although a tight fit may lead temporarily to excellence... in the long run fit may lead to failure. Therefore a new way of thinking about organizing is called for, one that encompasses this paradox. The old fit perspective does not disappear, but is absorbed in a more comprehensive theory...

... the **non-equilibrium**, evolutionary **paradigm** of **self organization** as represented by **chaos** systems theory, and in particular PRIGOGINE's theory of **dissipative structures**, in short, the **Chaos** hypothesis, constitutes a powerful **change of language**..." (Ibid.).

While individual systems may survive long time only by adapting, collective systems as species or **organizations** do survive in the long run only if they *evolve*.

Fitness becomes than an ever provisional result of the capacity to construct working higher **complexity** and restaure **dynamic stability** when, after wild **fluctuations** due to massive **inputs** (of **energy** or **information**) coming from a changing **environment**, the system undergoes **dissipative structuration**, **bifurcations** and an **emergence process**.

This leads to the **chaos** and **criticality** viewpoint, thus stated by St. KAUFFMAN, (quoted by R. RUTHEN): "It turns out that in a wide variety of coupled systems the highest mean fitness is at the **phase transition** between **order** and **chaos**... The bold hypothesis is that complex **adaptive systems** adapt to, and on the edge of **chaos**... It now begins to appear that systems in the complex **regime** can carry out and coordinate the most complex **behavior**, can adapt most readily and can build the most useful **models** of their **environment**" (1993, p.117).

It finally seems that fitness is quite elusive and ever changing, confirming BROEKSTRA's **understanding** and BANATHY's concept of **co-participative** and necessarily permanent **design**.

→ **Equilibrium (Punctuated)**

1285

FITNESS VALUE⁵⁾

A measure of the more or less satisfactory correspondence of a problem solution with some stated **goal**. (adapted from P. DENNING, 1992a, p.12).

This concept is referred to the use of **genetic search algorithms**, by which trial solutions are cross-bred, allowing "only the *fittest* solutions (those accorded the highest **values**) to survive after several generations" (Ibid).

In this way "biological **analogies** in computing and **information analogies** in biology" are explored (Ibid).

1286

FIX (Quick)¹⁾

Any local or specific **adjustment** which does not take into account the systemic nature of the **problem** it aims to solve.

Quick fixes frequently suppress some terminal **effect** of a global maladjustment. In many cases, the ill **effect** reappears after some time, or propagates in a different way to another **part** of the system. The tendency to quick fixes is widespread in front of social and economic trouble as well as in case of **machine** or **man-machine** maladjustment, and even sometimes in medicine.

It should be replaced by more thoughtful **methods**, based on a better **understanding** of the – sometimes hidden – complex **interactions** within the system.

1287

FIXED POINT²⁾

The terminal point of a **trajectory** in the **state space** of a system (J. CRUTCHFIELD et al, 1989, p.41).

CRUTCHFIELD et al explain: "... this fixed point is an **attractor**... Any system that comes to rest with the passage of **time** can be characterized by a fixed point in **state space**. This is an example of a very general **phenomenon**, where losses due to friction or viscosity, for example, cause orbits to be attracted to a smaller **region** of the **state space** with lower dimension" (Ibid).

In fact, the fixed point is generally the **final state** of the system, when it undergoes no more **transformations** (as for example a physical system, like the pendulum) or is not anymore a system (as in the case of **living systems**). Such a final fixed point is also sometimes called a **sink**. However, this word also

has another quite different **meaning**. A fixed point which attract in one direction and repels in another is called a **saddle**. A point of origin is a **source**.

1288

FLEXIBILITY^{1) – 4)}

1. "Capacity of an **organization** to suffer limited change without severe disorganization" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.41).

2. Capacity of a system to adapt itself to strong **perturbations** by **switching** from one **domain** of **dynamic stability** to another (Adapted from C. HOLLING – 1976).

In another definition K. SAYRE emphasizes the relation between the system and its **environment**. He also uses the somewhat controverted concept of **negentropy**: "... the capacity of an **organism** to establish efficient couplings with its **environment**, under a range of different conditions, through which **negentropy** can be obtained to support its **growth** and **metabolism** and to control its **response** to **environmental** conditions" (1976, p.117).

This concept is akin to W.R. ASHBY's **Law of Requisite Variety**. Flexibility also seems to be a condition for better **adaptation**, and probably **evolution**.

SAYRE quotes J. HERRICK, who wrote: "Progressive organic **evolution** may be defined as **change** in the direction of increase in the **range** and **variety** of **adjustments** of the **organism** to its **environment**... This involves increase in the **complexity** of **structure**, ensuring **sensitivity** to a greater **variety** of **environmental energies** and more refined sensory analysis" (1946, p.469).

Thus, increased flexibility, through "increase in the **complexity** of **structure**" is also related to **dissipation** of **energy** and this early insight has been later vindicated by Prigoginian **dissipative structuration** in systems **far away from thermodynamic equilibrium**.

Another definition given by H. VOLBERDA and T. DE LEEUW applies somewhat more restrictively to human **organizations**: "... the degree to which an **organization** possesses a **variety** of actual and potential procedures, and the rapidity by which it can implement these procedures, in order to increase the **control** capability of the **management** and improve the controllability of the **organization** and the **environment**" (1992, p.1083).

According to G. BATESON: "Flexibility may be defined as uncommitted potentiality for **change**" (1973, p.473).

The most stable systems (or **organizations**) are *not the most rigid ones*, but those which can oscillate with some **amplitude** within the **limits** of their conditions of **dynamic stability**.

FEIBLEMAN and FRIEND give the following example: "A river is a flexible **organization** (i.e. system) since its course and dimensions may be altered to a very great extent without damage to its essential **structure**" (Ibid).

Flexibility is maxima in very decentralized and **heterogeneous** systems. However, an excess of flexibility may lead to loss of **cohesion**, incoherence and break up of the system.

In R.L. ACKOFF's opinion however: "There is no limit to the amount of flexibility that can be designed into a system. The more uncertainty an **organization** faces, the more flexibility should be designed into it" (1988, p.245).

And: "The more flexible an **organization** is, the more it can redesign itself... Therefore, the ability to learn and adapt rapidly and effectively must be designed into **organizations** intended to be flexible" (Ibid.).

→ **Autonomy, Resilience**

1289

FLEXIBILITY (Distributed)^{1) – 2)}

As stated by W.R. ASHBY and, later on by G. BATESON (1973, p.474): "The **distribution** of flexibility among the many **variables** of a system is a matter of very great importance".

This is a logical consequence of the character of **complex systems** of being interconnected **networks**, which allows, to a point, for redirected compensation of local **perturbations**.

H. SELYE's **General Adaptation Syndrome** reflects the same fact, and so does the reconstruction of cerebral **networks** which may sometimes take place after a cerebral haemorrhage.

Distributed flexibility seems to be a very basic property of all social systems, even those which are strongly integrated.

1290

FLEXIBILITY (Loss of)¹⁾

Loss of flexibility in a system is a pathology.

G. BATESON explains it in the following way: "When under **stress**, a **variable** must take a value close to its upper or lower **limit of tolerance**, we shall say ... that the system is 'up tight' in respect to this **variable**, or lacks flexibility in this respect.

"But, because the **variables** are interlinked, to be up tight in respect to one **variable** commonly means that other **variables** cannot be changed without pushing the up-tight **variable**. The loss of flexibility thus spreads through the system. In extreme cases, the system will only accept those changes which change the **tolerance limits** for the up-tight **variable**". This is related to SELYE's **General Adaptation Syndrome**.

If flexibility is totally lost, the system will eventually break up.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Flexibility must be exercised unless it may be lost. In BATESON's words: "...if a given **variable** remains too long at some middle **value**, other **variables** will encroach upon its **freedom**, narrowing the **tolerance limits** until its freedom to move is zero or, more precisely, until any future movement can only be achieved at the price of disturbing the encroaching **variables**" (1973, p.479).

This is particularly obvious in biological systems, but could seemingly be applied in mental, psychological and social ones.

1291

FLEXIBILITY of a MODEL ¹⁾ - 5)

The possibility of applying the same model (with slight modifications if needed) to a number of different kinds of **situations** or systems.

This can be understood in various ways:

- The possibility to apply the model to different **levels of complexity**. A good example is the general model of **living systems** elaborated by J.G. MILLER (1978).
- The possibility to apply it to different kinds of systems hypothetically endowed with some common properties. A good example is M. EIGEN's **hypercycle** model (1979).

1292

FLICKER NOISE ¹⁾ - 2)

An irregular **criticality signal** corresponding to the triggering of a timely **variety** of sudden **changes** in unstable **composite systems**.

P. BAK and K. CHEN state: "...flicker noise suggests that the **dynamics** of the system are strongly influenced by past **events**. In contrast, **white noise**, a **random signal**, implies no **correlation** between the current **dynamics** and past **events**" (1991, p.28).

They add: "The theory of **self-organized criticality** suggests a rather general interpretation: flicker noise is a superposition of **signals** of all **sizes** and durations - **signals** produced when a dynamic (**composite**) **system** in a **critical state** produces chain reactions of all **sizes** and durations" (Ibid).

The flicker noise expresses an inverse relation between the **amplitude** of **fluctuations** and their number. Small **fluctuations** are very frequent and numerous, while giant ones are very rare.

The concept has been applied to earthquakes by B. GUTENBERG and Ch. RICHTER. The GUTENBERG-RICHTER law says that: "The number of earthquakes each year that release a certain amount of **energy** E, is proportional to 1 divided by E to the power of b where the exponent b is about 1,5. The exponent b is universal in the sense that it does not depend on the particular geographic area. Hence, large earthquakes are much more rare than small ones" (BAK & CHEN, p.29).

The comparison for example, with stock's quotations **fluctuations**, **populations variations**, or even social unrest, leads to the insight that small and frequent releases of tensions avoid the crossing of more dangerous **instability thresholds**. When they do not occur or are much delayed a **runaway event** becomes unavoidable and leads to an explosive release of pent-up **stresses**.

BAK and CHEN report that B. MANDELBROT has found **fluctuations** in the DOW JONES index, similar to flicker noise (Ibid).

→ **Criticality; Elliot wave**

1293

FLIP-FLOP device ²⁾ - 5)

Any **control** that switches between two opposite positions.

Most flip-flops are electronic **circuits**, but many natural systems are also able to switch through **phase transitions** from one **state** to another. In these cases however, it is frequently impossible to pinpoint any specific **trigger**.

1294

FLOCK

→ **School; Shoal, Swarm**

1295

FLOCKING ¹⁾⁴⁾⁵⁾

A massive **emergent** collective **behavior** among animals and some micro-organisms through which they align their movements in ordered **patterns**.

More generally it is a typical **behavior** of numerous elements in originally **random interaction** within a confined **space** (See M. BUCHANAN, 2000).

Flocking is observed in birds flights, in fish **shoals**, in some bacteria and seems even to correspond to atoms orientation in magnets.

It has been modeled by C. REYNOLDS through a computer **program** applied to a number of "creatures" called **boids**.

REYNOLDS' **algorithm** imposes them three simple **rules**:

- Try to match your direction with your neighbours
- Head for their average **position**
- Don't collide

Flocking appears as an **emergent** property in such a setting.

It appears to be an adaptive collective condition corresponding to a more efficient global use of **energy**. As a behavior it leads to the **emergence** of complex systems at a higher **level**, in accordance with PRIGOGINE's theorem of **minimum entropy production** and HAKEN's so-called **slaving principle**

T. VICZEK, of Eötvös University, in Budapest, and some American researchers, have developed mathematical **models** of this quite frequent **phenomenon** (B. SCHECHTER, 1999, p.30-33)

→ **Crowd Physics; Order from Noise; School; Swarm**

1296

FLOW ¹⁾ - 2)

A displacement of **energy** or **matter** that tends to reduce a difference of **level** or **gradient** between a system and its **environment** or among **subsystems** within the system.

"Flows are defined in terms of the **rates of change** of the **value** of the systems **attributes**" (J.van GIGCH, 1988, p.15).

A flow can be maintained in a permanent way only when the difference of **level** or **gradient** between the **source** and the **sink** is maintained.

For example our planet will be able to maintain and create organized **structures** and dissipate heat toward the external space only as long as the sun maintains its capacity to produce **energy** at a more or less constant **level**.

Any flow involves some work, but altogether a degradation of the **energy** it carries. Any flow corresponds to a well defined **gradient**, to which it is said to be conjugated.

1297

FLOW CHART ²⁾

The graphic **representation** of a **sequence of operations**.

The study of flow charts can be useful for the **evaluation**, eventual simplification and/or restructuration of complex **processes**, particularly in **planning**. See specifically "PERT".

1298

FLOW DIAGRAM ²⁾ - 5)

A feature of J. FORRESTER's **Systems Dynamics**, connecting **levels** (i.e. **states**, in FORRESTER's wording).

FORRESTER writes: "The flow diagram should show how **levels** and **rates** are interconnected to produce the **feedback loops** and how the **feedback loops** interlink to create the system" or still "The flow diagram should show the **level**, **rate** and auxiliary equations and how they are interconnected" (1973, p.7-1).

In **Systems Dynamics**, flows are carrying **matter** or **information**.

1299

FLOW LINE ¹⁾ - 2)

"A transmission line of **information structures** that have engrained within them means of dealing with the **environment**" (S. GOONATILAKE, 1991, p.1).

This concept is inspired by F. VARELA: "(The) **structures** are richly interconnected and the **autonomy** of the lineage is maintained through **time**. The **information** which is transmitted may generally be classified as genealogical **communication**, which conservative **structures** are transmitted down through different **channels**" (Ibid)

This means that flow lines are vehicles for species and societies **autopoiesis**, within **evolution**.

According to E. JANTSCH such **channels** could be DNA, a neural **memory** or **artefacts** (1980, p.197).

The concept of flow line tries to synthesize the very general **process** through which all types of systemic characteristics are conserved and transmitted through **time**.

GOONATILAKE enriches the concept as follows: "The flow lines vary as to their degrees of **rigidity** or **flexibility**. The inner cores are less flexible than the outer ones. The outer cores respond to the **environment** more rapidly than the inner core. The inner core, however, limits the nature of **responses** of an outer core to **changes in the environment**" (Ibid, p.3).

He distinguishes three different types of flow lines:

- the genetic ones;
- the neural-cultural ones;
- the exosomatic ones (p.118-120).

The first line is basic for the existence of the second and the second in turn is the condition for the **emergence** of the third one. "One could depict the evolving **information** flow as a core which gradually adds on concentric **envelopes**" (p.132-3).

And: "In all flow lines **categories** there is a phylogenetic tendency for an increase of **information** and **complexity**" (p.131).

He also observes that **exosomatic** (i.e. technological and cultural) flow lines in human societies tend swiftly to escape to human **control** and to become a very complex **set**, with its own internal logic. Quoting D. MICHIE he states: "Increasingly, the **information** line from computer to computer would assume an **autonomy** of its own, in view of the extensive need for **growth** of new **information** sources and large **data** bases" (Ibid, p.116). We have already witnessed some incidents of this type, as f. ex. the "automatic" crashes in stock markets provoked by cascades of pre-registered stop orders. The Internet is starting to exhibit such **autonomy**, a feature that does not please everybody!

GOONATILAKE also notes that flow lines **co-evolve** with the **information environment** (p.125).

In some sense, his work is convergent with SABELLI's **process theory** and MEYER's **evolutionary acceleration**.

1300

FLOW (Linear)²⁾

A flow whose intensity is directly proportional to the difference of **level** or **gradient** between the **source** and the **sink**.

In those cases in which the **gradient** remains stable, the flow remains steady and the system that uses it is able to maintain its **organization**, or **heterogeneity**, thanks to the steadily absorbed **resources**. Under such conditions, the system evolves toward a **state** in which it maintains its properties through **time**: the so-called **steady state**.

Under the **steady state regime**, the specific production of **entropy** tends to a minimum compatible with the nature of the system's **organization**.

1301

FLOW (Tense)²⁾

A flow that works in a constant stable way without using counter-**aleatory reserves**.

Tense flows are a possibility when the **environment** provides permanently the needed **resources** without excessive variations.

It implies the existence of an internal **adaptive mechanism** within the system that allows it to increase or decrease (within **limits**) its use of the resource in accordance with its **availability**.

It has been discovered for instance that fish, molluscs and shellfishes (crabs, lobsters) have a low **level** of blood oxygenation which allows them when needed, to survive in more or less anoxic environments.

1302

FLOWS and STOCKS²⁾

No flows can exist without the existence of **sources** supplied with stocks, renewable or not.

As to **energy**, the presence of a **gradient** is essential.

As to **matter**, the stocks or **reserves** must be freely available and renewable.

As to **information**, the "stocks" can be **data** banks, behavioral **algorithms**, acquired **knowledge**, etc... In these last cases, there is a curious peculiarity: The flow of **information** does not impoverish the **sources**.

1303

FLOWS SLOWDOWN²⁾

In **complex systems**, flows of **energy** and **matter** are slower than in simpler systems.

Complexity of the system, for example in **ecosystems**, results in an ordered sharing of available **resources** in **energy** and **matter**. Such **order** tends to be **hierarchical**, with some **dominant** species in **control** of the power flow in the **circuit** (but also maximally depending on it).

In this way, the flow becomes *sequentially* divided, or cascaded, between numerous users and more **organization** is obtained with the same final **level** of **entropy** production. In H. ODUM words: "Unless special **energies** are directed to prevent succession, the **complex system** with its specializations performs more work **functions** for a total effort and displaces systems whose **energies** are going into **storage** instead of into useful work for competitive **survival** and **dominance**" (1971, p.112).

As a result, ODUM takes a dim view of man's general "simplification" of the natural systems by suppression of many of their participants. It would however seem that "useful work for competitive **survival** and **dominance**" is what precisely leads **human systems** to this simplification!

1304

FLUCTUATION^{1) - 2)}

A more or less periodical spurt in the **behavior** of a system or a **process**.

Fluctuations of the main **variables** are essential for the **equilibrium** of any system.

There are however two basic, and quite opposed types of fluctuations. In I. PRIGOGINE's words: "Fluctuations on a sufficiently small **scale** are always **damped** by the **medium**. Conversely, once a fluctuation attains a **size** beyond a **critical** dimension, it triggers an **instability**" (1976, p.119).

The first type corresponds to systems in **dynamic equilibrium**. In such cases, fluctuations happen in a more or less **periodic** way and with limited **amplitude** (i.e. tending to **damping**). Indeed, the main condition of **dynamic stability** is that no **value** of any **variable** should cross any defined **critical threshold**. Various types of fluctuations may interfere with each others, producing for the **observer** confusing and quite unpredictable **trajectories**. However, the **global behavior** of the system remains regulated or controlled.

The second type of fluctuations is dominated by **positive feedback**, thus supplied with continuously increasing **energy inputs** from the **environment**, sometimes motored by the system itself. In such cases, the system runs away from its **homeostatic trajectory**, as the fluctuations become ever increasing until a **critical threshold** is crossed. A discontinuous **transition** is then triggered through a last infinitesimal increase of the fluctuation. This may lead either to the demise of the system, as mega-fluctuations can be very destructive, or to a **process** of **bifurcations** and **dissipative structuration** that carry the system towards a higher **level** of **complexity**. (PRIGOGINE's "order through fluctuations"). This author observes: "Unlike **equilibrium** systems, non-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

equilibrium systems do not have a general prescription, like the EINSTEIN formula, to describe the fluctuations. **Nonequilibrium** fluctuations are highly specific" (1984, p.58).

An intermediate **situation** is however possible when the **stability domain** of the system is complex, consisting of various **domains of attraction** which correspond to different internal or external conditions. In such cases, the crossing of a **local stability threshold** implies only a **change of domain**, while global **dynamic stability** is sustained. As emphasized by C. HOLLING this type of fluctuations *enhances dynamic stability*, notably in complex **ecosystems**, whose general **resilience** is thus increased (1976, p.81-4).

1305

FLUCTUATION (Critical)^{1) - 2)}

I. PRIGOGINE states: "We have shown that it is only in the case of **linear systems** that the small fluctuation can be described by POISSON's formula... For **nonlinear systems far-from-equilibrium**, the **distribution** law of the fluctuations of the reacting substances is not that of POISSON.... the fluctuations are **local events**, and one must consider a supplementary **parameter** scaling the extension of the fluctuations. This will be a new characteristic length determined by the intrinsic **dynamics** of the system and independent of the dimensions of the reacting volume. Thus, there is an essential difference in the **behavior** of the fluctuations depending on their spatial extension... This... implies that... only fluctuations of a sufficient extension can attain enough importance to compromise the **stability** of the macroscopic **state** considered.

"Thus our recently developed theory leads quite naturally to the notion of a **critical fluctuation** as a prerequisite for the appearance of an **instability**" (1976, p.117).

PRIGOGINE also states: "It is the fluctuation that can force the system to leave a given **macroscopic state** and lead it on to a new **state** which has a different one" (1976, p.39).

In still another paper, I. PRIGOGINE et al. write: "In dissipative **structures**,... the macroscopic **order** which arises after an **instability** is determined by the fastest growing fluctuation" (1975, p.38).

1306

FLUX²⁾

"A generalized, ordered or **turbulent** streaming" (D. Mc NEIL, pers. comm.).

While generally used as a synonym for "**flow**", this latter is, according to Mc NEIL, a stream of a substance.

1307

FOLD²⁾

A singularity in a 3-dimensional **space** that may generate a **discontinuity** in a **process' behavior**.

The fold-catastrophe is the simplest of the seven elemental **catastrophes** in R. THOM's theory. It has been used in numerous disciplines to modelize sudden shifts between two quite different types of **behavior**.

1308

FORAGING THEORY²⁾⁵⁾

An ecological theory that explains important aspects of animal **ecology**.

Foraging theory's main **rule** is that "animals make **choices** that maximize their "Benefit per unit cost" i.e....they'll expend food gathering **energy** in ways that yield the best energy return"(R. CHALMERS, 2000, p. 39)

Chalmers comments: "The longer a forager exploits one **patch**, the lower the returns will be, until this patch is overgrazed and worthless"...and..."...the optimal **strategy** is to move on when the **rate** of return from a particular patch falls below the average rate over the whole region. This is the **marginal value theorem**...formulated by Eric CHERNOV in 1976"(Ibid.)

In other words, foragers- which are in some sense **parasites** of their **environment**- always try to maximize their rewards.

Of course, the "**whole region**" value must be monitored, which is more easy for an organized **group**...but implies also some **costs**.

It seems that these concepts could be applied in economy. They are surely relevant in cultural anthropology for semi-nomad **groups**. They could also explain the growing trend toward economic migrations, in our time.

Foraging behavior is in fact systemic in a very general sense.

It is clearly associated with the relation between costs and **yield**. A good example is the search for an optimal relation between obtaining relevant **information** and the cost to obtain it, in search time as well as in money.

This can be expressed as "benefit per unit cost".

→ **Commons; Density; Density of occupancy; Hexagonal space filling; Parasitism**

1309

FORECAST (Conditions of)^{1) - 3)}

Anticipation of **events** supposes a **knowledge** of former causal **sequences** and of the general (i.e. **environmental**) conditions of their occurrence. Moreover, two more or less complementary hypotheses are needed:

- that we really know all the relevant conditions in which former causal **sequences** were produced;
- that no new **factor** will appear

This would do for **dynamically stable** systems.

Still, we can never be sure that some **instability threshold** will not be crossed and/or that **bifurcations** will not take place, leading to **dissipative structuration** (i.e. **emergence** of "something" different) or to **chaos** (appearance of one or more unsuspected alternate courses).

Forecasts are most generally based on logical deduction. However, as noted by E. JANTSCH: "Logical deduction is always **linear** and partial by its very nature, since it tends to isolate a single aspect of reality" (1975, p.203). As a result, traditional ways of forecasting are of dubious value (and in many cases little more than a mirror for wishful thinking). Even more sophisticated ones are still far from being totally trustworthy.

1310

FORECAST (Limits to)^{1) - 3)}

Forecast and **planning** are possible at different **time** horizons.

Short term forecasts are needed for immediate **action**, but their results are useful at **medium** and at **long term** only if correlated to these last, since **short term action** must be non-contradictory with **medium** and **long term trends**.

These last produce the needed **directive correlations**, but would also be useless if not providing a satisfactory setting for **short term** forecasting and action.

M.P. SCHUTZENBERGER gives an example of this, which he relates to so-called "spans of foresight": "If the man coming down the hill plans each next move according to the details of the next hundred feet he will do better than if he were to plan only over the next ten feet. The spans of foresight are here a hundred feet and ten feet respectively" (1969, p.210).

Of course, **planning** for the next hundred feet is efficient only if a sufficient **knowledge** exists of what is going to happen within the next ten feet and if a satisfactory **integration** of both forecasts can be obtained.

In any case, forecast should be taken with some skepticism, since we never know the whole of a **situation**, nor all the complexities of the **dynamics** of its possible **transformations**. As stated by G. PASK: "... we are not predicting **events**, but certain abstract entities called the probabilities of **events** which can be variously interpreted" (1961, p.19).

Moreover *forecast* is widely different from *prediction*, which is obtained in a scientific sense through the application of strictly **deterministic dynamics** laws to some classes of natural **phenomena**, as for example eclipses.

1311

FORECASTING¹⁾

Any rational attempt to predict future **events**.

Forecasting is of course different from divination.

Its results are not, however in many cases much better, because its **methodology** is shaky.

L. DOUGLAS KIEL signals: "The static nature of traditional **linear** and **deterministic models**... provide at best a "snapshot" of reality with, most likely, only **short-term** relevance. The **determinism** generally **embedded** in traditional **linear models** inhibits **dynamics** that may arise over **time**. This can result in naïve **extrapolation** based on **static relationships** between relevant **variables**" (1992, p.35).

This is, for instance, the reason why no high **level decision maker** had any idea that the massive use of insecticides would derive in the **selection** of resistant varieties of pests or even that the appearance of some resistant individuals was a serious problem. Similarly, until AIDS surged, nearly nobody seriously believed that new diseases could suddenly emerge, and still less how and why.

The general cause of this type of problems is that most systems are **nonlinear**, with the result signaled by W.D. GROSSMANN and K.E.F. WATT: "Actual mathematical **chaotic behavior** has indeed been observed since 1976 in most areas of science and in many technological areas. As a consequence it will always be impossible to anticipate everything. It could even be speculated that **unpredictable behavior** of systems might even increase their **viability**" (1992, p.4).

K.DE GREENE proposes an "evolving **system-fields**" **methodology** of forecasting, as opposed to the commonly used "**context-free mechanistic** forecasting" (1991).

He argues that this last **methodology** is obsolete and useless in a world in swift **evolution** and that it leads to "... rather weak and naive" results, of which he gives numerous examples. He states: "... **context-free mechanistic** forecasts often assume an unchanging social **structure**, a continuing preeminence of present kinds of **values** and motivations, and a continuity of the political and economic *status quo*" (Ibid., p.62).

He could even have added ecological status quo.

In his opinion, what we need is a type of "**holistic** forecast (in line with) the concept of **fields within fields** within fields" (p.66), i.e. taking in account differential **trends** at **short**, **medium** and **long term**, whose more or less **periodic** interferences can produce the conditions for considerable and even **catastrophic** quantitative and qualitative **changes** (of which we have seen quite numerous ones during this century).

1312

FORECASTING (Adaptive)¹⁾

St. BEER writes that adaptive forecasting "...is like radar locating **events** in **time** instead of **space**" (1968, p.228)

Forecasts obviously must be permanently revised and adapted, since new **information** frequently becomes available. The usefulness of non-adaptive forecasting dwindles rapidly as **time** goes. This explains why so many apparently well conceived projects end up so wide off the mark.

1313

FORERUNNER SIGNALS¹⁾²⁾⁵⁾

Many unexpected **changes** in **processes** and systems could be predicted, or at least detected with a good **anticipation**, if some specific **events** could be recognized in due **time** as early warnings.

The general problem of **forecasting** is most frequently considered in **terms** of more or less complex **extrapolation** of currently running **trends**, be it at **short**-, **medium**- or **long-term** in some **time scale** adapted to the process under study.

But some changes may be innovative to the point of ending the current trends or introduce some completely new process. The sudden appearance of AIDS in the 1980's or more generally unexpected new kinds of **epidemics** (Marburg or Ebola viruses), or market crashes, or volcanic eruptions are good examples.

In the case of AIDS, for example, the forerunner signal was the abnormal number of Kaposi's sarcomas in California at the beginnings of the 1980's.

However, forerunners signals are discovered only by people able to escape their own routine reactions or even able to react when confronted with some uncommon **events**, or sequences of events.

Nobody can pick up any forerunner **signal** if not aware that some unexpected **situation** could develop. Moreover, forerunner signals are much clearer for trained people than for untrained ones, who even when perceiving some abnormality, are unable to make something out of it.

It is at least partly a matter of **reference frames**.

→ **Change; Cue-Emergence; Forecasting; Power laws; Prospective; Slaving Principle; Term (short, medium, long)**

1314

FORGETTING FACTOR^{2) - 5)}

In markets, the progressive loss of "**memory**" of the system after a period of **time**. (after J. CASTI, 1994, p.106).

This curious feature corresponds to the loss of predictive power that can be obtained from cumulative **data** on the correlative **evolution** of the market. Moreover this factor is different for different stock markets. For example, according to CASTI, its value is 42 months for the NYSE, 36 months in London, 44 months in Tokio and 60 months in Frankfurt. CASTI concludes that: "**chaos** is a major factor influencing price **fluctuations** on the world stock markets" (p.106).

Stock markets and other markets seem to submit to **criticality rules**, which seems to be confirmed by sudden crashes and panics. How and why they lose their "**memory**" remains a good subject for further research.

The forgetting factor could be at work in **living systems**, in **ecosystems** and in **social systems**.

1315

FORM and FORCE^{1) - 3)}

d'ARCY W. THOMPSON wrote (1916): "Form is a diagram of forces". He came to such a conclusion in the following way: "when we abstract our thoughts from the material to its form, or from the thing moved to the motions, when we deal with the *subjective* conceptions of form, or movements, or the movements that **change** of form implies, then Force is the appropriate term for our conception of the causes by which these forms and **changes** are brought about... It is a term as subjective and symbolic as form itself, and so is used appropriately in connection therewith..."

"The form, then, of any portion of **matter**, whether it be living or dead, and the **changes** of form which are apparent in its movements and in its **growth**, may in all cases alike be described as due to the **action** of force" (1916, 1952, p.15-16).

Nowadays the concepts of **energy**, energy **flows** or **energy fields** have more or less replaced the concept of force and we interpret **matter** as local condensations of **energy**. These notions lead us to an interpretation of all systems as a *provisionally permanent* entity condensed within interacting **energy fields** (see "**toroid**", "**vortex**"). Of course, the difference in terminology does not affect THOMPSON's basic views.

A more geometric and static **concept** of form is thus enounced by R. THOM: "Form is always, at long last, a qualitative **discontinuity** referred to some **continuous background**" (1991, p.35).

1316

FORM (Laws of)^{1) - 2)}

"A logical calculus of **distinctions** and **indications**" (K. KRIPPENDORFF, 1986, p.44).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This calculus was developed by G. SPENCER-BROWN (1969). It is basically "an arithmetic whose geometry as yet has no numerical measure: and astonishing as it may seem, the propositions of logic, as well as those of wider and more powerful applications, turn out to be wholly derivable from calculi so constructed" (p. XI).

The real scope of this calculus is still unclear, but SPENCER-BROWN seems to have done for logic in general what G. BOOLE did for binary logic, i.e. give it its general axiomatics and codification.

The first significant derivation of this calculus has been giving a firm formal basis to **self-reference**. This was done by F.A. VARELA (1975). Somewhat later J.A. GOGUEN and F.A. VARELA, applied the **concepts** of **distinction**, **duality** and **complementarity** to systems (1979).

The subject demands a serious study of SPENCER-BROWN's own work.

1317

FORMAL SYSTEM MODEL ²⁾³⁾

"A generalized model of any **human activity system** from the point of view of: taking purposeful **action** in pursuit of a **purpose**" (R. RODRIGUEZ ULLOA, Glossary, 1999).

"It may be used to test the basic adequacy of **conceptual models**" (Ibid)

Of course, all models, including the **human activity system model**, "are intellectual **constructs**... for use in a debate about possible **changes** which might be introduced into a real-world **problem situation**" (Ibid).

Intellectual **constructs** should however be submitted to a rigorous mental technique of the kind proposed by J. WARFIELD, for instance, including the use of **situation complexity indexes**, **subsumptive transformations**, **nominal group technique**, and avoiding **underconceptualization** introduced by **clanthink** and **groupthink**.

1318

FORMALISM (Experimental) ²⁾

The possibility to extract useful formalisms from experiments or statistical inquiries.

After the establishment of some formalisms, it becomes possible to validate it (or refute) through new experiments. This is thus a methodological round-trip.

1319

FOUNDERS EFFECT ^{1) - 4)}

The **long-term dominance** in a system of the characteristics brought into it by its founders.

Such characteristics can be genetic, in **populations**; phonetic, semiotic and **semantic** in **languages**; technical, normative and cultural in societies.

It has been well observed on more or less isolated **populations** of recent historical origins, as for example French Canadians, white South Africans of Dutch stock, or the Kel Kummer succeeded Touareg **group** (A. CHAVENTRÉ and A. JACQUARD, 1974, p.179-93).

Founders have an influence quite disproportionate to their original numbers. They are generally able to transmit their specific and peculiar traits to their descendants.

In a sense, the founders effect is already present in **embryogenesis**. The egg develops along different lines of "founding **cells**" which generate the different **parts** of the embryo" (Eric H. DAVIDSON & al., 1997). According to these authors, no **hierarchical regulation** is needed - or very few anyway - nor a **process** of local specification. It thus seems to be ordering through reciprocal position, creating a **positional value**.

The complete developmental **process**, specially in bilateral living beings is of course much more intricate, as the Hox genes act as **regulators** of the **hierarchic morphogenesis** which determines the ordered plan of the being as a whole.

→ **Homeobox; Morphospace**

1320

FOURIER ANALYSIS ^{2) - 5)}

A mathematical technique created by the French mathematician Jean-Baptiste FOURIER that permits to decompose any continuous **signal** through a combination of various sine **waves**.

A FOURIER series is a sum of terms each with a defined **amplitude** and **frequency**, i.e. a sum of different sine **waves**.

This may lead to arbitrary **representations** as well as to a more or less adequate **model** of some complex **process** through the **cyclical** interferences of sine **waves** that may - or may not - correspond to different interconnected **periodicities**.

This method is also known as "**Frequency analysis**", "**Harmonic analysis**" or "**Spectral analysis**"

K. BOULDING however made the following ironic comment: "... **spectral analysis** (which) is an elegant way of detecting probably non-existent **cycles** and throws no light on the real **structures** and **processes** which underlie **fluctuations**" (1972, p.70).

Indeed, as stated by D. BOHM and F.D. PEAT: "By means of FOURIER analysis, a particular arbitrary form can be built out of **sets** of periodic **waves**, each of which is of a global **order**".

... and: "While each simple **wave** represents a **global order**, when they are put together they add up to produce a complex **local order** as well" (1987, p.161-2).

The problem is that either that global or local **order** is very difficult to explain, or that the given explanation may be baseless. Anyhow, as observed by M. TALBOT, FOURIER transforms are the mathematical analogue of a hologram (1991, p.27).

Unfortunately, due to the resulting controversies about **cycles** and pseudo-**cycles**: "... economists seem virtually to have lost interest in the theory of **fluctuations**" (BOULDING, 1972, 4, p.70).

The subject deserves to be reconsidered, possibly using the **WEIERSTRASS renormalization**, the **deterministic chaos models** and the renewal in **cycles** studies started by K.DE GREENE.

1321

FRACTAL ^{2) - 5)}

A figure that is **self-similar** at different **scales**.

The conceptual base of fractals is **recursive self-similarity** by **scaling**.

Fractals involve **similarities** generated by a **template**, independent of changes of **scales**. They are also characterized by the absence of derivative, an infinity of details, an infinite length and a fractional **dimension**.

The mathematical theory was established by B. MANDELBROT (1983), but numerous fractal figures were described beforehand by various authors, who did not seem to have perceived their common ground:

- LICHTENBERG's figures (18th. century!)
- KOCH's snow flakes and curves
- SIERPINSKI's carpets
- Menger's sponges
- PEANO's curves
- CANTOR's triadic sets

The **WEIERSTRASS function** is also **self-similar** and may lead to fractalized **representations of processes**.

Recently, A. EDWARDS fractalized the VENN diagrams, a very interesting and useful application, for taxonomic uses (1979, p.51-56).

Fractals describe **structures** and are somehow static **objects**, if one is not interested in the order of appearance of their **components** at successive **self-similar levels**.

Fractals are increasingly used to modelize a number of natural **processes**. A recent example is their application to the study of **epidemics** (Ph. Sabatier et al., 1998)

There seems also to be a relation between fractals and **percolation**

1322

FRACTAL AGGREGATION ^{2) - 5)}

T. WITTEN and L.M. SANDER described this method of **clustering elements** in a **fractal** way (as quoted by I. STEWART, 1992): "They started with a single "seed" particle, and created a growing **cluster** by allowing tiny circular particles to attach themselves one at a time.

Successive new particles moved towards the **cluster** in a "random walk", a series of **random** motions in all directions... Wherever the particles hit, they stuck. This **process**, which is known as **diffusion limited aggregation**, or DIA, leads to delicate branching **structures**. Very similar **forms** are seen in nature: not only in soot, but also in the electrodeposition of metals and the **growth** of colonies of bacteria" (p.14).

H. SABELLI observes that the repetition of a simple fractal **structure** allows for the construction of complex and irregular **structures**, starting from a minimal genetic **message**. (pers. comm.)

1323

FRACTAL BASIN BOUNDARIES ²⁾ - 5)

Fractal basin boundaries are **discontinuous** and practically impossible to precisely pin down. They tend to dissolve into a growingly scattered "dust" of points and the **transition** of the system from one type of **equilibrium** to another cannot be properly predicted.

However, by observing, for example, the **WEIERSTRASS function**, it becomes clear that, at any **level**, **thresholds** of **instability** can be defined, at least tentatively, even if no **prediction's** validity can be taken for unquestionably secure.

The relative positions of the **instability thresholds** corresponding to various **levels** must be considered, since it is important in order to emphasize the normal or extreme character of a **situation**.

1324

FRACTAL COMPRESSION

The use of fractals to reduce the volume of **information** that must be treated.

Fractals can be used in this manner because they are **self-referential**: recurring **patterns** appear at different **scales**. Thus, when **information** is distributed at different **levels**, as for example in **images** in video recording systems, the recurring pattern must be stored only once i.e. not repeated in a **redundant** way- and called for use only when necessary at some **scale** or other. (Economist, Apr. 13, 1996, p. 91)

→ **Algorithms (Genetic); Self similarity;- Morphogenetic fields; Randomness (constrained); Search (Random)**

1325

FRACTAL CURVES, SURFACES AND VOLUMES ³⁾ - 5)

The concept of fractalization is now unifying and making clearer a number of geometrical paradoxes which appeared since the end of the 19th Century. All had a common feature: the **emergence** of fractionary dimensions.

1. The CANTOR set: The removal of the central third of a segment, and the reiteration of the same operation on the remaining **parts** produced a **set** of infinitely many points, but their total length at infinity is zero.

2. The von KOCH curve: In this case, starting with an equilateral triangle, constructing on the central third of each side a new equilateral triangle and iterating this **process**, an apparently infinitely long perimeter surrounds a finite area.

3. The SIERPINSKI carpet: "is constructed by cutting the center one-ninth of a square; then cutting out the centers of the eight smaller squares, and so on" (J. GLEICK, 1987, p.101). The **limit**, which would imply the complete disappearance of the carpet can obviously never be reached.

4. The Menger sponge: "is the three dimensional analogue (of the SIERPINSKI carpet)... a solid lattice that has an infinite surface area, and yet zero volume" (p.101).

While these **constructs** are abstract, they are nonetheless extremely useful to understand natural **structures** as diverse as a rocky or sandy coast, the branching of trees and the construction of leaves, the enormous surface of the human lungs, the **Brownian motion** of molecules and, possibly, the **distribution** of galaxies in the cosmos. From an epistemological viewpoint, one should however be aware of the paradoxes of infinity... which are actually as old of Zenon and his arrow.

1326

FRACTAL DIMENSIONS ⁵⁾

A curious consequence of fractalization is the appearance of fractal dimensions, i.e. fractional ones.

The dimension of the PEANO's curve, for example is neither 1, nor 0: it is intermediate, as the one-dimensional line slowly disappears, but leaves a growing number of still related, but not anymore connected points.

Fractal dimensions appear also in natural features.

The fractal dimension of the Norwegian coast, for example, has been calculated as 1,52

1327

FRACTAL GEOMETRY ²⁾

"(A geometry) which models the recurrence of **similar patterns** at different **scales** which characterizes most natural systems" (F. HEYLIGHEN, 1997, p.33)

Fractal geometry was introduced by the French mathematician Benoit MANDELBROT (1983).

HEYLIGHEN comments: "Such **self-similar structures** exhibit **power laws**, like the famous **ZIPF Law** governing the **frequency** of words. By studying **processes** such as **avalanches** and earthquakes, Per BAK (1988,

1991, 1996) showed that many complex systems will evolve spontaneously toward the **critical edge** between **order (stability)** and **chaos**, where the **size** of **disturbances** obeys a **power law**, larger **distributions** being less frequent than smaller ones. He calls this **phenomenon self-organized criticality**" (Ibid).

1328

FRACTAL PROCESS ⁵⁾

"A process that cannot be characterized by a single scale of **time** (a single **frequency**)" (B.J WEST & A.L. GOLDBERGER, 1987, p.364).

To make this clearer it should be added that there is a superposition of **embedded frequencies** at different **levels**. See "**self-similarity**" and **WEIERSTRASS function**.

1329

FRACTAL SCALING ⁵⁾

A process that leads to the development of **self-similar structures** at different **levels**.

This **process** is a very general one and has been recognized in a great **variety** of natural **phenomena**, e.g. numerous biological **structures** in vegetals and animals; of the snowflakes; of coastlines, etc. Fractal scaling has been easily mimicked on computers and could readily be related to some formerly enigmatic topological **forms** (**Fractal curves, surfaces and volumes**), as well as to the "**WEIERSTRASS function**".

1330

FRACTAL TIME ²⁾ - 5)

As **fractal processes** operate through **embedded self-similar** and superposed **frequencies** they necessarily operate within embedded **scales** of **time**.

This can easily be understood by looking at the graphic representation of a **WEIERSTRASS function**.

1331

FRACTIONATION ²⁾ - 3) - 4)

The break-up of a system "into a spectrum of simpler **subsystems**" (R. ROSEN, 1972, p.53).

This term is used by ROSEN, in correspondence with the **reductionist** methodology. He rightly states: "Implicit in this are two crucial hypothesis, of a system-theoric character: namely, that any physicochemical system, however complex, can be resolved into a spectrum of fractions such that a) each of the fractions, in isolation, is capable of being completely understood, and, most important, that b) any property of the original system can be reconstructed from the relevant properties of the fractional **subsystems**. This last hypothesis is demonstrably false for many systems, including

most of those of biological interest. A simple physical counterexample is a system of three gravitating masses in **space** (**three-body problem**)" (Ibid).

Since ROSEN wrote these lines, new complex **models** (**Catastrophes**, **hypercycles**, **deterministic chaos**), better adapted to the global study of complex systems, have appeared.

1332

FRAGMENTATION ^{1) - 2) - 4)}

The **breakdown** of a system into various separated **parts**.

The original **concept** comes from A. TOYNBEE, who applied it to the final destruction of empires, which he attributed to the loss of some critical monopolies.

Fragmentation seems however to be a quite general **phenomenon** related to some types of systems widely extended in **space**, as **populations** or species. It seems to be mostly determined by the severance of **communication** lines, which in turn is generally a result of their overextension and the existence of very different conditions in distant **parts** of the system.

Fragmentation can also be considered as inverse or complementary to the **process** of **percolation**.

For example, a result of general ecological **transformation** of **ecosystems** by man is their progressive splitting into impoverished, ill-connected or disconnected **patches**. Extreme fragmentation may lead to the reduction and even total destruction of some types of **elements**, as they become unable to reproduce and propagate in the fragmented setting.

The same process occurs in archaic societies under the pressure of invaders or colonists.

1333

FRAGMENTATION PROBLEM ³⁾

"Is nature in itself fragmentable, and thereby non-distortively describable, or is it our linguistic **description process** which makes nature appear fragmentable?" (L. LÖFGREN, 2000, p. 15)

This ontological class riddle is obviously insoluble. In any case we generally approach **phenomena** in a fragmented way (as good conceptual descendants of Descartes). And, of course, fragmentation severs **links**, and also partly disgregates our **understanding**.

1334

FRAME ³⁾

A global **representation** of a more or less extended **class** of **objects** or **concepts**.

M. BODEN states: "Frames, as defined in **AI**, are **hierarchical**, for they can include lower-level frames – as 'vertebrate' includes 'bird' and 'house' includes 'room'. Various **slots** are defined within the frame, and specific instances of the general **class** in question are repre-

sented by having different details in the (low-level) slots in the frame. A **programmed** frame will include suggestions for moving around within the relevant part of **conceptual space**" (1990, p.99).

Current **AI** frames are to date more limited than human mental frames.

→ **Reference** (**Frame of**)

1335

FRAME (Mental) ^{2) - 3) - 4)}

A particular mental **model**, which has multiple **components**.

As a basis for his **Global Design and Interpretive Structural Modeling methodologies** J. WARFIELD describes these **components**: "Among the **components**... may be a **model** that defines the **boundaries** and **dimensions** of a **situation** (a "**context**" **model**), a **model** representing the organized **information** about that **situation** (the "**content**" **model**) and a **model** representing a proposed way of changing that **situation** (a "**process**" **model**) These **components** may be implicit or explicit, but they are loosely integrated into a framework" (1989, p.27).

→ **Reference frame**

1336

FRAMEBREAKING ^{2) - 3) - 4)}

The giving up of **part** or the **whole** of a **mental frame**.

Framebreaking is, in many cases, a necessary first step for any **process** of **transformation**. It needs preceed **frame remodeling**, i.e. the development of a new and better adapted way of thinking.

J. WARFIELD writes: "Framebreaking presumes the development of awareness followed by the recognition that some existing way of thinking about a **situation** is not adequate to reform that **situation**. It further presumes a motivation to change the **situation** and the latent capacity to do so" (1989, p.26).

This is a typical systemic way to take distance from one's own prejudices. "It implies at least a willingness to give up old **frames** of thought in order to rethink a field" (WARFIELD, 1990a, p.69).

1337

FRANKFURT SCHOOL ¹⁾

A group of German philosophers and sociologists who took up "Marx's highly political exemplar of critical theory" and reformulated it "into a research program at the Frankfurt Institute for Social Research which began its work in the 1920's. The three main contributors to the early work of the "Frankfurt school" were HORKHEIMER, ADORNO and MARCUSE"(M. JACKSON, 2000, p. 30-31)

I. CRAIB, as quoted by Jackson states: "...the Frankfurt theorists are concerned with the way the system dominates: with the ways in which it forces, manipulates, blinds or fools people into ensuring its **reproduction** and continuation"(Ibid)

After the nazi period and WWII, the Frankfurt School resumed its activities, and its work was continued by the German philosopher Jürgen HABERMAS. It started to gather a growing influence, particularly in France with P. BOURDIEU (1989, 2000, 2001) M. FOUCAULT, J.F. LYOTARD, F. DERRIDA, and others.

M. Jackson offers a quite interesting panorama about the influence of the Frankfurt School in contemporary social theory, even if its work cannot be plainly identified as systemic (2000, p. 30-42)

He observes anyhow that the latest phase to date of german social thought "is found in LUHMANN's highly technocratic, all-embracing and despairing version of **systems theory**. In this, instrumental reason is completely triumphant as everything is subject to the rational requirements of the societal system".

And "Humanity is dragged in the wake of the system"(Ibid, p. 36). A comparison with insect societies seems rather ominous.

→ **Sociality; Stigmergy; Swarm intelligence**

1338

FREEDOM (Constrained) ¹⁾

The limitation to the **degrees of freedom** in a system.

Any **function** in a system must be by necessity maintained within **limits**, for at least two interrelated reasons:

- Any **runaway process** affecting a systemic **function** would quickly endanger the **survival** of the system as a **whole** in the **environment** on which it depends for its **input resources** or for its **output** absorption
- Any such **disequilibrium** in one **function** would quickly lead to dangerous **disturbances** in other **functions**.

→ **General adaptation syndrome; Strain; Stress**

1339

FREE-WILL: A tentative systemic view ¹⁾³⁾

It could be said that the systems **worldview** (or **Weltanschauung**) clarifies somewhat the conditions in which free will could be discussed.

In systemic terms, free-will seems to be a quite constrained possibility, within at least the following conditions:

- Physiological **limits** of various kinds, with finally the enormous, but also limited capacity of the human **brain** to form **concepts** and **values** leading to a considerable **domain** of possible **behaviors**

- **Socio-cultural limits** under the guise of submission to socially accepted values and **norms** whose infringements are severely punished

The possibility of sudden **emergence** of some innovative way of **understanding**, leading eventually to an innovative behavior, introduces still other question marks

On the other hand, free-will corresponds to a **decision** taken by a (supposedly) rational **agent**, at a specific present moment

This is closely connected to the concept of **autonomy** in VENDRYES' sense, i.e. "the capacity of a system to select and decide, within **limits**, its own behavior".

This is done at any moment by selecting one behavior among many possible ones, that become automatically suppressed by the very **act of decision**.

→ **Bayesian probability; Choice; Decision making; Emergence; Nucleation**

1340

FREEZING EFFECT ¹⁾²⁾

A near synonym for "**Jamming transition**".

M. BUCHANAN observes, in relation to traffic jams: "At (some) point, the cars and lorries begin to roll down the road in a solid mass, like molecules locked in a crystal" (2000, p.31).

Freezing effects seem thus to lead to KAUFFMAN's **frozen cores**. A better connexion between both **models** should be considered.

1341

FREQUENCY ⁵⁾

The number of **oscillations** per unit of **time** in a periodic **phenomenon**

In complex **nonlinear systems**, the presence of various simultaneous **processes** accounts for the existence of superimposed periodic **phenomena** and a globally mixed up behavioral curve, wherein the specific frequencies corresponding to the different **processes** are **embedded**.

In these cases, the global aspect of the **process** frequencies appears as irregular.

Complex curves can be studied through **frequency** (or harmonic, or **spectral**, or **FOURIER**) **analysis**, but their decomposition is based either on pre-determined hypotheses, or on pure mathematical technique and, as such, the results are sometimes questionable.

Incommensurability of merely three frequencies in a **nonlinear dynamic system** is a basic factor for the onset of **chaotic behavior**.

1342

FREQUENCY ANALYSIS ⁵⁾

(also known as **FOURIER analysis**, or **FOURIER transform** and **spectral analysis**).

"In theory, any waveform can be described as the sum of sine **waves**, but in practice, the **method** becomes infinitely cumbersome for impulse type **functions**". Moreover: "The **language** of frequency analysis has a "**blind spot**" for the **concept** of "sudden **change**" (i.e., **discontinuous**) (D. Mac KAY, 1969, p.113).

1343

FREQUENCY DOMAIN ²⁾

"A mode of discussion where **events** are not seen as occurring at points in **time**, but rather according to the frequency of their recurrence" (T.F.H. ALLEN and T.B. STARR, 1982, p.268).

1344

FREQUENCY MODULATION ⁵⁾

"A mode of **communication** in which... **signals** are transmitted by varying the number of pulses of a carrier **wave**" (Adapted from J.Z. YOUNG, 1978, p.293).

1345

FROG (Parable of the boiled) ^{1) - 4)}

A parable aimed at showing the danger of unperceived slight, but accumulative **long-term transformations**.

A frog put in lukewarm water very progressively heated, adapts to the slowly increasing heat, until it is too late for escape and becomes boiled.

One wonders if a number of present slow, **long term** and not very perceptible **transformations**, mainly in **ecosystems**, are not equivalent for humankind to the boiled frog **process**.

1346

FROG's EYE EXPERIMENT ^{2) - 3)}

"What the frog's eye tells to the frog's brain" was the title of a seminal and now classical paper presented by J.Y. LETTVIN, H.R. MATURANA, W.S. Mc CULLOCH and W. H. PITTS in 1959. (Proceedings of the IRE, 47, 11, 1959)

These authors showed that the **information** transmitted to the brain is not merely "... a mosaic of light which maps **images** focused on the retina in some sort of geometric **pattern** in the **brain**" (anonymous reviewer in Behavioral Science - Vol 5, nr.3, 1960).

On the contrary: "... the nervous apparatus of the eye itself is designed to detect certain **patterns** of light and... the optic fibers transmit only certain operational **information** about these **patterns** to the **brain**... The conclusions reached were that four separate **operations** are performed on the **image** of the frog's eye and that the result of each of these **operations** is transmitted by a separate group of fibers, uniformly distributed across the retina. The four **operations** are:

1. sustained contrast detection

2. net convexity detection

3. moving edge detection

4. net dimming detection" (Ibid)

Some general conclusions seem unavoidable, covering human sight altogether:

- Visual **perception** is not merely the passive registration of **environmental light flows**.

- **Perception** is highly selective.

- This **selectivity** is based on genetically inherited physico-physiological perceptive devices (which by the way explains, for instance, why different animals have different **ranges** of color **perception**).

- The **brain** reconstructs its own perceptive synthesis in its own way.

- Once learned, perceptive ways become more or less fixed in an **algorithmic** form (see **HEBB's rule**), which is also possibly why and how we form MARIYAMA's **mindscape**s.

As a general consequence, the **observer** is inextricably enmeshed as an active participant of what he/she observes, and so-called **objectivity** must be seriously relativized.

As also noted by J.L. SNELL and W.S. McCULLOCH "... given certain assumptions, **neural networks** could embody logic, **pattern recognition**, **learning**, **purpose** and other mental faculties" (1988, p.360).

Finally, the frog's eye experiment started MATURANA on his way toward the **autopoiesis concept** and its **organizational closure** complement.

1347

FROZEN CORE ²⁾

"A connected mesh of **elements**, each frozen in either the 1 or the 0 **state**" (St. KAUFFMAN, 1993, p.203).

St. KAUFFMAN describes frozen cores as follows: "The frozen core creates spanning, or **percolating** walls of constancy which break the system into functionally isolated islands of unfrozen **elements** cut off from influencing one another by the walls of frozen **elements**" (1993, p.203).

He adds: "Systems may lie in the ordered **regime** with frozen **components**, in the **chaotic** regime with no frozen **components**, or in the **boundary region** between **order** and **chaos** where frozen **components** just melt. The existence of this **phase transition** suggests that the **boundary region** might be a particularly interesting **region** for useful **behavior** in complex **parallel-processing networks**... The central idea is that, if a **network** is deep in the frozen **phase**, then little computation can occur within it. At best, each small unfrozen, isolated island engages in its own internal **dynamics** functionally uncoupled from the rest of the system by the frozen **component**. In the **chaotic phase**, **dynamics** is too disordered to be useful... At the **boundary** between **order** and **chaos**, the frozen **regime** is melting and the functionally isolated unfrozen islands are in tenuous shifting

contact with one another. It seems plausible that the most complex, most integrated, and most evolvable **behavior** might occur in this **boundary region**" (p.219).

As a resulting hypothesis, KAUFFMAN proposes that "**Ecosystems coevolve** to the edge of **chaos**" (p.261).

These views are closely connected with PRIGOGINE's: See hereafter: "**Frozen structure**".

see figure right

1348

FROZEN STATE²⁾

The state of a **part** of a system that becomes permanent.

A frozen state reflects stable **constraints** imposed upon that **part** of the system.

1349

FROZEN STRUCTURE²⁾

A structure that becomes permanent once it emerged.

Frozen structures are a result of **dissipative structuration** in **systems far-from-equilibrium**. They are characterized by a **content** and enclosed into a **boundary**.

I. PRIGOGINE describes the **process** leading to frozen structures: "If the appearance of a certain **sequence** involves overcoming a barrier, then the peculiar conditions at the appropriate **time** will create a particular **sequence** that will then dominate and become permanent" (1984, p.55).

One of the examples given by this author is "The spontaneous appearance of certain sequences of RNA, depending on the **environmental** conditions, (that) has been investigated and experimentally demonstrated by Manfred EIGEN" (Ibid).

→ "Game of Life"

1350

FUNCTION¹⁾

A relation between two terms (E. SCHWARZ, 1993,p.6)

More generally, any function implies a more or less permanent causal **relationship** exerted by some **element** on another element.

This correspond to a **process** – generally **iterative** – that must be carried out to maintain the system's **stability**, its **goal(s)** or general **purpose**, or even, its existence.

The concept of function is closely related to various other ones:

- The **iteration** of a functional **process** evokes the appearance of **sets of elements** permanently interrelated in a specific fashion, namely a **structure**.
- Functional **processes** must be harmonized with each other in the system if it is to maintain itself globally, i.e. as an organized

Figure: see entry FROZEN CORE

From St. Kauffman: 1991, p. 67

whole. They must remain within the **limits** of the **organizational closure** specific of the system.

- Functional **processes** are most generally **cyclical** (i.e., in **homeostatic** systems) and maintain some **critical values** between defined upper and lower **limits**. This is generally obtained through alternating **positive** and **negative** feedbacks.
- Functional processes are frequently interconnected in a circular way, i.e., included in **hypercycles**. A **process** may be **internally** hypercyclical.
- An excessive **stress** endured by a system's function may progressively bear upon other functions and lead to general disabling of the system. See: "**General Adaptation Syndrome**".

In a different perspective, more related to **far-from-equilibrium situations** in systems, I. PRIGOGINE considers that: "**Dissipative structures...** form a bridge between function and **structure**" (1976, p.95). The shaping of new functions and new **structures** are concomitant **phenomena**.

1351

FUNCTION (Canalizing)²⁾

"A **Boolean** switching rule (such as) at least one **input** has a **value** that can by itself determine the **activity** of the regulated **element**" (St. KAUFFMAN, 1991, p.69).

"The **OR** function is a typical canalizing function" (Ibid). According to KAUFFMAN: "Like low **connectivity** or biases in the **Boolean**

rules, an abundance of canalizing functions in a **network** can create an extensive **frozen core**. Increasing the proportion of canalizing functions used in a **network** can therefore drive the system toward a **phase transition** between **chaos** and **order**" (Ibid).

Here **chaos** should possibly be understood as **primeval chaos**, when a system starts its **self organization process**. In **complex systems**, **deterministic chaos** and **order** seem to be the two faces of the same global **behavior**.

1352

FUNCTION CHANGE (Principle of)^{1) - 2)}

The potential in unused **degrees of freedom** to create innovative **functions**.

This principle has been stated and explained by R. ROSEN (1979, p.63), who gives the following example: "Many fishes possess swim bladders, a bag or tissue filled with air, as an organ of **equilibration**. Being a bag of tissue, the swim bladder is vascularized (possesses blood vessels). When air and small blood vessels are in contact, there will necessarily be gas exchange between the blood and the air, and so a respiratory function is incipient in this **structure**".

According to ROSEN: "This Principle of Function Change is thus one of the cornerstones of **evolution** (and indeed of any kind of adaptive **behavior**), and it depends essentially on the fact that the same **structure** is capable of simultaneously manifesting a **variety** of functions" (Ibid).

Function change can be enhanced by increased **variety**, which brings about new **degrees of freedom** – sometimes implicit – and may lead to more **complexity**.

1353

FUNCTION CONSTRUCTION ^{1) – 2) – 4)}

The synthesis of a higher **level** function through **interactions** between elemental units.

J. ERCEAU AND J. FERBER explain that "... elementary units show specific **behaviors** that do not necessarily coincide with subfunctions of the desired function. This latter will emerge from **interactions** between elementary units" (see **eco-behavior**), and, expressing that this is a **bottom-up** approach... "The system does organize itself in order to react adequately in every case, which makes it flexible. Moreover a **breakdown** of one unit does not impair the global working of the **whole**, which makes the system robust" (1991, p.755).

While the authors thus describe a property of **distributed artificial intelligence** systems, the similarity with complex social functions in human **groups** and societies is striking.

1354

FUNCTION (Distributed) ^{1) – 2)}

A function that may eventually be fulfilled by different groups of **elements** within a **complex system**.

In **complex systems** (a species, a **brain**, a society) numerous **groups** of **elements** more or less independent from each others, even when interconnected, are potentially able to fulfill the same function.

Thanks to such a **mode of organization**, the destruction of some **group of elements** does not imply, at least in some cases, the elimination of the function that they fulfilled. After a time another **group** form, able to insert itself into the global **organization** in a new way, and fulfill totally or partially the function.

Distributed functions implies **redundancy** in the system.

1355

FUNCTION (Hidden) ¹⁾

A **function** that cannot easily be discovered and evaluated.

Complex systems may have such hidden functions, corresponding to slow or minimal **processes**. Many recently discovered biological and physiological **regulations** are of this type. Other **regulations**, that act at long or very **long term** also are difficult to discover. Plate tectonics as a geological mechanism has been an example.

In **human systems**, the role of **values**, **norms** and **mindscapes** is still widely undervalued or misunderstood, or even downright ignored, while they may produce unforeseen and sometimes violent and critical **effects**.

1356

FUNCTION (Part-) ²⁾

An **activity** of a system or in an **environment** characterized by **variables** that remain constant over appreciable intervals of **time**. (after W.R. ASHBY, 1960, p.193).

ASHBY comments: "If one looks around one, only in the most **chaotic** surroundings will all the **variables** be changing"... and "...the **environment** of the living **organisms** tends typically to consist of **parts** that are rich in **states of equilibrium**" (Ibid).

Part-functions correspond to acquired **constraints** in the system and to **behaviors** created by **learning** or **training**, in correspondence with the main part-functions in the **environment**.

1357

FUNCTION (Specific) ¹⁾³⁾

The **set of processes** that are exclusive characteristics of some type of **components** in a **concrete system** (adapted from M. BUNGE, 1995, p.34).

BUNGE adds: "This **concept** is necessary... in order not to ascribe any **finality** to things as **cells**, plants, businesses or governments - that cannot conceive **finalities** because they do not have frontal lobes" (Ibid).

1358

FUNCTION (Step) ²⁾

"A function which "has finite intervals of **constancy** separated by instantaneous jumps" (W.R. ASHBY, 1960, p.87).

ASHBY gives some interesting examples:

"1. The electric switch has an electrical resistance which remains constant except when it changes by a sudden jump.

...

"3. If a piece of rubber is stretched, the pull it exerts is approximately proportional to its length. The constant of proportionality has a definite constant **value** unless the elastic is stretched so far that it breaks. When this happens the constant of proportionality suddenly becomes zero, i.e. it changes as a step function.

...

"7. By quantum principles, many atomic and molecular **variables** change in step-function form" (p.89).

ASHBY concludes: "Any **variable** which acts only in "all-or-none" degree shows this form of **behavior** if each degree is sustained over a finite interval" (p.89).

This should be compared with THOM's elemental **catastrophes**.

However, as ASHBY himself points out, "...whether a **variable** of a real **object** behaves as a step-function cannot in general be decided until the details of the **method of observation** are specified" (p.90).

In other words, a **variable** may appear as varying continuously or step-wise according to the **observation scale**.

According to E.von GLASERSFELD, the step function corresponds to "... the unstable **transition** between two **stable regions** given the name of **catastrophe** by THOM. These appear to be reminiscent of the **description** of a **step change** function in ASHBY's **homeostat** and may represent for us the accomplishment of the all-important step function required by ASHBY for his **model** of a **machine** that was both **stable** and capable of **learning**" (1976, p.123).

1359

FUNCTION (The four basic types of constancy in a) ²⁾

W.R. ASHBY distinguishes four basic types of functions from the viewpoint of the extent to which a **variable** displays constancy, namely:

"A. The full-function has no finite interval of **constancy**; many common physical **variables** are of this type: the height of the barometer, for instance;

"B. The **part-function** has finite intervals of **change** and finite intervals of **constancy**;

"C. The **step-function** has finite intervals of **constancy** separated by instantaneous jumps → ("**step function**")

"D. The **null-function** which shows no **change** over the whole **period of observation**.

"The four types obviously include all the possibilities, except for mixed forms" (1960, p.87).

1360

FUNCTION (Transference) ²⁾

A function that describes the relation between an excitation **stimulus** applied to a **mechanism** and the corresponding **response** (After L. BAYLISS, 1966).

BAYLISS applies this notion to biological systems, but its scope is clearly much more general.

1361

FUNCTIONAL COMPARTMENT ²⁾⁴⁾

A **region** in a not clearly structured system where some **elements** of a specific type work together.

This notion has been proposed by M. HOPPERT and F. MEYER (1999, p.518). They give as an example the grouping in a specific area in a prokaryote cell of "the molecules required for a particular **metabolic activity**".

This would be a stage preliminary to the appearance of **membrane**-bounded compartments in the eukaryotes.

The authors add: "Studies... suggest that functional compartments arise spontaneously as a result of the intrinsic properties of the biomolecules themselves and the way they inter-

act with water in the cytoplasm. We have also found that the specific **structure** of water itself can influence the **level** of enzyme **activity** in particular microenvironments".

These **phenomena** seem to be good examples of CSANYI's **autogenesis**, **autogenetic systems precursors** and **zero-systems**.

Functional compartments could probably be used as **models** for the progressive appearance and upbuilding of new **structures** in human societies, specially during the present planetary **globalization process**.

1362

FUNCTIONALISM ¹⁾ – 3) – 4)

The main characteristic of any theory aiming at explaining a system's **behavior** in terms of usefulness, **purpose** or practicality.

R. SNOW writes: "Functionalists view any system in terms of the "job" it was created to do: its **purpose** or **function**" (1993, p.137).

She adds: "A simple example from elementary **communications theory** illustrates the functionalist point of view. Any **communication** system exists for the **purpose** of transmitting **information** from a sender to a receiver. This is its **function**, the essential property that defines it as a system. The sender, receiver, as well as the **information** that passes between them are all **parts** of the system's **structure**. This **structure** is subordinate to the **function** in two ways: 1) it does not serve to define the system and 2) it can be altered significantly – in some cases changed completely – without altering the system's **identity**. So, from the functionalist perspective, a **communication** system would still exist if one sender was replaced by two, or the **information** passed by means of satellite, telephone or shouting" (Ibid).

Functionalism is very close to **1st cybernetics**, as noted by SNOW, who observes moreover that "... **machine images** do pervade much of this (**cybernetic**) literature" (p.141).

Also: "Functionalist theory is replete with **binary** oppositions and logical typing via **categories**" (p.143).

M.C. JACKSON observes that, in the case of **human systems** or **organizations**, functionalists "... study systems from the outside, seek causal regularities, believed that human beings can be understood scientifically and then dealt with as **component parts** of the system, and prefer quantitative techniques of analysis" (1992, p.70).

This **mechanicist** (and **first cybernetic**) view leads easily to manipulation in **human systems**: any "**component**", human or **artifact**, can always be replaced by any other one, similar in functional terms... and there is no more to it than just that. Of course, in such set-

ting, individuals do not positively collaborate; they merely... function.

Within **systemic concepts** and **models**, functionalism offers merely specific ways to **model** some rather limited aspects of systems **behavior**.

1363

FUNCTIONS (basic) of a system (in Systems Dynamics) ⁵⁾

J.de ROSNAY, thus resumes the basic concepts of functions in FORRESTER's **Systems Dynamics**:

"The basic functions of any system are as follows:

"**Flow** (of **energy**, **information** or **elements** are moving from **stores** to **stores**. These **flows** are meted in quantity per **time** unit (figuring **outputs**)... as for example: money **flows** (wages...per month), ...products (cars produced per day)...or people (travellers per hour), or **information** (**bits**... per micro second in a computer).

"**Energy** and **matter's flows** rise or lower the **levels** in the **stores**. They move through **communication channels** and are represented by thick black arrows.

"The **information flows** are represented by dotted arrows. The **informations** are the base for **decisions** which allow for **action** on the **flows**, in order to maintain, increase or lower **levels** in the **stores**.

"**Gates** (or **rates**)... control the turnover of the different **flows**. Each **gate** may be seen as a **decision** center receiving **informations** and transforming them in **actions**: for example a manager, an institution, some **transformation agent** or an enzyme as catalyser.

Such **actions** result in an increase or decrease of the **flows** intensity.

Their symbolic **representation** is a **gate** or tap on a **flow** line.

"**Delays** result of the different velocities of circulation of the **flows**, of storing **periods** in the **stores**, or of frictions between the **elements** of the system. **Delays** play a very important **role** in the **amplification** or inhibition **phenomena**, which are typical of the **complex systems**.

"Finally, there are **information loops**, called **feedbacks**. They play a determining **role** in the systems **behavior** by combining the **effects** of stores (**levels**), **delays**, **gates** and **flows**.

"There are two types of **feedbacks**: **positive** and **negative feedbacks**. The whole **dynamics** of **change** in a system (**Growth** and **evolution** for example) depend on **positive feedback**. **Regulation** and **stability** depend on **negative feedback** (Restoring of **equilibria** and **self-maintenance**)" (1975, p.99-100).

1364

FUNCTIONS OF A SYSTEM (The five basic classes of) ²⁾

Following D. KATZ and R.L. KAHN (1966) the five basic **classes** of systemic functions are:

- **Production**: i.e. **transformation** of the **inputs** into products or services, characteristic of the system;
- **Maintenance**: i.e. obtaining from the **environment** the **inputs** needed to maintain the activities of the system;
- **Manutention**: maintaining the systems internal **coherence**;
- **Adaptation**: production of the **changes** needed to allow the system's **survival** in its **environment**;
- **Direction**: coordination of the **activities** of all the **subsystems** and designing **goals** and means to achieve them.

1365

FUNNEL

→ **Vortex**

1366

FUSCHL GROUP ¹⁾ – 4)

A group of members of various systemics societies who meet every two years in the Austrian town of FUSCHL (near SALZBURG).

The Fuschl Group basic tenet is that systems concepts should be applied in a **useful manner** to the better co-participative (i.e., with the effective participation of all the **stakeholders**) **management** of **human systems**. Its original mentor was B.H. BANATHY. The members, generally about 20 of them, organize themselves in workshops around some 3 or 4 pre-defined thema. Some months before the meeting, each member mails to the others an "input paper" in which she/he states her/his views on the subject she/he selected as of her/his main interest. However, no so-called papers are presented at the meeting, which is entirely dedicated to "open **conversations**".

At the end of the meeting, each workshop offers a statement of its views about the debated subject. A general report is prepared later on for the **International Federation for Systems Research**, which sponsors the meetings.

The members commit themselves to use and promote the practical proposals and **methods** produced by the "**conversations**".

Some of the main thema of the recent **conversations** have been:

- **Development** in systemic terms
- **Models** for a better **education**
- **Models** for a better social **organization**
- **Methodology** of **co-participative design**

Supplementary Fuschl conversations are organized during interim periods, in other countries (Spain, Greece, United States, etc...).

The Fuschl Group also sponsored the publication of the "International Systems Science Handbook" (1993), whose edition was organized by R. RODRIGUEZ DELGADO, founder of the **Spanish Society for General Systems**.

1367

FUZZIFICATION ²⁾ – 3)

"The **operation** (which) has the effect of transforming a nonfuzzy **set** into a **fuzzy set** or increasing the fuzziness of a **fuzzy set**" (L. ZADEH, 1973, p.32).

This operation defined by L.A. ZADEH, results of the application of a specific function called a *fuzzifier* (Ibid).

1368

FUZZINESS: An epistemological evaluation ³⁾

According to M. ZELNY: "Any notion of fuzziness can be meaningful only in dependency on **human systems**, human **observers**, and human tools and **strategies** to describe reality: That is, human beings are the only and exclusive source of fuzziness in **linguistic** labelling – there is no other source" (1984, p.301).

While this is evident, it is also true of any **knowledge** and will remain so until some hypothetical non-human **knowledge** should appear.

Fuzzy **models** try to codify, measure and diminish **ambiguities** in natural **languages** and **labels** and, quoting I.R. GOODMAN and H.T. NGUYEN, we should remember that "The most complex mathematical expressions are meaningless unless they represent concepts at least theoretically expressible in natural **language**" (1985, p.13).

1369

FUZZY ALGORITHM ⁵⁾

"An ordered **sequence** of instructions (like a **computer program**) in which some of the instructions may contain **labels** of **fuzzy sets**, e.g.

- Reduce *x* *slightly* if *y* is *large*
- Increase *x* *very slightly* if *y* is *not very large and not very small*
- If *x* is *small* then stop; otherwise increase *x* by 2" (L.A. ZADEH, 1973b, p.30).

L.A. ZADEH states: "By allowing an algorithm to contain instructions of this type, it becomes possible to give an approximate fuzzy-algorithmic characterization of a wide variety of complex **phenomena**..." (Ibid).

He adds: "Roughly speaking, a fuzzy algorithm is an ordered **set** of fuzzy instructions which upon execution yield an approximate solution to a specified problem. In one form or another, fuzzy algorithms pervade much of what we do. Thus we employ fuzzy algorithms, both consciously and subconsciously, when we walk, drive a car, search for an object, tie a

knot, park a car, cook a meal, find a number in a telephone directory, etc... Furthermore, there are many instances of uses of what, in effect, are fuzzy algorithms in a wide variety of fields, especially in **programming**, **operations research**, psychology, **management science**, and medical diagnosis.

"The notion of a fuzzy **set** and, in particular, the concept of a fuzzy conditional statement provide a basis for using fuzzy algorithms in more systematic and hence more effective ways than was possible in the past" (Ibid, p.38).

1370

FUZZY CLASSIFICATION ²⁾ – 5)

A classification in which the membership of an **element** in a specific **class** do not exclude its membership in another **class**.

For example, a middle size apple could be classified either as "not very small", or "not very big".

1371

FUZZY CONDITIONAL STATEMENTS ⁵⁾

L.A. ZADEH explains how fuzzy **variables** can be described through fuzzy conditional statements: "In particular, if *x* and *y* are linguistic **variables**, the conditional statements describing the **dependence** of *y* upon *x* might read (the following italicized words represent the values of fuzzy **variables**):

- "If *x* is *small* then *y* is *very large*
- if *x* is *not very small* then *y* is *very very large*
- if *x* is *not small and not large* then *y* is *not very large* and so forth" (1973b, p.29).

1372

FUZZY DECISIONAL ALGORITHM ⁵⁾

"A fuzzy **algorithm** which serves to provide an approximate **description** of a **strategy** or **decision rule**" (1973b, p.43).

According to L.A. ZADEH: "Commonplace examples of such **algorithms**, which we use for the most part on a subconscious **level**, are the **algorithms** for parking a car, crossing an intersection, transferring an **object**, buying a house, etc..." (Ibid).

It would be very interesting to know how the **brain** constructs such decisional and behavioral **algorithms**.

1373

FUZZY DEFINITIONAL ALGORITHM ⁵⁾

"A finite **set** of possibly fuzzy instructions which define a **fuzzy set** in terms of other **fuzzy sets** (and possibly itself, i.e. recursively) or constitute a procedure for computing the grade of membership of any **element** of the universe of discourse in the **set** under definition" (L.A. ZADEH, 1973b, p.40).

ZADEH explains: "In the latter case, the definitional algorithm plays the role of an identificational algorithm, that is an algorithm which identifies whether or not an **element** belongs to a **set** or, more generally, determines its grade of membership" (p.40).

1374

FUZZY GENERATIONAL ALGORITHM ⁵⁾

"(An **algorithm** which) serves to generate rather than define a **fuzzy set**" (L.A. ZADEH, 1973b, p.40).

ZADEH states: "Possible applications of generational algorithms include: generation of handwritten characters and **patterns** of various kinds; cooking recipes; generation of music; generation of sentences in a natural **language**; generation of speech" (Ibid).

1375

FUZZY RELATIONAL ALGORITHM ⁵⁾

An **algorithm** that "serves to describe a **relation** or **relations** between fuzzy **variables**" (L.A. ZADEH, 1973b, p.42).

L.A. ZADEH introduces moreover a special **class** of fuzzy relational algorithms, the *fuzzy behavioral algorithms* which are "used for the specific **purpose** of approximate **description** of the **behavior** of a system" (Ibid).

1376

FUZZY SET ⁵⁾

"A **set** wherein there are degrees of membership varying between 0 = not a member and 1 = is a member. The **set** of "tall people" is one such **set**" (T.F.H. ALLEN & T.B. STARR, 1982, p.268).

A more formal definition is: "A **set** *E* with a map *f* from *E* into unit interval [0,1]" (A. KAUFMANN, 1973). C.P. BRUTER, who quotes this definition, adds that "J.A. GOGUEN generalized this notion by considering *f* as a **map** from *E* into a **lattice**" (GOGUEN, 1967, in BRUTER, 1975, p.120).

1377

FUZZY SETS (THEORY of) ²⁾ – 3)

L.A. ZADEH writes: "The theory of fuzzy sets is, in effect, a step toward a rapprochement between the precision of classical mathematics and the pervasive imprecision of the real world – a rapprochement born of the incessant human quest for a better **understanding** of mental **processes** and **cognition**..."

"We have been slow in coming to the realization that much, perhaps most, of human **cognition** and **interaction** with the outside world involves **constructs** which are not **sets** in the classical sense, but rather "fuzzy sets" (or **subsets**), that is, **classes** with unsharp **boundaries** in which the **transition** from membership to non-membership is gradual rather than

abrupt. Indeed it can be argued that much of the logic of human reasoning is not the classical two-valued or even multivalued logic, but a logic with fuzzy **truths**, fuzzy connectives, and fuzzy **rules** of inference" (1973a & 1973b, p.28).

"In our view, it is this fuzzy, and as yet not well understood, logic that plays a basic role in what may well be one of the most important facets of human thinking, namely, the ability to *summarize information* – to extract from the collection of masses of **data** impinging upon the human **brain** those and only those subcollections which are relevant to the performance of the task at hand...

"Thus, the ability to manipulate fuzzy sets and the consequent summarizing capability constitute one of the most important assets of the human mind as well as a fundamental characteristic that distinguishes human intelligence from the type of **machine intelligence** that is embodied in present-day digital computers" (1973b, p.28-29).

Fuzzy sets theory includes fuzzy **subsets**, fuzzy **functions**, fuzzy **categories**, fuzzy **topological spaces**, fuzzy **structures**, etc...

G

1378

GAIA hypothesis ¹⁾

The hypothesis according to which the Earth, as a planet, is a global adaptive and regulated system, in permanent **evolution** as a result of the **interactions** between its physical and living **components**.

This hypothesis has been presented in 1979 by J. LOVELOCK. In his view, GAIA is "... a complex entity involving the Earth's **biosphere**, atmosphere, oceans and soil; the totality constituting a **feedback** or **cybernetic system** which seeks an optimal physical and chemical **environment** for life on this planet. The maintenance of relatively constant conditions by active **control** may be conveniently described by the term "**homeostasis**" (1979, p.11). LOVELOCK writes that his hypothesis: "is in contrast to the conventional wisdom which held that life adapted to the planetary conditions, as it and they evolved their separate ways" (p.152).

Earth **homeostasis** could possibly be accepted in the very general cosmic sense, as an evolutive celestial body that maintains an **oscillating** global **equilibrium** within the solar system. However GAIA itself evolves. As observed by I. PRIGOGINE and P.M. ALLEN: "... the Earth is not in **thermodynamic equilibrium** and... the **flow** of solar **energy** in which it is bathed is sufficient to ensure that for the sys-

tems of interest the relevant **thermodynamic regime** is not that of **equilibrium**, or of **near equilibrium**, but rather that of **far-from-equilibrium**" (1982, p.6).

GAIA hypothesis has generated a considerable current of diverging opinions (See for ex. T. BEARDSLEY – Scientific American, Dec. 1989, p.35-6). Until now, the debate remains open.

To confront all this criticism and in collaboration with A.J. WATSON, LOVELOCK has created "Daisy World", a model meant to justify his hypothesis (1983).

The GAIA hypothesis could possibly be compared with LOTKA's **world engine concept**.

More recently P. BAK emitted the following opinion: "One might think of **self-organized criticality** as the general, underlying theory for the Gaia hypothesis. In the **critical state** the collection of species represents a single coherent **organism** following its own evolutionary **dynamics**. A single triggering **event** can lead an arbitrary large fraction of the **ecological network** to **collapse**, and eventually be replaced by a new stable **ecological network**. This would be a "mutated" global **organism**. At the **critical point** all species influence each other. In this state they act collectively as a single **meta-organism**, many sharing the same fate. This is highlighted by the very existence of large-scale extinctions... Within the **self-organized criticality** picture, the entire **ecology** has evolved into the **critical state**" (1996, p. 155-6)

1379

GAIN ²⁾

The increase of a **process** or **function** resulting of the **action** of a positive **amplification** device.

Gain is basically a term adapted from engineering **control** theory. If the **positive feedback** maintains itself without any countervailing negative one, it amplifies and accelerates the **process**, ending up in a **runaway event**, which may easily destroy the affected system.

For the opposite, see "**damping**"

1380

GAME OF LIFE ²⁾

A game based on a **cellular automaton** whose **initial state** and **behavioral rules** are specified.

J. CASTI, who describes the "game" (1994, p.223-8), observes that it is not really a game, since there are no players; nor are any **decisions** to be made".

P. BAK and K. CHEN describe thus John H. CONWAY's famed game: "The game of life simulates the **evolution** of a **colony** of living **organisms** and mimics the generation of **complexity** in nature" (1991, p.32).

This may be a somewhat overextended claim. As all the **elements** are of the same **class** and all the **rules** apply uniformly in **space** and **time**, it would seem that the game may not be more than a tool for modelling **composite systems** (as opposed to **integrated systems** – see hereafter).

BAK and CHEN pursue: "To start the game, the pieces, or **organisms** are placed at **random** on a board composed of square sites. Each site is occupied by at most one **organism** and is surrounded by eight neighboring sites. To determine the status of any site at each turn, one must count the number of **organisms** that occupy the eight neighboring sites. If one count two live sites around an empty or occupied site, then the status of the site does not change. If one counts three live sites around a site, the live sites give birth to a new **organism** or sustain the life of an old **organism**. In all other cases, an **organism** will die from **overcrowding** or loneliness.

"The game continues according to the **rules** until it comes to "rest" in a simple **periodic state**, containing stable **colonies**" (Ibid).

The game may also end with the total disappearance of the **colony**, or when a final **state** is reached, in which no **change** is anymore possible (analogous to a "**frozen state**").

Other possibilities are: emission of an independent **configuration**, that starts to evolve in its own way, and can at times be absorbed by an "eater"; **self-reproduction** of the original system and, in CASTI words: "... a veritable cornucopia of strange and captivating **patterns**" (p.225).

As a synthesis, the basic conditions of the game are:

- a limited (or supposedly illimited) **substrate** in which its **evolution** takes place
- a specified **structure** of this **substrate** (as for example "square sites")
- an unique type of **elements**, all of them similar
- a given **initial state**
- a **set of transformation rules**, excluding any **change** in the formerly stated conditions

BAK and CHEN perturbed the game "by adding an extra "live **cell**" and found that "the system often sustains long transients of **activity**" (Ibid) ...and that, when measuring "...the total number of births and deaths in the "**avalanche**" after each additional **perturbation**... the **distribution** was found to be a **power law**, indicating that the system has organized itself to a **critical state**.

"We also found that the **distribution** of live sites is a **fractal** that can be described by a **power law**. The average number of active sites within a distance *r* from a given active site was proportional to *r* to the power of *D* where *D* turned out to be about 1,7" (1991, p.33).

1381

GAME (Positive Sum)^{1) - 2) - 4)}

A game which produces net **gains** for one of the players

Truly, any game, when considered *globally* in *time*, should be considered a zero-sum game: The **gains** of some players are the losses of other players.

However, a somewhat viciated concept of so-called positive-sum games has crept within the minds of numerous people, specially in economics.

Interestingly, G. BATESON observes: "A social system is, as von NEUMANN and MORGENTHAU point out, comparable to a non-zero sum game in which one or more coalitions of people play each other and *against nature*. The non-zero sum characteristic is based on the fact that value is continually extracted from the natural **environment**" (1973, p.94)... which, in contradiction with general popular belief, but in accord with the **2d principle of thermodynamics**, is not an inexhaustible treasure chest.

Only by global **recycling**, using available *permanently renewable* sources of **energy**, could this game be maintained. If this is not taken care of, the future generations could face a dire "negative-sum game".

1382

GAME THEORY^{1) - 2) - 3)}

"A mathematical theory devoted to the study of problems of **strategy**, **conflict** and **cooperation**" (M. SHUBIK, 1967, p.151).

K. KRIPPENDORFF describes game theory as "A general theory of rational **behavior** for **situations** in which 1) two (two-person games) or more (multi-person games) **decision makers** (players) have available to them 2) a finite number of courses of **action** (play) each leading to 3) a well defined outcome or end with **gains** and losses expressed in terms of numerical payoffs associated with each combination of courses of **action** and for each **decision maker**. The **decision makers** have 4) perfect **knowledge** of the **rules** of the game, i.e. 1), 2) and 3) but no **knowledge** about the opponent's moves, and are 5) rational in the sense of making **decisions** that optimize their individual **gains**" (1986, p.32).

This "capitalistic" **rationality** is of course a quite narrow view of rational **behavior** (see below).

KRIPPENDORFF adds: "In a **zero-sum game**, one person wins what the other loses. In other **situations gains** and losses may be unequally distributed, which allows the **representation** of numerous competitive and **conflictive situations**".

And "The theory proposes several solutions, e.g., in a **minimax** strategy each participant minimizes the maximum loss the other can impose on him. A mixed strategy involves probabilistic **choices**".

"Experiences with such games revealed conditions for **cooperation**, defection and the persistence of **conflict**." (Ibid).

Games have been used – possibly overused: see hereafter – to modelize specific **situations** in economics and **management science**.

T.R. BURNS and L.D. MEEKER make the following comments about the rules proposed by J.von NEUMANN and O. MORGENTHAU (1964), in the simplest case of a 2-persons game.

"1) The actors lack the will or opportunity in the **action situation** to transform the **structure** of the game, in particular to develop or discover new options.

"2) The actors have alienative or antagonistic social relations – as distinct from having only conflicting preferences (Actors may be in opposition on one **level**, for instance, with respect to **evaluations** of outcomes in a concrete **interaction situation**, without being in opposition on others, for instance, they have solidary **relationships**).

"3) **Stability** is assumed on higher **levels** of **relationships** between the actors as well as on the **level** of their preference **structures** (for which there is an **equilibrium point**)" (1976, p.112).

Synthetically, games are a much simplified **analogy** of real **situations**. Some uses of games may even border the **metaphor** and lead to quite dubious conclusions.

1383

GAME (Zero Sum)^{1) - 2)}

"... a game where the amount of 'winnable goods' (or **resources** in our terminology) is fixed" (F. HEYLIGHEN, 1992, p.4).

Underlying the zero-sum game **concept**, we find the "bank" problem: **resources** are limited and this is critical for unlimited **competition**. In HEYLIGHEN's words: "Whatever is gained by one actor, is therefore lost by the other actor, the sum of gained (positive) and lost (negative) is zero" (Ibid).

On the contrary: "(in) a non-zero sum game all participants can win property from the "bank". In principle, in monopoly, two players could reach an agreement and help each other in gathering a maximum amount from the "bank" (Ibid).

One of the most serious problem of our time is the general implicit assumption – or better said, conviction – that our planetary bank is inexhaustible.

1384

GAMES as problems models^{1) - 2) - 3)}

R.L. ACKOFF scrutinized games as **models** for problems in the following terms:

"A person (or group) can be said to be in a problem **situation** if the following conditions exist:

1. He has one or more unsatisfied desires; that is, he wants something that he does not have, and

2. He has available alternative ways of pursuing the objective(s) and these alternatives are not equally effective: that is, he has a real **choice**.

... "It will be observed that in a game, as conceived in Game Theory, the first two conditions are satisfied. Utilities or valued outcomes are involved, as are unequally effective plays or **strategies**. To have a game, however, several additional conditions are required:

1. the possible plays can be specified in advance.

2. there is a **set** of well-defined end-states.

3. A specified pay-off is associated with each end- **state**.

... "In a game the problem is already formulated for the **decision** maker and hence he is deprived of the **information** which is required to formulate a real problem in this form. In a real **problem-solving situation** the **decision** maker is not given a game to play, he must extract it out of the **situation** itself. A pre-formulated problem is a contrived exercise in which the **decision** maker is presented with incomplete **information**. The procedure by which he does or should solve this exercise it not necessarily the same as what he does or should do in a real problem **situation**..." (1959, p.147-8).

As to the study of real **situations**, see J. WARFIELD's **Generic Design**.

1385

GAMES (von NEUMANN's)²⁾

G. BATESON states very clearly the nature and limits of von NEUMANN's games:

"1) The players ... are by hypothesis, motivated only in terms of a single **linear** (sc. monetary) **scale** of **value**. Their **strategies** are determined: a) by the **rules** of the hypothetical game; and b) by their intelligence, which is, by hypothesis, sufficient to solve all problems presented by the game. Von NEUMANN shows that, under certain definable circumstances depending upon the number of players and upon the **rules**, coalitions of various sorts will be formed by the players, and in fact von NEUMANN's analysis concentrates mainly upon the **structure** of these coalitions and the **distribution** of **value** among the members" (1973, p.94).

Thereafter, BATESON shows why we should be careful in trying to use these **models** in social sciences:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"2) von NEUMANNIAN systems differ from human societies in the following respects:

a) His "players" are from the start completely intelligent, whereas human beings learn...

b) The mammalian **value scale** is not simple and monotone, but may be exceedingly complex (BATESON gives psychological and even biological examples)...

c) In the von NEUMANNIAN system the number of moves in a given "play" of a game is assumed to be finite. The **strategic** problems of the individuals are soluble because the individual can operate within a limited **time** perspective...

d) The von NEUMANNIAN players are, by hypothesis, not susceptible either to economic death or to boredom. The losers can go on losing forever, and no player can withdraw from the game..." (p.94-95).

In synthesis, real social interplay cannot be circumscribed by rigorously limited **rules**, isolated from **context**.

1386

GAP ANALYSIS²⁾

A "**planning** technique used to analyse if and where any gap may occur between plans and reality" (I.G. BLOOR, 1987, p.17).

BLOOR presents the technique as a financial one. It seems however that it could offer quite a wider scope. He writes that any gap "may be attributed to many factors, such as **changes** in volumes of sales, obsolescence in equipment, product or service or any market forces aspects" (Ibid) He defines "gap closing **methods**".

Gap analysis seems applicable more generally to any possible difference between defined **goals** and real **situations**, in the **activity** of any kind of **organizations**. Examples could be the **evaluation** of schooling systems, sanitary systems, traffic systems, etc.

1387

GARDEN OF EDEN²⁾

"An **initial configuration** in a **cellular automaton** which cannot be produced from any previous **configuration**" (P. GREUSSAY, 1988, p.1327).

The **concept** corresponds to the "Garden of Eden theorem", demonstrated by E. MOORE which states that there are **machines** that cannot be built, i.e. that no **machine** exists that can build all **machines**.

Such a "Garden of Eden" **configuration** has been discovered in 1974 by J. HARDOUIN DUPARC from BORDEAUX University for CONWAY's **Game of Life** and demonstrated not to be deducible from any previous **configuration**.

1388

GATE ELEMENT²⁾

A **processor** through which the system receives or emits. the **inputs** or **outputs** which affect its **behavior** (definition adapted from J.L.LE MOIGNE, 1977, p.89).

LE MOIGNE uses this concept, proposed by KLIR and LÖFGREN as a part of his general **model** of the system.

These **processors** constitute a finite **set** : "... they play a specially privileged part in the definition of the "**Système Général**" in view that it is through these that the **Representation System** (i.e. *the observer*) observes the behavioral sequences of the **object** to be modeled (Ibid).

LE MOIGNE adds: "It results from this definition that a **closed system** has no gates (i.e. *boundary*) ! Or in a less paradoxical fashion, that its **environment** is empty" (Ibid).

Let us remember that it would be better to speak of an "**isolated system**", which is a pure **abstraction** and no **model** of any **concrete system**.

1389

GENERAL ADAPTATION SYNDROME^{2) - 5)}

"The manifestations of **stress** in the whole body, as they develop in **time**" (H. SELYE, 1975, p.466).

The G.A.S. is the **set** of non specific reactions of an **organism** submitted to the protracted **action** of some aggressive **agent**.

This concept was introduced in biology by SELYE, according to whom: "The G.A.S. evolves in three distinct stages: alarm reaction, stage of resistance, stage of exhaustion" (Ibid).

The author explains that the second stage develops solely if the aggression and exposure to the noxious agent is not so violent as to produce quick death: "... no living **organism** can be maintained continuously in a **state** of alarm... If **survival** is possible at all, this alarm reaction is necessarily followed by a second **phase**, which I called the stage of resistance" (p.37).

In accordance with P. VENDRYES' **concept** of the use of stored **reserves** to regulate **functions** (biological and in general) during the stage of resistance the system uses part or all of the specific - and in some cases, non-specific - **reserves** at its disposal in order to re-establish **homeostasis**.

If **reserves** are sufficient, the system returns to **homeostasis**. If not, "... after still more prolonged exposure... this acquired **adaptation** is eventually lost" (p.38) and the system enters in a third phase, the stage of exhaustion, which leads it promptly to its destruction.

While this G.A.S. concept and the associated **strain** and **stress** concepts are biological ones, they could quite probably be generalized to psychology, as proposed by F. E. HORVATH

(1959) and social sciences, as suggested by M. Mc LUHAN and by the well known popular dictum: "It was the last straw that broke the camel's back"!

1390

GENERAL EQUILIBRIUM THEORY

→ Nash Equilibrium

1391

GENERAL PROBLEM SOLVER^{1) - 2)}

M. RINGLE synthesizes and evaluates as follows the General Problem Solver Program developed by NEWELL and SIMON: "GPS was designed to extract key features from problems, analyze the logic of the problem, generate procedures for dealing with the problem, and then attempt to solve it. The focus was on the generality of GPS, i.e., its ability to handle a wide range of **situations**, and on its capacity to develop its own **heuristics**. Unfortunately, a careful examination of the major **routines** of GPS reveals that the key-feature analysis depends of the logic found in the "table-of-**connections**" which is pre-programmed, and the technique-generator depends on a selection, by GPS from its "main-**methods**" table. In short, the critical features which would emancipate GPS from the stigma attached to traditional **mechanisms** are obscured but not removed. Given a vague problem to solve (or one which fails to fit into the logical schemata GPS uses for key-feature extraction) GPS is at a loss. Moreover, increasing the size of the table-of-**connections** or the main-**methods** group would not help to answer the initial objection, that the **program** fails to actually "cognize" its **environment**, although it would serve to increase GPS's ability to *appear* cognitive.

"The real problem lies in the fact that the task **environment** for GPS and other AI **programs** is only an "internal **representation**" of the world in a limited way. GPS does not produce its own **symbols** and **values**, but merely manipulates the **symbols** and **values** according to its pre-programmed instructions" (1976, p.8).

In short, the GPS is merely a "Partial Problem Solver" (which of course, is not to be despised).

Generally, this is a result of the necessarily **algorithmic** character of the sequential computers **programs**.

→ "General Systems Problem Solver".

1392

GENERAL SYSTEM RESEARCH: Original program^{1) - 3)}

J.W. SUTHERLAND stated in the following way the original research program of the **Soci-**

ety for General System Research (now International Society for the Systems Sciences):

"- to investigate the **isomorphy** of **concepts**, laws, and **models** in various fields, and to help in useful transfers from one field to another

"- to encourage the development of adequate theoretical **models** in fields which lacks them

"- to minimize the duplication of theoretical effort in different fields

"- to promote the unity of science through improving **communication** among specialists". He added: "The key is the search for **isomorphisms** among real world **phenomena** for these, when identified, permit the development of explanatory **models** or allegories via **analogy-building**" (1973, p.20).

A growing number of systemists deplore that these aims have not been pursued in a really efficient manner. While "systems" – whatever the **meaning** given to this term – were introduced in a number of Universities departments, they were in many cases dismantled (D. McNEIL, 1993a). There seems to exist two principal causes:

- The general **transdisciplinary** systems worldview is *not* a classical subject to be taught as for example micro-biology or astrophysics. As such it does not fit well in any specific curriculum.
- Systemics have been frequently confused with much more limited approaches or subjects, as for example **Systems Dynamics**, **Operation Research**, or **Systems Engineering**. It has also at times been presented as a vague general philosophy, without much specific **content**.

It seems urgent to go back to the original program, as described by SUTHERLAND, avoiding reduction to some specialized applications, as well as academic seclusion. Moreover, systemics, as a **methodology** to understand and manage **complexity**, is for *everybody*, i.e. for businessmen, politicians, economists, ecologists, etc... and also for John and Jane Citizen, from childhood on, in order to enable them to find their way in this ever more complex world.

It should be noted that, since the time SUTHERLAND wrote these lines, a quite different **process** has covered a growing importance: Abstract **models** *invented* principally by mathematicians and logicians, as for example **catastrophes**, **fractals**, **fuzzy sets**, or **percolation** in **composite systems**, led to the discovery of new **phenomena**, or new interpretations of **phenomena**, already known, but until then ill-understood.

But again, the very general **isomorphies** so discovered remain shrouded in specialized mists, unassimilated in their general **meaning** and mostly ignored even by many systemists.

1393

GENERAL SYSTEMS LAWS^{1) – 3)}

General systems "laws" are statements of mostly qualitative nature, as for example W.R. ASHBY's law of **requisite variety**, or J. WARFIELD law of **linguistic drift**.

They are not used to obtain precise or quantitative answers as in physics or chemistry, but to define **relationships** of a general character that can be found in numerous and quite different systems.

They could be considered as memoranda of very general properties, as for example in the case of: "The **whole** is more than the sum of the **parts**" or its complement, as aptly stated by G. WEINBERG: "The **part** is more than a fraction of the **whole**" (1975, p.43).

They are also tools for **generalization** and construction of **transdisciplinary models**. As such, they should be used with restraint, taking carefully in account any special condition that would impede **generalization** or need qualification.

1394

GENERAL SYSTEMS Metaphors³⁾

R.M. SNOW states: "The conceptual scheme of General Systems Theory relies heavily on **organismic metaphors** because of its roots in theoretical biology. All systems are described as one would describe living things, using technical biological as well as developmental terminology.

"Any system, for example, can be viewed in terms of its **life cycle**. All are "born" and subsequently "grow". They pass through "youth" and "maturity" to "death". A system's **self-regulatory activity**, moreover, is analogous to the "homeostasis" of animals and plants. And types or "species" of systems are often described as evolving in either Darwinian or Lamarckian sense" (1993, p.142).

SNOW has however some reservations. She adds: "The systems **community** is able to communicate ...through the mixed **metaphors** they share. There is a problem, however. Few systems theorists are aware of the precision of their **language**, and how it relates the systems sub-schools to each other. As a result, many systemic "texts" go unread by those outside the **field** – or even outside the sub-school in which they are written" (p.149).

Systemists should seek to acquire a deeper **understanding** of the nature and possible uses (or misuses) of their metaphoric **language**.

1395

GENERAL SYSTEMS MODELS^{1) – 2) – 3)}

J.W. SUTHERLAND adscribes the following necessary characteristics to general systems models:

" – The models should have premises which are *fully explicated* such that we, as completely as possible, eliminate any tacit predicates (**axiological**, **ontological**, or **epistemological**).

" – The models should, to the extent feasible or economical, treat all determinants of a **phenomenon** as *endogenous*.

" – The logical or substantive **connections** among the determinants (i.e. **state-variables**) in our models should be both *eidetic* (Note: from the Greek "eidōs": form, shape) and *non-elliptical*.

" – Our models should, to the extent that the properties of the **phenomenon** at hand permit, be *nomothetic* (Note: i.e., usable, from the Greek "nomos": usage, law) in character, but models should always be *apodictical*" (Note: i.e. clearly proven) (1973, p.91).

According to SUTHERLAND, these prescriptions are designed to avoid unwarranted and assumptive **reductionism** (of the kind based on sweeping and invalid **analogies**) and expediency, or, we should add, downright fudging.

We must however assume that the business of replacing enigmatic observed **arrays** of **facts** by comprehensive but very difficult to prove **abstractions**, is quite risky.

As observed by G. WEINBERG: "The most dangerous pitfall in developing **category** systems is imagining that one system of **paradigms** is more "real" than another" (1975, p.34).

General systems models are by nature models of second degree order, i.e. models of properties common to a number of more specific models. For example, **regulation** in general is a global model including the basics of many specific regulations in different disciplines.

As such, it can be used:

- as a **transdisciplinary metalanguage** among specialists confronted by complex **situations**.
- as a tool in any special trade to gain useful insights on overlooked aspects of **phenomena**.

However, as acutely observed by K. BOULDING, one should be very careful as nowadays nobody can: "...hope to know more than a very small fraction of what is known by somebody. The general systems man, therefore, is constantly taking leaps in the dark, constantly jumping to conclusions on insufficient evidence, constantly, in fact, making a fool of himself" (1964, p.30).

... A kind of foolishness we however are in dire need of, if we are not to loose our grasp on complex situations!

1396

GENERAL SYSTEMS PROBLEM SOLVER^{2) - 3)}

G. KLIR refers himself to the General Systems Problem Solver (GSPS), whose: "...kernel... is a *hierarchy of epistemological categories of systems*, which represents the most fundamental *taxonomy* of systems...

"At the lowest level of the **epistemological hierarchy**, we define an *experimental frame* in terms of appropriate **variables**, their **state sets** (**value sets**) and an interpretation of these as real worlds attributes. In addition, some supporting medium (such as **time**, **space**, or a **population**) within which the **variables** change their **states** must also be specified. Furthermore, **variables** may be classified as **input** and **output variables**.

"An *experimental frame* (also called a *source system*) may be viewed as a **data description language**. When actual **data** described in this **language** become available, we move to the next **level** in the **hierarchy**. Systems on this level are called **data systems**.

"When **variables** of an *experimental frame* are characterized by a relation among them, we move to a **level** that is still higher in the **hierarchy**. It is assumed on this **level** that the **relationship** among the **variables** is **invariant** with respect to the supporting **medium** involved... That is, it is **time-invariant**, **space-invariant**, **space-time-invariant**, **population-invariant**, etc...

"We say that a **data system** is represented by a **behavior system** if, under appropriate initial or **boundary** conditions, the support-invariant relation of the latter can be utilized for generating the **data** of the former... A **behavior system** is capable to generate for example, **predictions** or **retrodictions** of the **variables** involved. Moreover, it provides us with an explanation of the **behavior** of the **variables** within the given supporting **medium**.

"Climbing further up the **hierarchy** involves two principles of **integrating** systems as **components** in larger systems. According to the first principle, several **behavior systems** (or sometimes lower **level systems**) that may share some **variables** or interact in some other way are viewed as **subsystems** integrated into one overall system. Overall systems of this sort are called **structure systems**. The **subsystems** forming a **structure system** are often called its **elements**.

"When **elements** of a **structure system** are themselves **structure systems**, we call the overall system a *second order structure system*. Higher order **structure systems** are defined in the same way...

"The key feature of the **epistemological hierarchy** is that every system defined on some **level** in the **hierarchy** entails **knowledge** associated with all corresponding systems on lower **levels** and, at the same time, contains some **knowledge** that is not available in any of these lower **level systems**" (1993, p.32-33).

The interest of the GSPS is that all **concepts** and **models** used in general **systemics** and **cybernetics** can be applied within its **frame**. However, **chaotic systems** should possibly need some general modelling adaptations.

The GSPS should not be confused with SIMON and NEWELL's **General Problem Solver**.

1397

GENERAL SYSTEMS RESEARCH: Operational prescriptions²⁾

According to J.W. SUTHERLAND: "The general systems theorist brings to his discipline or areas of investigation the following operational tenets:

- The postulate that non-mechanical **wholes** are not simple sums (or products) of the properties of their **parts**.
- A preference for a *holistic* as opposed to a **reductionist** analytical modality when treating the "organic" or "**open**" **systems** which predominate in the social and behavioral sciences.
- The concentration on *macrodeterminacy* as an **isomorphic** property of many (or most) **complex systems**, and as a fundamental point for analytical departure.
- The employment of **ideal-types**, **taxonomies** and typologies as fundamental vehicles for the advancement of science in complex phenomenal **domains**" (1973, p.34).

As to the **holistic** modality, it should not be opposed to the analytic one: both seem really complementary. **Holistic** (i.e. **interconnective**) aspects had to be strongly restated, but they are certainly a **frame of reference** for analysis and **reconstructability**, not at all exclusive of specific disciplinary and analytic research, directed to the individual nature of interconnecting **parts** and **elements**.

As to "**macrodeterminacy**", let us remember that the **simultaneity of events** in different **parts** of the **complex system** limits it up to a point, as shown by the theory and models of **chaotic determinism**.

Taxonomies and typologies are certainly very important tools and systems sciences offer a very significant example: J. MILLER's **taxonomy of living systems**.

1398

GENERAL SYSTEMS THEORY^{2) - 3)}

A collection of **concepts**, **models** and **laws** referred to the nature and **behavior** of **complex systems**.

M. BUNGE observes: "Paradoxically enough, this is not a single theory but a whole **set** of theories - **automata** theory, **linear systems** theory, **control** theory, **network** theory, general Lagrangian **dynamics**, etc. - unified by a philosophical framework... We shall call *systemics* this **set** of theories that focus on the structural characteristics of systems and can therefore cross the largely artificial barriers between disciplines" (1979, p.1).

This compiler agrees with BUNGE and consequently, the term "systemics" is generally used in this dictionary in place of the expression "General Systems Theory".

G.S.T. tries to respond to the need to research organized **complexity** and is complementary to the study of organized simplicity (starting with classical mechanics) and inorganized **complexity** (as f. ex. classical statistical physics).

According to I.V. BLAUBERG, V.N. SADOVSKY and E.G. YUDIN, the main tasks of the General Systems Theory are as follows:

- "1. The definition of the "system" concept and all other concepts related to it
2. The **classification** of systems and the discovery of laws pertaining to systems in general and to special **classes** of systems.
3. The construction of **models** (of various degrees of generality) of system **behavior** (functioning, development).
- 4 The development of a special formal apparatus (logical and methodological included) for the solution of problems indicated in (1)-(3) and for formulating the general theoretical foundations of special systems **concepts** such as the theory of **control systems**, the theory of **automata** and the theory of **information systems**" (1977, p.162).

Of course, these very basic tasks should be constantly sustained and validated by the **observation** and study of the numerous **objects** that may be conceived and modeled as systems.

The cited authors add the following comment (by M. MESAROVIC, 1964, p.4,5): "General Systems Theory, as a theory of general **models** must encompass the specific theories concerned with the more restrictive types of **models**; e.g. the theory of **linear systems**, the theory of **Markov systems**, etc. GST also unifies the theories of different aspects of system **behavior** such as **communication**, **control**, **adaptation**, **learning**, **self-organization**, theory of computing and **algorithms**, etc."

"Accordingly, the greatest difficulty in constructing a general systems theory, in MESAROVIC's view is "to find the proper **level of abstraction**" (BLAUBERG et al, p.166).

Possibly, we should work on different **levels** in order to define in every case the most properly adjusted one.

1399

GENERAL SYSTEMS THEORY: a Set of precepts^{1) - 3)}

J.W. SUTHERLAND enounced as an "epistemological platform", the following integrated set of precepts for G.S.T.:

- A belief in the scientific utility of (and the limited existence of) **phenomenal isomorphisms**.
- A belief in the perquisital nature of proper theory, coupled with the conviction that empirical **validation** should be the arbiter of scientific **truth**.
- A postulation of the critical role to be played by **analogic models** in complex **phenomenal domains**.
- A preference for 'organic' referents within the social and behavioral sciences (as opposed to the mechanical referents of classical physics, etc.).
- A preference for a **holistic** analytical modality (predicated on hypothetico-deductive **operations**) as opposed to the **reductionist**-inductivist modality.
- A demand that instances of **macrodeterminacy** among complex 'organic' **phenomena** be fully exploited.
- The postulation that **ideal-type** and **taxonomic constructs** are the most efficient vehicles for **phenomenal** analysis in the social and behavioral sciences" (1973, p.19).

Of course the modes of "empirical **validation**" depend at least in part on the way of setting the "question marks". As to the preference for "organic referents in social and behavioral sciences", it should not be exclusive: **dissipative structuration** and **networks**, for example may provide useful models. As to "**macrodeterminacy**", it became clear, more recently, that **complex systems** combine it with local or **microdeterminacy** in such a curious way as to generate a global **semideterminacy (chaos)**. And "**ideal-types**" and "**taxonomic constructs**" should be used as carefully, as any abstract **construct**.

1400

GENERAL SYSTEMS THEORY: Aims¹⁾

Ludwig von BERTALANFFY summarized as follows the aims of General Systems Theory:

"a) There is a general tendency towards **integration** in the various sciences: natural and social.

b) Such **integration** seems to be centered in a general theory of systems.

c) Such theory may be an important means for aiming at exact theory in the non-physical fields of science.

d) Developing unifying principles running "vertically" through the universes of the individual sciences, this theory brings us nearer to the goal of the unity of science.

e) This can lead to a much-needed **integration** in scientific education.

f) Bringing us closer to the unity of science and the **integration** of scientific education, this theory could provide a basis for a conceptual synthesis capable of fulfilling the time-honored, but presently unfulfilled functions of conceptual guidance and individual and collective motivation. (1956, p.2)".

Through paragraph b), it can be seen that the author – possibly because of an unfortunate translation from German – did not clearly distinguished General Systems Theory from a General Theory of Systems (not to speak of LE MOIGNE's "Théorie du **Système Général**"), which produced later on a great deal of confusion and much controversy. (See "G.S.T.: what does the expression mean ?").

He saw however clearly some conceptual traps that his successors did not always avoided. In D. Mc NEIL's words: "He recognized that a half-baked theory of systems would quickly degenerate into insubstantial platitudes and vapid truisms or be trivialized into mere technology (p.16, p.101). He counseled against purely academic theory, saying that "theory without practice is mere intellectual play" (p.101). He warned against the reification of **models**, e.g. confusing **game theory** with life or misrepresenting exercises as "**problems**" (p.22-3, p.101). He cautioned against accepting analogs and **analogies** as either the complete expression or the definitive proof of systemic theory (p.14, p.35) even if those **analogs** happened to be his own beloved differential equations. He told us not to misapply systemic attributes across **echelons of order**, e.g. to suppose that a **social system** is "living" because its constituents are (p.14). He warned us to eschew **reductionism**, e.g. to mechanical **models** in MKSA units, and to respect emergent irreducibility (p.14) and human **purpose** (p.79)".

D. Mc NEIL comments: "We can also take some advice from several errors which are implicit in von BERTALANFFY's own presentation. Technically, he perpetuates the confusion of "system" with "**structure**" by his emphasis upon formalism and **abstraction** without full acknowledgment of the "**control**" and especially the "**content**" aspects inherent in systems. Philosophically, he does not address the prospect that a rigidly unified systemic **paradigm** might emerge as a tyranny in its own right, imposing "one right way" of thinking that would be at least as harmful as any institutionalized monoculture of orthodox fragmentary sciences" (1993, p.19).

BERTALANFFY acknowledged A. LOTKA's priority (1925) as to the **concepts** of general systemic laws, in the guise of simultaneous differential equations for the definition of complex systems. He gave in his 1955 paper a number of interesting historical references. He was however apparently unaware of A. BOGDA-

NOV's 1922 work in which one can read this striking observation: "In technology and in science, nearly all of the greatest discoveries came from the transfer of **methods** beyond the limits of the **fields** in which they originated" (1980, p.24).

K. BOULDING in turn observed (in 1956) that: "In recent years increasing need has been felt for a body of systematic theoretical **constructs** which will discuss the general **relationships** of the empirical world. This the quest of General System Theory. It does not seek, of course, to establish a single, self-contained "general theory of practically everything" which will replace all the special theories of particular disciplines. Such a theory would be almost without **content**, for we always pay for generality by sacrificing **content**, and all we can say about practically everything is almost nothing. Somewhere however between the specific that has no **meaning** and the general that has no **content** there must be for each **purpose** and at each **level of abstraction** an optimum degree of generality... not always reached by the particular sciences" (1956, p.11).

According to E. LASZLO: "The promise of general systems theory consists in 1) discerning natural systems in diverse areas of investigation, i.e. identify those real **entities** which can be analyzed in terms of general systems laws; 2) providing an inventory of natural systems from atoms to **ecologies** and possibly to **social systems** and the world system; 3) formulating the general principles accounting for the **evolution** of systems on multiple **hierarchical levels**, crossing the **boundaries** of the inorganic-organic, the organic-multiorganic, and their many subdivisions; and 4) referring chosen problems of philosophic-scientific-humanistic interest to the systems analysis of the relevant **phenomena**, carried out in the **context** of the integrated scheme of **hierarchically organized** natural systems" (1974, p.19).

1401

GENERAL SYSTEMS THEORY and Cybernetics^{1) - 3)}

As observed quite early by L.von BERTALANFFY, General Systems Theory should not be confused with cybernetics in general. And still less so with WIENER's much more limited in scope first cybernetics, strictly related to **communication** and **control**. There has however been a growing connection between the two subjects, specially since W.R. ASHBY's "Introduction to Cybernetics" (1956) and M. MARUYAMA's "**Mutual causality**" as **pattern** generator (1963).

W. CANNON's **homeostasis** (1932) also is basically a cybernetic **concept**, while understandable only as a system's property. On the other hand, **positive feedbacks** tend to throw systems out of **dynamic equilibrium** and, as a result, they escape from the cybernetic **mech-**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

anisms of **regulation** and **control**. Classical (i.e. **1st order**) **cybernetics** could thus be evaluated as the province of the **homeostatic systems**.

von FOERSTER **cybernetics of 2nd order** as well as PASK's cybernetics of **cognition** and **learning** and, later on, MATURANA's **autopoiesis**, while having their roots in cybernetics, are in fact systemic theories.

G. KLIR, in turn, describes as follows the innovations introduced by G.S.T:

"1. A new way of looking at the world has evolved in which individual **phenomena** are viewed as interrelated rather than isolated and **complexity** has become a subject of interest.

"2. Certain concepts, principles and **methods** have been shown not to depend on the specific nature of the **phenomenon** involved. These can be applied without any modification, in quite diverse areas of science, engineering, humanities and the arts, thus introducing links between classical disciplines and allowing the concepts, ideas, principles, **models** and **methods** developed in different disciplines to be shared.

"3. New possibilities (principles, **paradigms**, **methods**) for special disciplines have been discovered by making investigations on the general level." (1969, p.16).

In the first years of G.S.T. (and **cybernetics**), this was not so obvious. However, during the last twenty years, or so, the conceptual "tool-box" has grown apace, specially in the mathematical field: **Fuzzy logic**, **Theory of Catastrophes**, **Fractals**, **Percolation theory**; but also from other sources: **Dissipative structuration**, **Organizational closure**, **neural networks**, etc...

1402

GENERAL SYSTEMS THEORY: Epistemological evaluation^{1) - 3)}

M. BUNGE proposed an epistemological evaluation, not of "a" General System Theory, but of the different General Systems Theories in existence, as for example "... the statistical **theory of information**, **game theory**, **control theory**, **automata theory**, and even the general Lagrangian framework, the general classical theory of **fields**, and the general quantum theory of **fields** (misnamed "axiomatic field theory") (1977, p.32).

He considers that: "All of these theories are **phenomenological**, i.e. are **mechanism-free**... Hence, they can describe the **behavior** of certain systems but not explain how they work. Moreover they are **stuff-free** - i.e. they make no detailed assumptions concerning the nature of the **components** of the systems concerned. Whence their extreme generality" (Ibid).

As a result, G.S.T. have no specific predictive power, unless complemented with "extra **knowledge** concerning the composition" of the specific system under consideration.

BUNGE gives an example, inspired by the case of the **TURING Machines**, "which being equipped with infinitely long tapes, are strictly speaking unrealizable".

As a result, "... while **automata theory** is *applicable* (by specification) and moreover guides much of advanced engineering **design** and even some psychological research (SUPPE), it is *irrefutable*. It is not even confirmable in the traditional manner of predicting and checking: the theory makes no specific **predictions**, it prohibits hardly any **event**, and it suggests no experiments other than *Gedankenexperimente*" (i.e. Thought experiments as proposed by EINSTEIN) (Ibid).

In short, concludes BUNGE, G.S.T.s are "*empirically untestable*".

He admits however that they can be bettered: "In fact, G.S.T.s are *corrigible* if not exactly refutable in the light of empirical evidence. To begin with, they can be improved upon formally. i.e. logically or mathematically... Or they can be made more complex in an attempt to fit better their intend referents" (Ibid., p.33).

While not confirmable in traditional manner, they can be, according to BUNGE, confirmed *conceptually* and also *practically*. "Thus general **network theory** is confirmed conceptually by being shown to capture the traits common to all **nets**, whether physical or **informational**. And it is confirmed practically by being used in the **design of nets** of some kind" (Ibid., p.34).

Without being the following truly a **confirmation**, it should also be noted that **network models** make sense and can be used for acquiring a better **understanding** of some systems in which very numerous **elements** are connected in a semi-permanent and more or less probabilistic way, as for example **social systems**.

BUNGE states moreover that "G.S.T.s are so many frameworks that must be adjoined specific **models** of the system of interest before they can be of any use. For example, in the case of **information theory** we must be able to identify at least the **sources of information** and of **noise**, the **channel**, and the **receiver**; and we must have a **code** for the system of **signals**" (Ibid).

(Let us observe, by the way, that BUNGE, no doubt, speaks here of SHANNON's *communication theory*)

"In other words, a member of the G.S.T. **class** becomes a specific theory of the standard type, perhaps a scientific theory, when enriched with specific **information** concerning the system to which it is applied".

And "G.S.T.s are confirmed a) by fitting all families of specific theories (*conceptual confirmation*) and b) by helping in the building of specific theories that are tested the classical way (*indirect confirmation*)" (Ibid).

Finally: "G.S.T.s are *generic frameworks* helping one to think of entire genera of entities in a **variety of domains**, from biology and psychology through hardware and human engineering to city **planning** and politics. True G.S.T.s solve no particular problems without further ado - but on the other hand they help in the discovery and formulation of new problems and they clarify basic ideas in all fields of inquiry" (A. RAPOPORT, 1972, p.74 - as quoted by BUNGE).

1403

GENERAL SYSTEMS THEORY: History¹⁾

It could be said that there was a pre-history of systems theory, in which early isolated authors developed systemic and cybernetic concepts without being aware of each others and were forgotten or presumably unknown by the "founding fathers". Such are the cases of:

d'ARCY W. THOMPSON, whose fundamental work on "**Growth and Form**" (1916), reprinted in 1952, can be viewed as the first attempt to use **homomorphies** and **isomorphies** systemically.

A. LOTKA, whose "Elements of Mathematical Biology" (1924), reprinted in 1956, offer a synthesis of his original **concepts** about **growth**, **equilibrium**, general **evolution** and natural **cycles**.

A.A. BOGDANOV and his "Essays in **Tektology**", forerunner of cybernetics, first published in Russian in 1921 and translated only in 1980 to English.

J.C. SMUTS, the South African general and statesman, who published in 1926 his seminal essay on "**Holism and Evolution**", reprinted in 1973.

W. CANNON, who in his "Wisdom of the Body", probably inspired from Cl. BERNARD's concept of "milieu interne", formally introduced in 1932 the concept of **homeostasis** in biology.

Another milestone was the solution of the **MAXWELL's demon** paradox by L. SZILARD in 1929, who showed the fallacy of the supposed possibility to do some work without any **source of energy**.

Still other precursors were S. ODOBLEJA, with his "Cybernetic Consonantist Psychology" (1938) and P. VENDRYES with his theory of **regulations** and **autonomy** (1942).

J.van GIGCH resumes the early history of G.S.T. as follows: "General Systems Theory did not originate with just a handful of thinkers. Several currents were present at its inception. Concepts connected with **open systems** were developed concurrently in **thermodynamics** and biology in the 1930s" (1978, p.58).

From 1929 on L.von BERTALANFFY and J.H. WOODGER proposed the basic **concepts** of organismic biology, that were to lead BERTALANFFY to the first definite formulation of a General Systems Theory in 1950. (See bibliography in L.von BERTALANFFY (1949 & 1950).

van GIGCH pursues: "**Equifinality** was introduced by von BERTALANFFY in 1940. The contrast between inanimate and living nature was described by BRILLOUIN in 1949. Examples of **open systems** in ecology, neurological systems and philosophy were made evident in the 1950s in publications by WHITACKER, KRECH and BENTLEY respectively.

"General Systems Theory is the result of other fundamental contributions such as those of:

"1. John von NEUMANN (1948), who developed a General Theory of **Automata** and laid the foundations of **Artificial Intelligence**.

"2. C.E. SHANNON's work in **Information Theory** (1948), by which the **concept** of amount of **information** was developed around **Communications Theory**.

"3. Norbert WIENER'S **Cybernetics** (1948), by which the **concepts** of **entropy**, **disorder**, amount of **information** and **uncertainty** were related to each other and their importance emphasized in the **context** of systems.

"4. W. Ross ASHBY (1956)... developed the **concepts** of **Cybernetics**, **self-regulation**, and **self-direction** around the ideas originally conceived by WIENER and SHANNON" (p.58-9).

van GIGCH also traces sources outside **thermodynamics**, **biology** and **cybernetics**:

"KOEHLER represents the early attempts to state the manner in which systems properties regulate the **behavior** of the **components** and, hence, the **behavior** of the system.

"REDFIELD ... brings out both the **continuity** and the great **variety** and **complexity** of the transitional bridging the biological and socio-cultural **levels**" (p.59).

Still other important precursors were:

B. RUSSELL and A.N. WHITEHEAD whose **theory of logical types** cleared the way for a better theory of the **observer** and for **constructivism**.

KOEHLER, KOFFKA and others represent the contribution of **Gestalt** psychology.

A. ANGIAL, as early as 1941, formulated very clearly the basics of a "logic of systems" (1969, p.17-29).

E.A. SINGER's studies about **mechanicism**, **vitalism** and **naturalism** (1946) were influential on C. WEST CHURCHMAN, R.L. ACKOFF, J.van GIGCH and others.

A detailed history of Systemics and Cybernetics does not yet exist and would be a timely contribution to the history of 20th century's science and philosophy of science.

1404

GENERAL SYSTEMS THEORY (Innovations introduced by the)¹⁾

According to J.van GIGCH: "General Systems Theory meets the objections raised against the analytic-mechanistic approaches and accomplishes the following:

"1. It takes a **holistic** approach to systems by preserving their **identity** and the properties of irreducible units.

"2. It raises the generality of particular laws by finding **similarities** of **structure** (**isomorphisms**) across systems, regardless of disciplines and the particular science in which they are found.

"3. It encourages the use of mathematical **models**, which offer a **language** devoid of **content** but which can, by their generality, suggest **analogies** or lack of **analogies** among systems... The limits of this approach is the lack of faithfulness of the mathematical **models** to the realities of the systems.

"4. It promotes the unity of science by providing a "framework of **coherence** for the organization of **knowledge**" (RAPOPORT). It can act as a "system of systems" to point to gaps in special fields and to **similarities** across disciplines (BOULDING)" (1978, p.48-9).

van GIGCH developments on these points are of great interest.(1978, p.55-75).

1405

GENERAL SYSTEMS THEORY: limits to its algorithmization^{2) - 3)}

N. KASKOV, quoted by I.V. BLAUBERG et al, "demonstrated that the following mass problems could not be solved in the framework of the general systems theory: - to construct

- an **algorithm** allowing to find all the **elements** of any given system;
- an **algorithm** allowing to find all the **connections** of any given system;
- an **algorithm** allowing to determine the **structure** of any given system;
- an **algorithm** allowing to determine all the **functions** realized by any given system" (1977, p.205).

Of course, neither could any other theory produce any such **algorithms**.

Such a result seems perfectly logical, in view of the massive **non-linearity** of **complex systems**. KASKOV's statements are quite interesting in relation to FORRESTER's **Systems Dynamics** and to **Systems Analysis** in general.

→ **Petri networks**

1406

GENERAL SYSTEMS THEORY: Mathematical aspects^{1) - 2)}

A. RAPOPORT sees G.S.T.: "as an effort to fuse the **mechanistic** and the **organismic** approaches so as to utilize the advantages of each. A system is not merely a totality of units (particles, individuals), each governed by laws of **causality** operating upon it, but rather a totality of **relations** among such of these units. The emphasis is on organized **complexity**, i.e.,

on the circumstance that the **addition** of a new **entity** introduces not only the **relation** of this **entity** to all others but also modifies the **relations** among all the other **entities**" (1966, p.5).

As a result, as stated in the same paper by RAPOPORT, the mathematics of the simple **linear causal relations** is not anymore useful, and may even become quite misleading. Fortunately, during the last 30 years a number of new (or renewed) mathematical formalisms did emerge:

- expanded **graph theory**
- **catastrophe** theory
- **fuzzy sets**
- **fractals**
- **deterministic chaos**

... all of which offer new insights into dynamic **behavior** in **networks** of **interdependent elements**.

M. MESAROVIC gives the following syntactic definition of a general system: "A general system is defined by:

1. A **set** of implicitly defined formal **objects**
2. A **set** of elementary **transformations** *T*
3. A **set** of **rules** *P* for forming the sequences of *T*
4. A **set** of statements indicating initial forms of the formal **objects** for use in generating new forms of the **objects**" (1964, p.7).

This definition seems too deterministic in view of more recent developments.

1407

GENERAL SYSTEMS THEORY: Some axioms (C.W. CHURCHMAN) (1963)^{1) - 3)}

According to CHURCHMAN: "The intent of the axioms is to state two things:

- 1) that systems are complexes that can be designed and evaluated, and
- 2) that the adjective "general" in the phrase "general systems theory" modifies systems, as well as theory" (1963, p.173).

Hereafter, the nine axioms of CHURCHMAN are given:

"1. Systems are designed and developed" This statement implies that systems are man-designed, which seems seriously restrict and one would say, unduly so, the possible uses of systemic **models**, as applied to various kinds of **non designed concrete systems**.

"2. Systems are **component** designed". Confirming the first axiom, CHURCHMAN states: "The designer conceives a **design** as consisting of a **set** of subproblems, the solution to each subproblem leading to a **component** of the larger system"(ibid).

"3. The **components** of systems are also systems". This could be called the "matrioshka postulate". However, just as the "matrioshka"(or **fractals**!), it should end somewhere and somehow.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"4. A system is closed if its **evaluation** does not depend on the **design** of its **environment** within a specific **class** of **environments**". Being this a tall order, CHURCHMAN adds: "Usually the designer does not attempt to account for all possible **environmental changes**. If he does, then we have the following:

"5. A General system is a system that is closed and ... remains closed for all possible **environments**". We obviously pass here from the **model** based on a concrete **situation** to a totally abstract one."

CHURCHMAN'S four last axioms are avowedly philosophical and most generally debatable:

"6. There exists one and only one general system (Monism)".

"7. The general system is optimal (optimism)"(!) CHURCHMAN states thereafter the following quite idealistic belief: "The most general task of system **design** is to approximate a general system".

"8. General system theory is the **methodology** of searching for the general system".

This statement should be compared with BLAUBERG's et al opinions about General Systems as theory or **methodology**.

"9. The search becomes more difficult with time and is never completed (realism)".

1408

GENERAL SYSTEMS "THEORY": Theory or methodology ? ^{1) - 3)}

If the **concept** of "General Systems" is needing a clear scientific status, it would seem that no definitive agreement has yet been reached in this sense.

In 1977, I. BLAUBERG et al wrote: "Neither BERTALANFFY's conception nor, incidentally, the subsequent evolution of research in the general system theory has been able to resolve the dilemma "a scientific and technological theory or a **methodology**". Inasmuch as everything investigated in science may be represented as **sets** of interconnected **elements**, the system **concept** has a universal significance, while attempts at constructing a universal scientific and technological systems theory will probably be reduced to truisms" (1977, p.193).

... and "...the general system theory as a **methodology** of investigating system **objects**: 1) is deprived of the status of a scientific theory, and 2) can be developed successfully only in the presence of systematically formulated and sufficiently rich systems theories and under the conditions of constructing a specific methodological **language** and the conceptual apparatus of research" (Ibid).

One basic difficulty seems to be rooted in the limits given to the significance of the system **concept**. It does not appear to be true that "everything investigated in science may be represented as **sets** of interconnected **elements**", or at least, not all **interconnexions** are **complex**.

There are different types of concrete systemic **situations** or systems, as for example, **composite**, **autopoietic**, **isolated**, **open-closed**, etc... for which we need different **models**. However *all* of these **models** have some common characteristics: a complex **structure** in **space** and **time**, **non-linearity** and **regulations**, a permanent identity.

On the other hand, during the last twenty-plus years a growing number of specifically systemic descriptive instruments did appear: **systems dynamics**, **reconstructability analysis**, **catastrophe theory**, **fuzzy sets**, **fractals**, **percolation**, **deterministic chaos**... which can be considered as a "tools box" of **models**.

One wonders if BLAUBERG et al would still maintain their opinion today (2004). It seems indeed that we are well on our way toward a general system theory (i.e. a general theory of **complex systems**) and methodology (having and using specific new **models** for the study and **management** of complex **situations**).

1409

GENERAL SYSTEMS THEORY: What does the expression mean ³⁾

R. RODRIGUEZ DELGADO writes: "According to BERTALANFFY "General Systems Theory" is a new science of **organization** and **wholeness**. He postulates the legitimacy of seeking a theory, embracing universal principles, valid for "systems" in general.

"One of its main consequences is the detection of structural **similarities** or **isomorphisms** in different fields as for example the exponential law of **growth**, the theory of non-organized or organized **complexity** or the general theory of **organization**.

"The classical science tried to explain **phenomena** by isolated causal chains or by statistical results due to **randomness**. However this science is not sufficient for the understanding of the **interactions** of a great number of **elements** or **processes**, which demands new types of mathematical and logical thought, to be added to those already in existence.

"This germinating thinking has been enriched and encompasses now the **information** and **communication theories**, **cybernetics**, **net theories**, stochastic **models**, **bifurcations** theory, **multicausality**, **uncertainty** and **complementarity** principles, **order** and **chaos theories**, etc.

"Generally, the authors do not speak about a "General Theory of the System", which would concord with BERTALANFFY's thinking, but of "General Systems Theory"... a way of speaking

which, as observed by CHURCHMAN, is ambiguous in English, in view that the adjective "General" may be applied to "systems" as well as to "theory". As a result "General Systems Theory" could mean a "Theory of General Systems" or a "General Theory of Systems".

"This **ambiguity** could be removed by considering that the "General Theory" includes two different **levels** of generality, just like "Philosophy", which means a global thinking, while it can be simultaneously divided into "Philosophy of science, of fine arts, of law, and even admit new subdivisions as Philosophy of physics, of biology, of painting or of music.

"It is thus convenient to consider General Systems Theory as applicable at any kind of **levels** and any type of systems – natural, human or artificial – even of very reduced size, in view that its characteristics are of universal scope.

"On the other hand, the Theory of the General Systems would include large subdivisions: physico-chemical, biological, social, human, artistic, axiological, ideological systems, etc., which would research the general laws and the emergent qualities of each group, aside from including **interdisciplinary fields** as for example physico-chemistry or molecular biology.

"A study of **emergent** qualities on each **level** gives us a **synchronic** vision (through which systems appear in a clearly differentiated way), as well as a **diachronic** one, (in which it becomes possible to conceive the **evolution** and the mutations of physico-chemical, biological, social, ideological systems, or even of **machines**.

"Of course, so-called "basic **concepts**" are not unshakable principles, but on the contrary concepts that should be considered, elaborated and debated from very diverse angles" (1993a, p. 215-6).

This is a good general summary of the varied approaches of many systemists toward this **epistemological** and **semantic** issue.

1410

GENERAL THEORY OF SYSTEMS ^{1) - 3)}

R. RODRIGUEZ DELGADO, in accordance with his critique of General Systems terminology, proposes this expression and comments: "The General Theory would deal with generalizations applicable to all kinds of systems: conceptual, natural, technological, etc. It would contain also general principles and laws based on rational thinking.

The **boundaries** of a General Theory of Systems would be **fuzzy**, bridging Philosophy with the **General Theory of Systems**. Its curricular content should be clearly established by experts in General Systems Theory.

"A General Theory of Systems should be closely interrelated to a Theory of **Knowledge**, based also on rational and intuitive approaches. A rational **method** means an approach based

in sciences and, specifically in experimental science. Its complement would be a set of intuitions transformed into logical speculations in domains not reachable by reason. We know **knowledge** with our **knowledge**, and this has an *inescapable tautological bias* where reason and intuition met, integrated by intelligence" (1989, p.21).

R. VALLÉE emits a coincidental opinion, arguing that, in 1945, BERTALANFFY introduced his concept in German as "allgemeine Systemlehre" that could be translated as "General science of systems", or "General Systemics" (1991b, p.33).

D. McNEIL holds similar views: "... a general theory of systems must not only be a theory about systems per se but also about how systems are constituted, developed and perceived" (1993a). This author enounces the following program conducive to these aims, and which should include:

"A clear, constructive definition of its subject matter, especially of *system*;

"A succinct, constitutive core of central concepts, expressed at a uniform level of discourse, which are common to every system;

"A conceptual space into which its concepts can be defined and mapped together with a principled way of connecting concepts to one another, within and across **levels** of discourse and **echelons of order**;

"A meta-systemic way to apply the theory transitively to any system and reflexively to itself;

"An orderly way to accomodate the **voluntary mutuality** between the subject, i.e., systems, and the percipients, i.e., humans;

"A method for the ethical application of systemic theory to wholesome life for people and their habitats" (1993, a).

From another viewpoint, in his comparison with other ways to define systems theories in general, L. TRONCALE writes that it requires: "... very broad comparisons across many different **scales** of systems and across many different conventional disciplines; leads to very abstract and qualitative **descriptions** (not properly called **models**) of generalized systems **functions** such as systems **stability**, **structure**, **function**, origins, **development**, **evolution**, **emergence** and **decay**; by emphasizing systems-level **functions** it desemphasizes **component** specific differences of the multitude of disciplinary systems being compared; results are fully **context-independent**; uses the full set of **isomorphies**. However, the lack of quantification leads to much reduced predictive power as regards specifics in favor of broad-scale form..." (1985, p.45).

For M. BUNGE: "The general theory of systems is a *hypergeneral* theory, for dealing with systems of all kinds. And what we have called

generic systems theories deal with entire genera of systems, such as physical, chemical, biological, or social systems" (1993, p.220).

According to BUNGE, "the general theory of properties and the relational theory of space-time" are hypergeneral theories. A relativistic theory of **simultaneity**, or **fractal** theory, would enter in this **class**".

On the other hand "... the general theory of social systems, ... **automata** theory, **information theory**, general **control** theory,... **decision theory** and **game theory**" would be generic systems theories (Ibid).

J.van GIGCH's opinion is more or less, but not completely, in line with BUNGE's understanding: "As LASZLO has clearly pointed out, we should refer to *general system theories* and not to *general systems theory*. The plural should apply to theory and not to system, in that we can conceive of many theories in the field. On the other hand, there is no such thing as a general system and entities called *general systems*. We have also grown accustomed to associating the adjective "general" with "system" in the forms *general system* and *general systems*, instead of associating "general" with "theory" (1978, p.60).

van GIGCH recognizes that he himself "has fallen into this trap by naming this book *Applied General Systems Theory*" (Ibid.).

For an opposite view, based of J.L.LE MOIGNE's work see "**Système Général (Theory of the)**".

This compiler agrees with LASZLO's view, but this historical confusion is now so deeply rooted that it is probably impossible to remedy it.

→ **Volution**

1411

GENERAL THEORY OF SYSTEMS: Performance criteria ¹⁾

L. TRONCALE, who also prefers to speak of General Theory of Systems instead of **General Systems Theory**, proposes the following criteria for its satisfactory use: "It would:

- consist of precisely defined concepts
- be **context-independent**, **invariant** across all **scales of magnitude**, demonstrable in all disciplines
- require the use of the full **set** of **isomorphies**, that is the minimal, sufficient, and necessary **set** (probably large)
- require many specific **linkages** between **isomorphies**
- unobservable in one discipline
- unverifiable, unfalsifiable, even unrefinable, in one or a few disciplines
- apply to both descriptonal and operational views
- describe both **continuous** and **discrete** systems
- be limited in its range of application only by the current state of applied **knowledge**

- possess built-in **rules** for desabstraction, **scale translation protocols**, or correspondence principles
- possess a built-in operational **taxonomy**
- have **isomorphies** and **linkages** that were self-organizing" (1985, p.79).

Most of these conditions do already exist, but merely in an implicit way. It should be the responsibility of every systemist to understand and apply them in order to avoid the very nullification of systemic thinking and of its practical use as a global scientific **methodology**.

1412

GENERALISM ¹⁾

The scientific and methodological viewpoint that centers our attention upon global, complex and interactive **situations** and seeks to reintroduce some general **coherence** within scientific **knowledge**.

L. LÖFGREN quotes the following comment from R. ROSEN: "Such a unification, with the resultant economy of thought, seems absolutely necessary in these days of explosive **growth** in scientific **knowledge**, if the student is not to be hopelessly submerged under the torrent of specific but specialized investigations relevant to his interests. Indeed, unless expanding **knowledge** is accompanied by corresponding conceptual economies, a comprehensive **understanding** of even a small corner of science may become impossible before much longer" (ROSEN, 1970, in LÖFGREN, 1974, p.78).

1413

GENERALIST (Role of the) ^{1) - 4)}

Already in 1955, L.von BERTALANFFY quoted a number of authors who, in 1949, emphasized the necessity to count with generalists and defined their role as follows: "Any research group needs a generalist, whether it is an institutional group in a university or a foundation, or an industrial group. In an engineering group, the generalist would naturally be concerned with system problems. These problems arise whenever **parts** are made into a balanced **whole**" (H. BODE et al, 1949).

R. RODRIGUEZ DELGADO states: "The intervention of generalists is necessary, specially in the first orientation stage. They do not need to be "teachers" in the common sense of the word, but "resource persons" that could advice about the materials in which systemic **concepts** are better expressed, explain difficult subjects, and act as "conciliators" trying to find **complementarity** in **concepts** apparently opposed. They should try to unveil the causes of "real" **conflicts** of interests and ideas... It is

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

convenient to train the learners for finding, by themselves common **sets** of interlinked general concepts related to natural and human sciences, demonstrating their unity and diversity" (1990, p.8).

A generalist is also normally specialized in some field. But he should have a good overall **understanding** of the various disciplines referring to aspects influencing the **whole** to which his/her research is centered (or influencing the significant **environment** of this **whole**). In order to obtain such a reference viewpoint, the generalist needs a **language** of second order or **meta-models** giving her/him the potential to understand **concepts** and **models** used in other disciplines.

The numerous global man-made disasters which occurred before and since the emergence of systemics fully justify these views, which are also applicable to the satisfactory operation of economic, social and political institutions as well as to their complex **interrelations**.

1414

GENERALIZATION^{1) - 3)}

The derivation of a more embracing law, principle, or **method** from a number of specific cases of some **phenomena** or **situations**.

Generalization involves the discovery of some common characteristics, **forms** or **patterns** present into the different **situations** considered. It consists in looking for **homomorphisms** and, if possible for **isomorphic models**, and constructing useful **heuristics**.

However, generalization is antinomic to more precise **distinctions** between the compared **elements**. It should be used carefully.

1415

GENERALIZATION GRADIENT¹⁾

A differential measure in **space** and **time** of the real possibilities to extend the validity of some **model**.

This **concept** has been introduced by M. TODA (1976, p.84). Obviously, unsound generalizations or extrapolations may lead to inadequate results.

However, any practical measure of a generalization gradient seems a quite difficult proposal. Even so, the problem cannot simply be by-passed.

Fuzzy sets theory could possibly be helpful here.

1416

GENERALIZATION (Over-)³⁾

Over-generalization is in many cases the result of excessive enthusiasm with generalization, when its power is recently discovered. M. BODEN observes for example that young children learning the **rules** of verbs tenses start treating

irregular verbs in the same way than regular ones, only to correct this unwarranted generalization later on (1990, p.125).

However, this kind of self-adjusting **mechanism** does not always function correctly and pathological **situations** may arise, as shown for example by A. KORZYBSKI (1950).

Unfortunately, over-generalization seems to breed conceptual short-sightedness, **semantic** muddles, wrong appreciation of **situations** and even twisted or intolerant **behavior**.

1417

GENERATIVE^{1) - 3)}

The general characteristic of any device, **set** of **rule** or set of **production rules** that allows for, or produce a number of useful or significant **combinations**, while excluding others.

Languages, for instance, have a generative **transformation grammar**, defining the ways to form well constructed sentences, using correct words, formed by a reduced number of specific phonemes. In this case, the **hierarchical** nature of the generative system is quite clear.

The various branches of mathematics, as for example arithmetic, geometry, analysis or **topology**, have each a generative system, defining precise **rules** for the construction and **transformations** of their objects of study.

Chess **rules**, harmony **rules** in music, or the generative system of concepts in organic chemistry, produce in the same way **conceptual spaces** to be explored.

Even a culture can be seen as a generative system.

K. KRIPPENDORFF observes: "The use of ... generative devices is **constructivism's** alternative to testing verbal hypotheses and theories with available data" (1986, p.33).

→ **Algorithm; Congruence; Constraint; Creativity; Heuristics and Rule**

1418

GENERATIVE PROCESS

→ **Process Theory**

1419

GENERIC DESIGN SCIENCE¹⁾

The global science of design.

J. WARFIELD states: "Generic Design Science is the whole of design science. It is comprised of all the specific design sciences and the Generic Design Science (itself), serving the universe of design activity. At the present times this concept remains unrealized" (1994, p.20).

The following is a summary by WARFIELD on G.D.S.:

"Generic design refers to the development of outcomes that necessarily are present in the design of anything. Specific design refers to the development of outcomes that necessarily are present for a single design, or for members of a small **class** of designs.

"When design aims to resolve **complexity**, the generic outcomes may often affect thousand or millions of people; hence the route to their development should be based in a science that is responsive to the demands of **complexity**."

"Generic design is such a science. It incorporates the foundational, theoretical and methodological **components** that any science ought to exhibit (if only for purposes of facilitating its **integration** with other sciences, when **aggregation** is needed to serve application)..."

"Because it offers transparency, and evaluative **criteria**, it is well positioned for **assessment** and improvement. Because it offers Laws of Design, it gives focus to **constraints** that will, if allowed to do so, degrade design activity, and lead to disasters" (1995e, p.8).

Generic Design considers the ways designers do design as related to psychological and conceptual aspects, as well as the difficulties proper to design in the general and in specific cases. It adds new dimensions to design and contributes to the **management of complexity**.

1420

GENERIC PLANNING^{1) - 4)}

→ **PLANNING (Generic)**

1421

GENETIC ALGORITHM

→ **Algorithm (Genetic)**

1422

GENETIC PROGRAM OR DEVELOPMENTAL DYNAMICS?

The recently completed sequencing of the human genome introduces again the possibility of a exclusively **reductionist** view of life: looking for ex. for the "gene of schizophrenia". In the extreme view, the gene becomes "the atom of the biologist".

However, in a review of E. FOX KELLER's book "The Century of the Gene"(2000), H. J. RHEINBERGER observes that FOX KELLER "goes so far as to question the very possibility of compressing development into a meaningful **algorithm**"(2001, p. 65)

In his view "the dynamics of **development** and **evolution** will call for an integrated **understanding** of the **organism** as a **whole** and will not be crudely reduced to genetic **mechanisms**"(p. 66) and that "gene technology may well be, indeed must be regarded as an obligatory passage point on the way to a more systemic view of how organisms work, develop and evolve"(p. 66)

We should be attentive in FOX-KELLER view as quoted by RHEINBERGER to the "complexity of the regulatory **dynamics**" that mediate between genetic constitution and bodily performance", lest "the term gene...may even have be-

come, as W. GELBART has suggested, a "hindrance to the understanding of biologists" and perhaps even more of a hindrance to the understanding of lay readers" (p. 66)

Genes are basically **elements**. As such, that can have **position values** and become dynamically associated in **organization process**. It would thus be apt to speak of "developmental **dynamics**-a field quite widely open to further research- better than of "genetic program" (Sh. PENMAN, 2001, p. 66-67)

1423

GENOME and PHENOME⁵⁾

In **living systems**, respectively the inherited potentialities, and the properties acquired during development.

M. BUNGE writes: "... while every organism inherits its genome, it evolves its own phenome in a given **environment**; the phenome depends then upon both the genome and the **environment**" (1979, p.101).

This defines a very general **set** of properties. It would be interesting to consider possible corresponding aspects in enterprises, institutions and other **sociosystems**.

1424

GENOTYPE⁵⁾

The **set** of an **organism's** characters acquired through heredity.

The genotype should be clearly distinguished from the phenotype, as observed by K. KRIPPENDORFF: "The **distinction** is important because it is the genotype, not the phenotype, which is reproduced, but it is the phenotype, not the genotype on which natural **selection** acts" (1986, p.33).

This implies that **autopoiesis** is basically a character of the individual.

→ **Disasters**

1425

GEOGRAPHICAL INFORMATION SYSTEM²⁾⁵⁾

"A **method** of managing computerised **data sets** as different as human **populations**, soil types, tree cover or roads, all referenced to the coordinates of a **map**" (D. MacKENZIE, 1998, p.57).

Such a system is presently installed in the Indian state of Maharashtra. Its objective is to reveal the probable consequences of any possible natural disaster in the making, in order to be able to take in due time protective **action**.

Such a global **information** system is very **cost-effective** when compared with the colossal losses incurred when calamities strike unprepared human groups.

1426

GEOMETRY (Fractal)

→ **Fractal Geometry**

1427

GEOSPHERE

→ **Lithosphere**

1428

GESTALT^{1) - 3) - 5)}

Any **configuration** perceived as a **whole**, with global properties that cannot be assigned to any specific **part**.

Gestalt is a German word meaning **form**, figure or shape, all properties of **wholes**. As such it is one of the main roots of systemic concepts and **models** and of so-called **holism**.

G. PASK offers the following definition: "Some property - such as roundness - common to a **set** of sense **data** and appreciated by **organisms** or **artifacts**" (1961, p.115). This definition emphasizes the perceptual significance but does not elaborate on the proper characteristics of Gestalt.

R.W. FULLER and P. PUTNAM complete somewhat the **concept** in the following way: "The concept of Gestalt has at its core the compounding of a **set** of elementary motor possibilities focussed to a **choice** of specific **act**" (1967, p.105). It results of the **stabilization** of the **relative dominance** of some **perception** cohered through an at least provisionally completed **random search process**.

D. KATZ, quoted by A. LOPEZ GARCIA and M. PRUÑONOSA, summarized a **set** of laws of **form** (not to be confused with G. SPENCER BROWN's **Laws of Form**), as follows:

a. "**Closure law**: lines which close a **space** and which are therefore correlative, tend to be put together...

b. "**Equality law**: if several active **elements** are present, then there is a tendency to put together those pertaining to the same **class**.

c. "**Proximity law**: the union of **parts** which constitute a whole tends toward a minimal interval of **time** or place. Factors b) and c) are correlative as pointed out by KOFFKA (1935, p.164): "... two **parts** in the **field** will attract each other according to their degree of **proximity** and equality".

d. "**Good shape law**: those **parts** of a figure which share the direction or the movement of the **whole** are put together" (1993, p.1197).

These authors translate these four laws to **linguistics** as:

a. an additive **relationship**
b. an equivalence **relationship**
c. a consecutive **relationship**
d. an inclusive **relationship**... between **language elements**.

E. ANDREEWSKY enumerates some "of the most powerful systemic concepts" which originated in Gestalt concepts:

"**Whole and parts**: A great deal of experiments involved with the factors of **perception**, have put forward the very general idea that the

characteristics of the **whole** determine those of its **parts**. These **parts** lose their individuality in the **whole** unless their own properties destroy the unity of this **whole**.

"**Figure-background**: Figures are always connected to their **context**, that is the **background**... This is reflected by a number of **pattern** recognition **phenomena**, namely optical illusions" (1993, p.186).

More generally, we could speak of perceptive illusions or ambiguities (touch, hearing and other sensorial ones).

ANDREEWSKY pursues:

"**Permanence of forms properties**: certain aspects of **perception** demonstrate quite clearly the relative independence of **pattern** recognition from the conditions of **stimulation**" (p.186).

She concludes: "It is thus possible to see in Gestalt Psychology the origin to some key Systems Science concepts, such as the relation between a system and its **elements**, or the status of cognition in the **observer-observed relationship**" (Ibid).

1429

GESTALT (Dynamic)¹⁾³⁾

"A **frame of reference** that allows for **creativity** within understood **parameters**" (R. NUMMELA CAINE & G. CAINE, 1994, p.119)

These authors state that - in **knowledge** acquisition - dynamic gestalts "... contribute to a sense of **wholeness** and, at the same time, contain and permit **flexibility**, **change** and excitement".

And "These larger plots, **belief** systems and agreements are dynamic gestalts because they provide overall **patterns** that make sense. These **patterns** tie together bits and pieces of **information** and give a cohesive **meaning** and **purpose** to our daily **learning**" (1994, p.119)

Of course, dynamic gestalts imply **time binding**. (See also hereafter)

1430

GESTALT QUALITIES^{1) - 2)}

"Perceptive **structures** relating to the object perceived as a **whole**...and not deductible from the properties of the **elements** of the **object**" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.224).

The authors give as examples the **structure** of chords in music, the **structure** of melodies which is preserved intact in transposition, i.e. in changing the key. They add the following comment "...This discovery has a clear methodological significance, since it provided experimental evidence for the fundamental inadequacy of the elementalist approach even to relatively simple psychic **functions** such as **perception**" (p.234).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Perceptive Gestalten were discovered in 1890 by Ch.von EHRENFELS and taken as the base for their Gestalt psychology by M. WERTHEIMER (1923), W. KOHLER (1929) and K. KOFFKA (1935).

For a balanced critique of the Gestalt psychology, see BLAUBERG et al. (p.225-6).

The simple **lineal cause-effect analysis** is also useless to reveal global Gestalten. J.von UEXKÜLL already observed in 1928 that any Gestalt unavoidably is a result of some "Gestalt building" **process** ("Gestalt-gebend") (1928, p.183).

He clearly distinguished the spatial from the temporal dimension of the Gestalt, which makes him a forerunner of the most acute **structuralists** (p.252).

It is of paramount importance to understand Gestalten as results of our perceptive **organization**, which may be, or not, a truthful reflection of reality. In some cases, reality as perceived is a result of a specific Gestalt **shift**, as for example with the NECKER cube, that admits two different but mutually exclusive visual perceptions. Gestalten are, in any case, corner stones of the systemic viewpoint on **perception** by **observers**.

→ **Figure ground**

1431

GESTALT SHIFT ¹⁾⁵⁾

The visual perceptive jump that permits viewing in alternance two different figures within an unique ambiguous figure.

This effect can be registered for example viewing the **figure-ground** figure represented to illustrate the corresponding article.

The mutual exclusiveness of both figures shows that the **ambiguity** is in our **perception**

1432

GESTALT (TEMPORAL) ^{1) - 2)}

According to J.W. SUTHERLAND, "... the **complex system** tends to become a *temporal gestalt*, carrying on interchange with other temporal gestalts within a **field** which, itself, must be defined and treated as a gestalt rather than a **mechanism**" (1973, p.38).

This is a somewhat overstretched extension of the gestalt concepts. However, it is obvious that our **perception** of **time** depends largely upon our permanently renewed **observation** of *different* more or less stable entities, which undergo **transformations** of *different* kinds at *different* rates.

1433

GLEICHSCHALTUNG

→ **Preferences (Collective)**

1434

GLOBAL AND LOCAL ¹⁾⁴⁾

G.L. FARRE makes the following important point: "The *global* and the *local*: the first is purely conceptual, while the second is ultimately sensorial" (2000, p. 245)

He adds: "**Observation** is a mix of the two, the former being projected onto the other. There is no case where the one is got without the other in the context of the sciences of nature" (ibid)

This is significant in various way:

- the global view is always constructed. It is in fact a constructed **frame of reference**. It is thus always subject to reform and **falsifiable** in Popper's meaning
- this applies to the hypothetical general "theory of everything" as well as to the current theories about so-called **globalization** in human affairs (ecology, economy, social conditions, **cultures**)
- as different people may have quite different **mind frames**, both the global and the local view should be viewed as relative, avoiding definitive unilateral and exclusivist stances. Even the scientific history of the 19th and 20th centuries shows as much.

1435

GLOBAL VIEW ^{1) - 3)}

A satisfactory global view of a **situation** or system should take care of the following aspects:

- All the significant **elements** or **components** must be identified;
- All their important **interrelations** must be recognized;
- No spurious or fictitious **interrelations** should be introduced;
- The real **dynamics** of the various **subsystems** should be clearly characterized (i.e. **linear or nonlinear; continuous or discontinuous; cyclical** or irregular, etc.);
- The basic **interrelations** of the system with its significant **environment** must be stated;
- No imprudent or unfounded **extrapolations** should be made.

These various **rules** are qualified ("significant", "important", "spurious", "real", "basic", "imprudent", "unfounded").

This introduces the **observer's** view and implies the need for **criteria**. Moreover, such **criteria** must necessarily be:

1. based on systemic and **cybernetic models** of the **interrelations**, suitable to maintain the unity, identity and **coherence** in the representative **global model**;
2. take in account the aims of the study and the **level of observation** used.

Obviously, no valuable global view could be obtained without the collaboration and mutual **understanding** between numerous specialists through a **transdisciplinary language**.

1436

GLOBALIZATION ¹⁾⁴⁾

A **process** of **association** among different systems formerly independent from each others.

Any globalization **process** implies the following conditions:

- the different systems must become in more or less permanent contact. Such a **situation** may occur for example when systems in expansion compete for the same **resources** of **energy, matter** or **information**.
- a new **communication network** should appear among the systems, according to the new **interactions** among them.
- some **meta-regulations** or **meta-controls** should become established, subordinating the different **decisions** systems to a set of general **rules** specific to the general needs of all the interconnecting systems.

Any globalization **process** leads to a deep internal reorganization of the systems integrated into the new **whole**.

Some former **subsystems** may disappear (a recent case is the replacement of the national currencies in the European Union by the Euro). Some former **parts** of the **integrated systems** may even recover some **autonomy** in specific matters. As written by the French politologist B.de JOUVENEL many years ago: "National powers are becoming too small to handle global **issues** and are too big to manage local ones" (1974).

Also D. BELL made similar comments.

1437

GLUE ¹⁾⁴⁾

A general **metaphor** covering "a range of related verbs such as adhere, attach, bind, bond, cohere, combine, connect, fuse, join, liase, link, paste, tie and weld" (R. Paton, 1999, p. 153)

These verbs describe various types of **interrelations** in more or less integrated or loose systems.

All describe **processes** with their corresponding **flows** of materials and **informations**.

"Glue" is apt as a metaphor because while the flows among **elements** are either permanent or intermittent, or **recursive**, they imply specific **interactions**.

Strongly organized systems are those very strongly "glued", as for example living beings wherein the **parts** cannot remain functional in their own way when cut out of the system.

Social systems or computer **networks**, for instance, are less strongly "glued" as their parts can somehow maintain their own functionality when separated.

In this paper Paton describes a variety of glues corresponding to different **contexts** and **functions**. He explores the relations of the concept with those of **pattern**, **limit** and co-limit and its more general meaning in **categorical** terms.

He also observes that glue relations can be **binary** or multiple in relation to a single element. There may thus be distinct modes of adhesion, attachment, etc.

(This is already clear at the chemical level for instance)

1438

GOAL¹⁾

"Some end **state** to which a system tends by virtue of its **structural organization**" (A. RAPOPORT, 1966, p.8).

A goal is generally understood as the **purpose** toward which an endeavor is directed, or an objective. R.L. ACKOFF for example states: "The goal of a **purposeful system** in a particular **situation** is a preferred outcome that can be obtained within a specified **time period**" (1972).

It has also the connotation of "blank" or "target".

This makes the concept ambiguous from the systemic viewpoint, because it is thus more or less implicitly surmised that the **entity** or system is conscious and volitive, which may very well introduce excessively anthropomorphic biases in any research about non-human as well as **human systems** (individual or social).

Even a keyed-down formulation as for example speaking about the final **situation** toward which the system tends, does not solve the difficulty, because "tends" seems still to imply voluntary **activity**. A good example could be what FREUD called "death wish". Every **living system** is somehow "death directed". This final and unavoidable **state** seems even to be inscribed in it since its beginnings, by way of the **2d principle of thermodynamics**, which impedes the very long term **maintenance** of **heterogeneous organization**.

However, **living systems** seem to pursue goals precisely in the opposite sense: their functional workings lead (aim?) to the **maintenance** of their **organization**. So, what?

Until now, nobody seems to have found any satisfactory term to replace "goal", that would solve these semantic difficulties. Let us thus remember to be very careful when using the word.

For the time being, RAPOPORT's definition is still the most honest, semantically speaking.

1439

GOAL COMPLEX^{1) - 4)}

A **hierarchical** ordering of the goals and sub-goals of a system (according to D.M. Mc KAY, 1969, p.112).

Complex systems are necessarily **hierarchized** because their global goal and principal subsidiary goals can be reached only through the orderly attainment of a number of lesser previous subgoals.

For example, to go out, I must first open the door. To open the door, I must first handle the knob. Therefore I must first move my arm and my hand, etc.

The correct ordering of a proper sequence of subgoals is an unavoidable need in order to reach a specified goal. Therefore, each and every **subsystem** concerned must function correctly at the precise instant.

→ **Priority of the simple**

1440

GOAL-DIRECTNESS¹⁾

A seemingly purposive and specific **activity** in a **living system**.

According to G. SOMMERHOFF: "The most distinctive character of the **behavior** of higher **organisms** is its goal-directness, its apparent purposiveness. In fact, it is largely through this apparently **teleological** nature of their **activities** that living **organisms** betray their exceptional **organization**. And their position on the "scale of life" is largely determined by the degree to which they possess these characteristics" (1969, p.148).

He further adds: "Many animal **activities** are patently goal-directed in a way which makes it clear that we are dealing here with an objective system-property – a property, moreover, which we can assume to be compatible with the basic laws of physics and chemistry. We can assume this because we know of **servo-mechanisms** and **automata** that are capable of essentially similar types of **behavior**" (p.149).

Orientation toward a goal, as a manifest tendency, seems to be a result of the growing **perception** of the **time-dimension** by evermore differentiated and complex **brains** throughout biological **evolution**. The most essential aspects of this are the capacity to memorize and the ability to figure out a growing number of possible future **situations**.

On this topic, SOMMERHOFF states: "The ordering **relations** here are in **time** as well as in **space**" (p.150) and... "The central nervous system more than any other part of higher **organisms** is responsible for introducing **teleological order** into the **activities** of the system" (p.151).

In this same paper SOMMERHOFF introduces the concept of **directive correlation** which eliminates the *finalist taint* of the goal-directness **concept**.

1441

GOAL SEEKING^{1) - 3) - 4)}

A characteristic of a system which directs itself toward the achievement of a goal.

This is a concept in need of a close scrutiny.

First of all, we should carefully distinguish what the system does from what we consider that it is doing.

The most general, and possibly the only really basic, "goal" of any system is its own perpetuation. We should here avoid the term "survival", because it would restrict the **concept** to the **living systems**. However, has any non-living system a "goal"? Does a galaxy have a goal, even if it seems to be self-perpetuating for eons? Does a crystal have a goal? Does a planet have a goal? Has **GAIA** a goal?

Really, proper goal seeking is probably restricted to living beings. But even then, in which sense could a bacteria or a virus have a goal? And when do goals appear: with **cells**?, with worms?, with vertebrates?, with mammals?, with apes?, with men?

And another tricky problem appears: do societies, species or **ecosystems** – which are not strongly **integrated systems** – have "goals"? Can they be "goal-seeking"?

As to our role as **observers**, we obviously attribute goals to many systems by **analogy** with our own goal seeking manner, and we frequently colour this concept with a shade of **free will**.

To become "goal seeking", even in the restricted sense of "survival seeking", a system must be **autonomous** (i.e. be **self-determined** in VENDRYES' sense) or **autopoietic** (i.e. able to maintain its **identity** by **recursive organizational closure**, in VARELA's sense).

To summarize, the **semantic** status of the **concept** is shaky.

For ACKOFF's views on the topic, see **System (Goal seeking)**

1442

GOALS CONFLICT^{1) - 4)}

A strong opposition or even incompatibility between the goals of distinct systems.

As D. Mac KAY explains, goals conflicts may arise between two (or more) systems "with incompatible goal-settings, and a common **field** of **operations**. In the ordinary way, each is bound to be driven by its (own) **feedback signal** to run eventually "flat out" in opposition to the other".

"How could this absurd and wasteful **situation** be resolved, or prevented from arising? In the absence of a third party, we must imagine one or both systems to possess some kind of an additional **effector**-system, capable of physical **action** upon the **environment**, to be brought in automatically when goal-conflict arises. The simplest one might be a destructive device of some sort deployed (presumably by each "side") with the sub-goal of cutting the power to the other, or otherwise put it out of **action**. Given a **situation** not too symmetrical, one system could then emerge triumphant and its primary goal would be attainable.

"Suppose however, that by **chance** or by **design**, the physical **activity** of one (or both) succeeded in altering the goal-setting of the other. Displaced in one direction, it would of course

make matters worse, but if instead the displacement brought the two goal-settings together, then we would have the beginnings of a wholly different kind of "resolution". Instead of being rivals, the two systems could evidently become partners, sharing the effort of furthering the common goal. The closer the approximation of their respective settings, the greater the economy of total effort" (1969, p.115).

Such a viewpoint is obviously of utmost importance for the resolution of conflict in general and, specially between social groups or systems. The setting of any reciprocal **regulator**, whose work must be paid for, entails a **cost**, but most generally results much less costly than the mutual damage resulting from open and unresolved conflict.

1443

GOALS (Hierarchies of) ^{1) - 2)}

The regulating or controlling arrangement of main and subordinate goals at different **levels**.

G. SOMMERHOFF writes: "Frequently, indeed almost invariably, various different forms of **goal-directness** or directiveness are all present and intimately interrelated in the same biological **situation**. This is a common source of confusion. In particular, one of the most distinctive characteristics of the living **organism** is the hierarchical manner in which the goals of various part-activities (or **activities** of its **parts**) are interrelated and integrated. In a typical case each **part activity** has a proximate and transient goal, which is itself subservient to the less transient and less proximate goal of the **action** as a whole, which in turn is subservient to the goal of the **behavior patterns** as such, and so on. Or it maybe the goal of one **activity** to establish or maintain the conditions under which another **goal-directed activity** can properly take its course while another **activity** in turn establishes or maintain the prerequisites for the first, etc... all of this involving **structures** and **mechanisms** which are themselves the product of directive developments. There is nothing to parallel this co-ordination and **integration** in the world of **machines** and **automation**" (1969, p.150).

As to this last statement, it should be taken into account that it has been pronounced in 1969.

Goal degradation, i.e. the provisional or definitive giving up of higher **level** goals in systems struggling for **survival** is a significant aspect of the **General Adaptation Syndrome**. It seems to correspond to a return to the "basics", as stated by L. SKYTTNER, in relation to the "bottom of pyramid of needs, the reptilian brain" (1992, p.5).

To resume, goals are hierarchized in **space** and **time**. This corresponds to the fact that **living systems** do maintain a transforming **coherence** in **time** (by **morphogenesis**, **structuration** and a tendency to **dynamic stability**).

→ **Priority of the simple**

1444

GOALS (Space of) ²⁾

The partly ordered **set** of the successive goals of a system.

A. LOCKER et al described the goals **structure** of a **teleogenic** system. Their **model** is a **lattice**. When this **lattice** is **embedded** in a more adequate and complete one, it becomes possible to study the way newer goals are searched for (1975, p.27).

1445

GOALS (Variable) ²⁾

The different but compatible goals that coexist and generally enhance each other in a complex system.

Variable goals are a characteristic of complex systems, which are not confined to the sequence **stimulus-response**, nor even to some **binary** or dichotomous **control**.

The **autonomous complex system**, being **equifinal**, is able to chose among a number of possible intermediate goals the one that best suits its global **stability**, and becomes a kind of superseding general goal, acting as a **selector** of convenient intermediate ones.

1446

GOALS WITHIN GOALS ¹⁾

I. BLAUBERG et al., develop an idea akin to SOMMERHOFF's one in the following terms: "The adequate specification of the goals of a given system **organization** requires the preliminary determination of the goals of a larger system which includes the given one. This is a necessary condition for determining the real **functions** of a given system within a certain larger **whole**; this **functions** and thus the goals of a given system are obtained from an analysis of a certain **set** of mutually dependent **functions** and goals of a larger system..." (1977, p.277).

In HEGEL's terms, who of the master and the slave is, in the end, the master? It would seem, in view of the obvious **interdependence**, no one... or both.

1447

GOAL-SEEKING SYSTEM ^{1) - 3)}

W. R. ASHBY writes: "Every **stable system** has the property that if displaced from a **state of equilibrium** and released, the subsequent movement is so matched to the initial displacement that the system is brought back to the

state of equilibrium. A **variety** of **disturbances** will therefore evoke a **variety** of matched reactions.

"This pairing of the line of return to the initial displacement has sometimes been regarded as "intelligent" and peculiar to living things. But a simple refutation is given by the ordinary pendulum: if we displace it to the right, it develops a force which tends to move it to the left; and if we displace it to the left, it develops a force which tends to move it to the right. Noticing that the pendulum reacted with forces which though varied in direction always pointed towards the centre, the mediaeval scientist would have said "the pendulum seeks the centre". By this phrase he would have recognised that the **behaviour** of a **stable system** may be described as "goal seeking". Without introducing any metaphysical implications we may recognise that this type of behaviour does occur in the **stable dynamic systems**" (1960, p.54).

→ **"LE CHATELIER Principle"**.

As human systems (personal and social) describe their goals and pursue them in a willful way (i.e. an at least seemingly not rigorously pre-determined way), one may wonder if the words "goal-seeking" should be used for all types of systems.

Even a biological system as an animal, which exhibits many kinds of complex **activities** is not simply responding passively to a **stimulus**, which is the case with the pendulum.

In any case, a true goal-seeking seems to necessarily imply corrective **feedback**.

ASHBY himself states: "**machines** with **feedback** are not subject to the oft-repeated dictum that **machines** must act blindly and cannot correct their errors" (p.55) and moreover: "A system which possesses **feedback** is usually actively **stable** or actively **unstable**; and whether it is **stable** or **unstable** depends on the quantitative details of the particular arrangement" (p.54).

1448

GÖDEL'S INCOMPLETENESS THEOREM ^{2) - 3)}

Formal logic version: "For every consistent formalization of arithmetic, there exist arithmetic truths unprovable within that formal system".
Complexity version: "There exist numbers having complexity greater than any theory of mathematics can prove".

Both version are given by J. CASTI (1994, p.139/146).

At the beginning, the theorem seemed to be merely a formal logical one about arithmetic truth, in correspondance with the formal logic version.

Various different versions have appeared through time, and slowly, it dawned that "... we'll never get at all the truth by following **rules**; there is always something out there in the real world that resists being fenced in by a deductive argument" (p.150).

G. CHAITIN has been one who most insistently inquired into the matter.

"If a theorem contains more **information** than a given **set** of axioms, then it is impossible for the theorem to be derived from those axioms" (Cited by Joseph FORD, 1989, p.609)

"...in a **random** sequence each sequential digit carries positive **information** since it cannot be predicted from **knowledge** of its predecessors. In consequence an infinite **random** sequence contains more **information** than all our finite human logical systems combined, hence, verifying its **randomness** lies beyond constructive proof" (Ibid).

"...in all truth, GÖDEL permeates the physical world even more than he does the mathematical. Indeed we now have no choice; we must come to grips with GÖDEL, with the paradox of solving the unsolvable, predicting the **unpredictable**" (Ibid).

(as stated by F. HEYLIGHEN)

"...in each formal system (containing the axioms of number theory) there exist propositions such that it is impossible to distinguish between the **truth** (probability) and falsity of the proposition within the system itself" (1990a, p.441).

Although this seems a purely negative statement, it "can also be interpreted in a positive way by moving to a higher **level of representation**, where (it) expresses a certain high-order **closure**.

"The theorem of GÖDEL is proven by means of a construction allowing the formal system to represent propositions of the system by numbers so that it is possible to interpret propositions about numbers to be propositions about propositions of the same system. This **self-reference** is an example of cyclical **closure**. The incompleteness result can be understood as an application of the more general principle of the impossibility of complete **self-reference** (LÖFGREN)" (p.441).

GÖDEL's theorem is related to A. CHURCH's work. As stated by R. SCHOENFELD: "CHURCH's thesis (is) that decidability is equivalent to **recursiveness**, which is equivalent to computability" (1994, p.88).

The practical systemic meaning of GÖDEL's incompleteness theorem is thus resumed by J. CASTI: "A universal feature of **knowledge** is that one must get outside of a system in order to really understand it" (1994, p.17).

1449

GOLDEN PROPORTION ^{2) - 4)}

The **limit** to which tends the ratio of two successive numbers of the **FIBONACCI series**.

The value of the golden proportion (or section) is

$$\frac{(\sqrt{5}-1)}{2} = 0,618$$

It has been considered since Antiquity as reflecting the basic harmonies of nature. A specific angle, the Golden section, i.e. 137°30' corresponds to the Golden proportion.

The so-called and related Golden number is the limit of the series 1/1, 1/2, 2/3, 3/5, 5/8, 8/13, etc., i.e. again:

$$\frac{(\sqrt{5}-1)}{2} = 0,618$$

From the systemic viewpoint it corresponds to the **cyclical organization** of material **structures**, as a result of reciprocal influence of **fields** of forces. It tends to produce **helical** orderings of **elements**. It reflects the relation between **parts** and **whole** in progressive construction. It also seems related to the **fractalization process**. It can be encountered in many natural systems. See, for ex. St. DOUADY and Y. COUDER's study on vegetal spirals (1993, p.26-35).

The Russian sociologist A.A. DAVYDOV has researched in the recent years the role of the golden proportion in social systems (1992, p.19-25).

1450

GOVERNABILITY ⁴⁾

The supposed or real possibility to govern systems.

In any case, governability is at best a limited possibility. R. VALLÉE observes: "The governability problem is the steering problem: A **dynamic system** is perfectly governable if, whatever the initial instant and initial **state**, and whatever the final instant and final **state**, it is possible to find an **input function (command)** that, applied from the initial to the final instant, gives the possibility to lead the system from the initial to the final **state**".

VALLÉE is however somewhat skeptical: "There is a certain mathematical **duality** between **observability** and governability and it is obvious that a system cannot be totally governable, just the same as it cannot be completely observed" (1995, p.23).

Governability therefore, is not much more than hypothetical wishful thinking, even in **human systems**. Within the **limits** of a more or less **metaphorical** comparison, insect societies appear to be **self-steered**, i.e. their members automatically create a global **order** through their **interactions** and, at the same time, become submitted to it. Could human societies really be "governable" in a different and more volitive sense?

→ "**stigmergy**".

In insect societies, global **reliability** is obtained, just like in a **von NEUMANN automaton**, notwithstanding the possible poor quality of some **components**.

If human **sociosystems** are self-governed, or **self-steered** in the same way, the nature, **goals** and achievements of politics in its most general and **purposeful** sense become very difficult to assess.

Finally, governability is in most cases an illusion. In St. BEER words, who had much practical experience of such **situations**: "A minister can always call for an elaborately reorganized **set of data**, on which complicated mathematics have been done; but it is the computer that generates the **variety**, and not the real world This is quite fundamental nonsense" (1974, p.40)".

1451

GOVERNANCE ²⁾

The **process** of directing a system towards some pre-defined **goal**.

In G.G. JAROS words: "Governance rests on the application of **feedback** and **feedforward** which ensure that the **teleos** (i.e. "**goal**" in JAROS terminology) is reached" (1994, p.5).

As most of the systems to be governed are complex and **nonlinear**, governance should not be taken as a simple (nor even complicated) **deterministic** procedure. **Feedback** and **feed-forward** may very well in some cases fall wide off the mark.

1452

GOVERNANCE (WORLD)

→ **World Governance**

1453

GOVERNOR ^{2) - 4)}

Any internal device that is supposed to **control** a system or a **subsystem**.

G. BATESON considers this term to be a misnomer and states: "... no **part** of ...an internally interactive system can have unilateral **control** over the remainder or over any **part**... Even in very simple corrective systems, this **holistic** character is evident... The governor is, essentially, a sense organ or **transducer** which receives a transform of the **difference** between the actual running speed of the engine and some ideal or preferred speed... The **behavior** of the governor is determined in other words, by the **behavior** of the other **parts** of the system, and indirectly by its own **behavior** at a previous **time**" (1973, p.286).

This semantic muddle is responsible for:

- 1) the misunderstandings about the concept of **control** (see "**control of and control for**");
- 2) the negative fame earned by **mechanistic cybernetics** with psychologists and social scientists, who fear possible psychic and social abuse by self-styled would be "**controllers**".

1454

GOVERNOR MECHANISM (Virtual)¹⁾²⁾⁴⁾⁵⁾

A complex **control** in a **network** obtained through reciprocal compensation among a **set** of oscillating **elements**.

Such a mechanism is described by P. Smith CHURCHLAND, who gives the example of a set of electrical generators, each of them presenting "**fluctuations of frequency** of 10% around some average value"(1989, p. 365)

"Taken joined together in a suitable network, their collective frequency **variability** is only a fraction of that figure because, statistically, generators momentarily fluctuating behind the average **output in phase** are compensated for by the remaining generators, and conversely, generators momentarily ahead in phase have their **energy** absorbed by the remainder. The entire system functions from an **input/output** point of view, as a single generator with greatly increased frequency **reliability**, or as control engineers express it, with a single, more powerful, "virtual governor"(Ibid)

This example underline a basic characteristic of networks: Their **efficiency** as a **whole** makes them advantageous as a whole, but also for every participant. This explains how and why networks are the typical device for any kind of social **organization**.

→ **Automata (Reliability of); Co-evolution; Correlation device; Correlation (Directive); Feedback (self-normative); Oscillator; Regulator; Reliability in dynamic terms; Sociality; Socialization**

1455

GRADIENT^{1) - 2)}

Difference between some energetic or material **level** existing between a system and its **environment** or within **subsystems** of the same system.

Such differences normally produce **flows** which may disappear progressively through a diffusion **process**.

Gradients are at the same time a condition and a manifestation of a system's **heterogeneity** (or **organization**) and a condition of the existence of the system within its **environment**.

Their decrease implies an increase of **entropy**.

Every gradient is linked with a corresponding **flow**, which is termed "conjugated **flow**".

R. THOM observes that, while gradients are quantitative, they offer also various qualitative aspects (1991, p.107). These result partly from their **interactions**.

An example can be the "**conflict** between horizontal polarity and vertical direction, which are dual in our **space**" (p.112).

Thom also explains that **attractors** correspond to maxima in gradients (p.161).

1456

GRAMMAR¹⁾

"A **set of rules**" (R. ROSEN, 1972, p.63).

This term, introduced in this sense by ROSEN, is useful, as it conveys in a kind of short-hand a **meaning** of interconnected globality.

A grammar prescribes a **combinatorics** stating admitted **congruences**, and defines **constraints** in any **communication language**.

1457

GRAMMAR (Generative)¹⁾⁵⁾

"The **brain programs** that are followed in generating the sentences in a **language**" (J.Z. YOUNG, 1978, p.293)

Young explains: "A set of phrase **structure programs** provides the deep structure, and transformational programs generate various surface structures"

He gives as an example: "Cows eat grass", "Grass is eaten by cows" or "Can cows eat grass?" (Ibid).

1458

GRAMMAR (Universal)¹⁾³⁾⁵⁾

The **set of rules of languages** construction that are common to all **languages**

This concept has been introduced by N. CHOMSKY and its validity is today generally admitted. Grammar in this sense includes:

- phonetic **rules**, which define the ways sounds are produced
- **morphological rules**, which define the ways words are constructed from sounds
- **semantic rules**, referred to the **organization** of the system of **meanings**

However, as commented by EDELMAN, any specific **language** must be learned, i.e. any **language** act is intersubjective, occurring between at least two individuals. Moreover it is also learned within a specific **culture**, which historically defined the **symbols** used (1992, critical postface).

→ **Learning matrixes (Steinbuch's)**

1459

GRAMMAR¹⁾³⁾⁵⁾

"The set of **brain programs** by which sentences are generated" (J.Z. YOUNG, 1978, p. 293).

Such programs, whose **description** and even nature are still quite far to be completely understood, are related to at least three aspects of natural **languages**: the formation of **phonemes** (elemental sounds), of morphemes (words) and the **rules** for the construction of sentences.

The construction of **meanings** seems to be still at a fourth **level**, since it is perfectly possible to construct apparently well structured sentences, devoid however from any meaning, as for ex. "Ospakat waza umbin sra dnefgo"(w-hich has no sense at all) , or the following:

"Mutoto alivunja sahani moya", which is significant in Kiswahili... if your brain did assimilate the **meaning code** corresponding to that language.

1460

GRAND ENSEMBLE^{1) - 2)}

A totally interconnected **network**.

St. KAUFFMAN, who introduces this type of **networks**, writes: "Since each **element** receives an **input** from all other **elements**, there is only one possible wiring diagram... this ensemble corresponds to the largest possible ensemble of **Boolean networks** of **N variables**" (1993, p.192).

He also states: "The Grand Ensemble is maximally disordered" (p.472), and, as a result, its **behavior** is **chaotic** (Ibid).

It is interesting to observe that a type of maximal **disorder** corresponds to the maximum number of **constraints** in what ASHBY calls "**richly joined systems**". The most useful or creative systems are thus those that are moderately constrained, admitting sufficient leeway for **adaptations**.

1461

GRAPH GRAMMAR²⁾⁵⁾

D. GERNERT proposed graph grammar as follows: "A mathematical technique which supports characteristic operations including the generation, transfer, **recognition**, interpretation and application of **patterns**" (1997, p. 179)

Moreover "...**parallel processes** can be described by parallel graph grammars"(Ibid)

Gernert characterizes the basic patterns:
Pattern generation: the building up of a greater unit, not from **elements**, but from already existing building blocks

Pattern transfer: the duplication and insertion in different **locations** of an already existing pattern

Pattern recognition: an act of classification where a **classification** scheme has been previously defined

Pattern interpretation: an interpretation **process** of an existing pattern in a system that can influence the system's development

Pattern application: the triggering of a **change of state** by the transfer of a pattern to another location

As patterns are **interrelations**, it is possible to represent them by graphs. Complex graphs can be constructed step by step, using a "cellular graph automaton", i.e. "an underlying graph where in each **vertex** an **automaton** equipped with an **algorithm** is installed"

see figure next page

Figure: see entry **Graph Grammar**

The fig. is from GERNERT, Dieter:

"Graph grammar as analytical tool in physics and biology" – Biosystems 43, 1997.

Gernert gives an overview of the field (opened up by K. Zuse in 1975) which is developing steadily in theory and through applications in physics and biology.

→ **Artificial life; Game of life; Graph theory; Graph (transformation); Hora and Tempus parable; Hypercube; Network; Transfer function**

1462

GRAPH GRAMMAR (Sequential) ²⁾⁵⁾

D. GERNERT explains how graphs can be re-written, thus generating a sequential graph grammar through **embedding rules**. He describes as follows some important properties of this type of representation graphs:

1. The new graph generated by a production rule can be "more complex" or "less complex" than the old one
2. The continuation of the rewriting process is not necessarily unique: there may be non-determinism as well as determinism, or a combination of both, depending on the features of the individual graph grammar
3. There may be different sequences of derivation steps which lead to the same result, the "genesis" of a graph is not necessarily unique
4. A sequence of derivation steps can lead to the start graph again: "periodic graph grammars" are possible
5. In degenerate cases it may happen that none of the production rules are applicable so that the procedure stops

→ **Graph (Parallel rewriting of a); Rewriting**

1463

GRAPH (Group of a) ²⁾

"The collection of all its automorphisms" (F. HARARY, 1967, p.25).

Different graphs can be topologically **isomorphic**, and thus reunited through a **group**.

F. HARARY writes: "It is a permutation **group** acting on the **set** of points (**nodes**). It is known (FRUCHT, 1949) that every finite **group** is abstractly **isomorphic** to the **group** of some graph" (Ibid).

This author also defines the **line (edge) group of a graph**: "The permutation **group** whose **objects** are the lines of G and whose permutations are induced by those of the **group of automorphisms**" (Ibid).

A transformation graph.

From P. DELATTRE: 1974, p. 106

1464

GRAPH of a FUNCTIONAL NET ²⁾

Any **oriented graph** used to represent the multiple **interconnexions** in a complex **function** in a biological **organism** or a human **organization**.

N. RASHEVSKY showed how to establish graphs of this type. Such graphs correspond to a very general type and can be used as **isomorphic functional models** of numerous and very different **classes** of systems. RASHEVSKY gave many examples in his paper and, moreover, showed how to interconnect various partial graphs which represent different specific as-

pects of a complex systemic **function**. (1956, p.126-34; also 1960, p.345-70).

St. BEER states: "The **vertices** of a graph are regarded as **elements** of a **set** which is mapped into itself, of which **set** the graph is then a multi-valued **function**" (1968, p.218).

1465

GRAPH (Parallel rewriting of a) ²⁾

A. LINDENMAYER and K. CULIK II state that, when we plan to describe a system throughout an extended period of **time**: "... we have to introduce **rules** by which a new graph can be produced from a previous one. Using such a system of **rules**, one obtains either a sequence of graphs (in their order of development), or a **set** of graphs (without an ordering)...

"A parallel graph rewriting system in our sense consists of a set of **node labels**, a set of **production rules**, a set of **connection rules**, and a starting graph" (1979, p.46).

This introduces **transformation graphs**.

1466

GRAPH THEORY ²⁾

A branch of mathematics dealing with the properties of the **links** between points or **nodes** in a **network**.

Graph theory, introduced by D. KÖNIG in 1936, is practically a formalized taxonomy in qualitative mathematical terms of the multiple possible types of **interconnections** between discrete **elements**.

There is a close relation between graphs and **matrixes**: A graph can be represented by a **matrix**, and vice-versa.

H. ATLAN writes: "The interest of graphs is that they do not only produce a pictorial **representation**, but that moreover their logical properties allow for an **algorithmic** writing – i.e. automatic – of the **state** equations of a system".

D. GERNERT even proposes a "graph **grammar**" as "a formalism which allows the derivation of a new graph from an old one by a sequence of consecutive derivation steps" by the use of "graph **rewriting** systems" (1989, p.66).

According to A. KAUFMANN, graph theory is "... that field of **set theory** concerned with the **binary relations** of a **set** with itself, admitting that the **set** is countable. This theory is not autonomous in relation to the other developments of the **set theory**, but it possesses a specific vocabulary, very extensive and specialized, it opens a very large field of applications in physics, in economy, in psychology, in telecommunications, in organic chemistry, in **organizations**, in certain artistic domains, etc..." (1970, p.1).

As such, it is undoubtedly a quite basic tool for general system **modeling** and deserves in itself a complete study. Hereafter, a host of co-ordinated – and, as far as possible, standardized – definitions are given, with short comments. This material is essentially based on references from F. HARARY (1967), P.W. KAS-TELEYN (1967), A. KAUFMANN (1970), G. KREWERAS (1972), S. LIPSCHUTZ (1976) and A. SACHE (1974). Generally no precise references are given hereafter, as the following is a blended synthesis of these authors views.

According to the general character of graphs, few references are made to any specific properties in particular disciplines.

Definitions given correspond to 2-dimensional **representations**. It is however possible, although much more difficult, to conceive 3-, 4- or n-dimensional **representations**, as for example the 4-dimensional **hypercube** with 16 **nodes**, which can be associated, for instance, with **time** sequences along connecting **edges**. see figure page 174

To begin with, F. HARARY observes the rampant terminologic confusion that affects the field and establishes the following equivalences (1967, p.4):

"point _ vertex _ node _ junction _ 0-simplex
 "line _ edge _ arc _ branch _ 1-simplex
 "cycle _ circuit _ elementary cycle _ circuit path _ polygon
 "path _ arc _ elementary path _ simple path _ chain

We have selected the underlined terms, but this is merely a more or less arbitrary decision, based on the necessity to avoid ambiguities. We would not dream to add still more confusion, but had it not been nice to call "arrow" (used by St. KAUFFMAN, 1993), the *oriented edge* ? We start thus with these four basic definitions:

NODE: A discrete element in a graph

EDGE: A direct connection between two nodes

ARC: An oriented edge between two nodes.

POLYGON: A closed succession of arcs such as the last node is the same as the first one.

The principal types of graphs are:

DIGRAPH, or directed graph, which consists of:

- a set of elements (nodes)
- a set of arcs (directed edges). The arcs define relations, sometimes also called "influences".

Digraphs can be *labeled*, i.e. affected with some kind of data. "Such graphs are frequently used to picture dynamic **situations**" (LIPSCHUTZ, 1976, p.119).

A digraph "is *strongly connected* or *strong* if each point (**node**) is reachable from each other point (**node**)...(it) is *unilaterally connected* or *unilateral* if, for any two points (**nodes**), at least one is reachable from the other...(it) is *weakly connected*, or *weak* if, for any division of its set

of points (**nodes**) into two non-empty subsets, there is a line (**edge**) from a point (**node**) of one subset to a point (**node**) of the other" (HARARY, 1967, p.18).

Finally, it is *disconnected* if at least one node cannot be reached from any other.

"A **source** (**root**) of a digraph is a point (**node**) from which all other points (**nodes**) are reachable" (Ibid).

In this sense, a source or **root** is the inverse equivalent of a **sink**.

J. WARFIELD advocates extensive use of digraphs to map **structural models** of complex systems as a way to what he calls "Interpretive Structural Modeling" (1989b, Chapter 10).

He writes: "A graphically integrated language offers advantages in representing complexity. Such a language can have well-defined graphic symbols, and layers of representation of differing sophistications" (1995,e). **TREE**: "A finite connected graph with no cycles (**polygons**)" (LIPSCHUTZ, 1976, p.87).

"The tree consisting of a single vertex (**node**) with no edges is called the *degenerate tree*" (Ibid, p.105).

A tree starts from a **root R**, i.e. a **node** which does not receive any **arc**. Any other **node** in the tree receives only one **arc**. The tree may bifurcate at any successive **node**, including A and these **bifurcations** can be multiple (A. KAUFMANN, 1970, p.90).

As a result, there is a unique **path** from R to any **node** in the tree and the length of the **path** from R to any **node N** is made of n arcs, whose number characterizes the *depth* of N.

The end **node** in any **path** is called a **leaf** and the **path** from the **root** to a **leaf** is a **branch**.

Trees are very useful for the description of hierarchical organizations.

A **MULTIGRAPH** is a graph containing multiple edges connecting the same nodes and specially, loops, which are edges whose end node is the original node itself. According to S. LIPSCHUTZ: "The definition of a graph does not permit such multiple edges or loops. In other words, we may define a graph to be a multigraph without multiple edges of loops" (1976, p.82).

Furthermore: "A multigraph is said to be finite if it has a finite number of vertices (**nodes**) and a finite number of edges" (Ibid., p.83).

A **SUBGRAPH** of a graph is a distinguishable part of the graph which is itself a graph. A good example is the set of the local roads on a map giving also the national roads. A subgraph may be or not be connected to the general graph. Subgraphs are generally more strongly and specifically connected than the graph as a whole.

Numerous types of more specific graphs have been defined, as for instance:

- The **acyclic graph**, which has no **cycle** (**polygon**): "A finite connected graph with no cycles is called a **tree**" (LIPSCHUTZ, 1976, p.87).
- The **anti-symmetric graph**, in which the nodes may be connected by uni-directional arcs only. Examples are a genealogical tree, or the military hierarchical command order
- The **bipartite graph**, whose edges can be partitioned into two complementary subgraphs in such a way that each node of one subgraph is connected at least to a node of the other.
- The **complementary graph** which, by combination with another graph, constitutes a complete graph.
- The **complete graph** of which any node is connected to every other node. If the connections are merely edges, the graph represents a **structure**. It can be dynamized by the replacement of the edges by arcs.
- The **connected graph** in which there is always at least one path between any two nodes. However, even a unconnected graph may contain connected subgraphs.
- The **strongly connected graph** would be, after KAUFMANN, the central subgraph within a graph, in which all possible arcs between all nodes do exist.
- The **Eulerian graph** in which there is which there is a complete trail (walk) traversing the whole graph by a non-repetitive succession of edges or arcs. The typical non-Eulerian graph is the famous Koenigsberg bridges example studied by EULER (1736) and showing that no possible totally non-repetitive trail did exists for crossing the seven city's bridges once only in the same walk.
- The **full graph** is that one wherein all nodes are reciprocally connected one to one by two arcs of opposite direction (KAUFMANN, 1970, p.16).
- The **Hamiltonian graph** is the graph in which a closed walk includes every node once and only once.
- The **labeled graph** in which "...edges and/or vertices (nodes) are assigned data of one kind or another" (LIPSCHUTZ, 1976, p.89).
- The **non-polygonal graph** in which there is no closed route between nodes. If such a graph is connected by arcs and if there is a circulation of flows entering by one node only, the graph becomes more or less definitively disconnected if the flow is interrupted, even briefly.
- The **oriented graph** whose all edges are arcs.
- The **random isotropic directed graph** in which an increasing number of randomly introduced oriented edges (arrows) lead to critical thresholds at which the con-

nectivity properties change abruptly (St. KAUFFMAN, 1993, p.423). The condition is that the ratio of the number of arrows to the number of **nodes** must surpass a certain limit.

- The **symmetric graph** in which each **arc** joining one **node** A with another **node** B is complemented by a reciprocal **arc** BA.

Graphs of different **networks** can be compared.

Isomorphic graphs "can be represented by the same abstract graph... if there is a one to one correspondence between their **elements** which preserves the incidence relation" (KASTELEYN, 1967, p.50).

Homeomorphic graphs are merely **isomorphic** in relation to some specific property of their **structure**. A square is **homeomorphic** to a diamond or a rectangle.

These different types of graphs can be used for different **network situations**.

Hereafter, some more definitions related to graph theory are given (or repeated).

BRANCH: In a **tree**, the **path** from the **root** to a **leaf**.

CHAIN: A continuous sequence of **arcs**.

CIRCUMFERENCE: The length of the longest **polygon** (or **cycle**).

CUT POINT (or OUTPOINT): In a **connected graph**, any point (**node**) whose removal results in a disconnected graph.

FOREST: A graph with no **polygons**, i.e. whose all **subgraphs** are **trees** with interconnected **roots**.

GIRTH: The length of the shortest possible **polygon** (In J. WARFIELD 1989b, p.338: **geodetic cycle**).

HEAD: In an **oriented graph**, the first **node** in a **chain**

LOOP: An **edge** or **arc** whose origin and extremity coincide

MATRIX (Connection): The matrix which represents in a **binary** numerical form the **edges** or **arcs** and the connected **nodes**

NODE (Unreachable): A node not connected by any **edge** or **arc**. LIPSCHUTZ calls it an "isolated vertex".

NODE (Degree of a): The number of **edges** that are incident on it. This is the sum of the number of incoming and outgoing **edges**. BRYANT calls it the "valency" of the node

NODES (Distance between): The total length of the shortest **path** connecting them.

PATH: A **walk** with distinct **edges**. A path is simple if it does not use twice the same **edge**. It is elemental if it does not use twice the same **node** (Hamiltonian path).

ROOT: A **node** from which all other **nodes** can be reached. HARARY calls it "source". In a **tree** the root emits but does not receive.

SINK: A **node** which receives but does not emit, i.e. the opposite of a **root**.

TAIL: In an **oriented graph**, the last **node** in a **chain**.

TRAIL: A **walk** with distinct **arcs** (Eulerian trail).

WALK: According to LIPSCHUTZ: "... an alternating sequence of vertices (**nodes**) and **edges**... The number of **edges** is called the length of the walk" (p.83).

WALK (Self-avoiding): A walk in which all **nodes** are distinct, with the possible exception of the first and the last ones (KASTELEYN, p.51).

WALK (Spanning): A walk which "... contains all the vertices (**nodes**) of the **digraph** (Ibid., p.120).

WALK (Steps of a): The **edges** included in the walk. (Ibid, p.51).

A last mention should refer to the **P.E.R.T.** (- **Process** Evaluation and Review Tasks", a method to rationally order subtasks in a complex project. A **P.E.R.T model** is a graph extended into the **time** dimension, in which the shortest possible **temporal path** is sought by an optimal ordering of tasks.

1467

GRAPH (Transformation)²⁾

A graph that represents all the possible **states** of a system and all the possible **transitions** from one **state** to another.

This **model** was proposed and widely developed by P. DELATTRE and used by him in radiobiology and radiotherapy. (1974). It can however be used for the **representation** of **transitions** from **state** to **state** in any kind of **complex systems**.

1468

GREY BOX²⁾

A kind of **black box** which is known to contain some internal intervening **variables** acting as links between **inputs** and **outputs**.

In a grey box, at least something is known about the inner **transformation mechanisms** of the box.

According to M. BUNGE, **automata** are grey boxes, which may be **deterministic** if the same types of **inputs** produce the same **outputs**, or **probabilistic** if they produce only probable **outputs**. (1979, p.263).

Such **models** "are of greater interest than **black box models** because, unlike the latter, they take into account not only the **behavior** but also the internal **states** of a system" (Ibid). **Complex systems** are similar to grey boxes, in that we know something of their internal **mechanisms**, but not enough to make them perfectly, or even reasonably **predictable**.

1469

GROOVING¹⁾

The progressive **reinforcement** by successful repetitions in a **learning process**.

In the nervous system, grooving is a result of **HEBB's rule** of synaptic circuit **reinforcement**. A similar **process** exists in all natural or artificial **learning networks**, including **social systems**. While it is needed to stabilize **knowledge**, it may lead, when excessive, to overlimiting **constraints**, that can block further **learning**.

1470

GROUP^{1) - 4)}

"A set of single **organisms**, commonly called **members**, which, over a **period of time** or multiple interrupted **periods**, relate to one another face-to-face, processing **matter-energy** and **information**" (J.G. MILLER, 1978, p.515).

This is the fourth **level of complexity** in J.G. MILLER's **taxonomy of living systems**.

A group is made of interacting biological **organisms**.

The group becomes organized in order to execute useful tasks that its participants would not be able to tackle individually.

1471

GROUP (in mathematical sense)²⁾

A **set** of **elements** provided with an internal composition **rule** with the three basic following conditions

- the **rule** is associative;
- it admits one neutral **element** e ;
- any **element** of the **set** can be symmetrized: $a \cdot a^{-1}$

(adapted from L. CHAMBADAL, 1969, p.107).

The group operates **transformations** on the **set** of the general form: $a \cdot a^{-1} = e$. This implies that the **set** is closed and self-generating, i.e. that any **operation** on an **element** of the **set** gives another **element** of the **set**.

R.D. CARMICHAEL, gives some examples of groups:

"- the **set** of integers, positive and negative and zero, the **rule** of combination being ordinary addition, (the identity (i.e. **neutral element**) is zero; the inverse of an **element** is its negative);...

"- the **set** of all real numbers except zero, the **rule** of combination being ordinary multiplication (Here unity is the identical **element**, and the inverse of an **element** is its reciprocal)" (1956, p.17).

Another interesting example are the **rotation** groups of Euclidian geometry, as for example the group - i.e. the various types of rotations around a vertical axis - that conserves the **symmetries** of an equilateral triangle.

These **transitions** can be represented by a **matrix**.

More generally, the postulates of Euclidian geometry generate a group, as they correspond to a collection of rigid motions which may transform a geometric figure into itself.

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

CARMICHAEL also states: "The **elements** common to two finite groups G1 and G2 form a finite group H known as the common subgroup of G1 and G2." (p.46).

This is useful for the formalization of partial **isomorphisms**.

The group **concept** is akin to those of **hyper-cycle** and **organizational closure**, as observed by J. SINGH (1972).

Autopoiesis could thus possibly be modeled through group theory.

W.R. ASHBY enounced the following theorem: "The lines of **behavior** of a **state-determined system** define a group" (1960, p.244). Thus the **concept** of group is related to **topological stability**.

While mathematical groups are used to study the properties of **symmetric** systems, they can also be used to classify the ways **symmetries** can break.

"The late appearance of groups in science shows that a theory based on them could only have resulted from the modern mathematical **method** of **generalization** and **abstraction**, the **method** of thinking in terms of "system".

"With such concepts as **"set"**, **"group"**, **"ring"**, **"field"**, mathematics reached a stage of great generality. The object of its study is no longer the special character of certain **magnitudes**, but the **structure** of whole **domains**. In this way it becomes possible to make statements that are valid for many different **fields**. For an over-all summary or synthesis of widely varied parts of mathematics, the notion of a group has become indispensable" (Adapted from H. BEHNKE & al., 1987)

1472

GROUP TECHNIQUE (Nominal)^{2) - 4)}

A technique "used to enable a participant group to generate, clarify, and to initially assess relative saliency of factors relevant to an **issue**" (J. WARFIELD, 1989, p.2)

WARFIELD uses this evaluation technique as a feature of his "Interactive Management" and "Generic Design Science". It is meant to reveal ideas, opinions and beliefs of participants about some **issue**, and to measure their **diversity**.

He explains the technique as follows: "Members of the group work from a **context** statement about the **issue** to generate ideas about the **issue**, silently. Then there is a round-robin recording of the ideas. Next there is a formal period of clarification of the ideas, aimed at assuring that anyone in the group has the opportunity to understand every idea. As used by the Center for **Interactive Management**, the last step in applying NGT is to ask each individual member of the group to vote anonymously on what that individual believes are the five "most important" ideas in the **set** of ideas that remains after clarification. This voting record becomes part of the permanent **data set** on how members of the group share or do not share

beliefs about relative importance of constituent factors in the complex **issue** under consideration. It allows a ranking **pattern** to be produced reflecting a group product at a certain point in time in considering the **issue**" (1991, p.198).

1473

GROUPTHINK^{3) - 4)}

"The deterioration of mental efficiency, quality of reality testing, and quality of moral judgment that results from in-group pressures" (J.N. WARFIELD and C. TEIGEN, 1993, p.4).

The authors comment: Subject to Groupthink, a group may seem to accept a specific **decision**; however, if individual group members are confronted with that point of view separately from the group, few members would accept that view as their own" (Ibid).

Groupthink results from role **dissymmetries** among group members. "Specific **behavioral patterns** found in Groupthink involve such **roles** as "gatekeeper", "whip", etc., that distinguish one member from another. Certain individuals dominate the discussion. Individuals known to have views not compatible with whatever viewpoint is being favored may be silenced or excluded from the group" (J. WARFIELD, 1995a, p.65).

I.L. JANIS, as quoted by WARFIELD describes the eight symptoms of Groupthink:

"1. An illusion of invulnerability, shared by most or all of the members.

"2. Collective efforts to rationalize in order to discount warnings.

"3. An unquestioned belief in the group's inherent morality.

"4. Stereotyped views of rivals and enemies.

"5. Direct pressure on any member who expresses strong arguments against any of the group stereotypes, illusions, or commitments.

"6. Self-censorship of **deviations**.

"7. A shared illusion of unanimity ... augmented by the false assumption that silence means consent.

"8. The **emergence** of self-appointed mindguards" (1994b, p.259).

A still more nocive variant of Groupthink is **Clanthink**, wherein *everybody* is subservient to generally unperceived mental **constraints** resulting from unexpressed - and sometimes hidden - cultural **values** and **norms**.

1474

GROWTH¹⁾

Functional and **structural** increase in an individual system or a **population**.

K. BERRIEN stated: "Growth may be viewed as **structural** modifications initiated by some "foreign" **input** permitting the acceptance of (more) **maintenance inputs**".

Accordingly:

"a. **Emergent** characteristics of systems are the necessary consequences of growth and attendant modifications.

"b. Because growth modifications are such as to permit the system to be maintained more efficiently, they can be viewed as **adaptations**.

"c. Growth is limited by **adaptation limits** and **memories**.

"d. Growth follows a "plan" **embedded** in **substructures** of the initial system modified by localized **specialization**" (1968, p.87).

According to K. BOULDING: "Some growth **phenomena** can be dealt within terms of relatively simple **population models**, the solution of which yields growth curves of single **variables**. At the more complex **levels** structural problems become dominant and the complex **interrelationships** between growth and **form** are the focus of interest. All growth **phenomena** are sufficiently alike however to suggest that a general theory of growth is by no means an impossibility". (1956, p.13).

Forty years later, we still lack such a systemic theory!

1475

GROWTH ALGORITHM (LINDENMAYER's)²⁾

An algorithm for construction of a **tree** that can generate one-dimensional **sequences**, but also apply its **rules** in several places simultaneously (After C. EMMECHE, 1994, p.74)

The algorithm is **recursive**, i.e. it functions as a programmed **rewriting process**.

EMMECHE comments that it "...can be viewed as a series of recipes or algorithms for the creation of the parts of a plant" (Ibid).

The "**trees**" thus constructed are more or less **self-similar**, which explains why many plants tend to develop a **fractal** disposition of their parts. The **models** thus generated can be made more realistic by introducing some **randomness** in the algorithm.

1476

GROWTH (Allometric)^{2) - 4)}

"The relation of the growth of a **part** or **organ** to that of the whole **organism**" (C.R. REEVE & J. HUXLEY, in HUXLEY, 1972, p.267).

This relation corresponds to the formula $y = bx^a$ or $\log y = \log b + a \cdot \log x$, given by C.R. REEVE and J. HUXLEY (Ibid). R. NAROLL and L.von BERTALANFFY showed later on that the allometric growth relation can also be applied in sociology and gave some examples, as follows:

- number of services establishments, factories and retailers in relation to urban population.
- differentiation between specialized trades in relation to population.
- urbanization in relation to total population (1956, p.76-89).

It should be noted that different **trends** may appear during the allometric growth **process**. They are probably related to differential acceleration and saturation factors which intervene at different times, particularly in **logistic** growth.

1477

GROWTH and STABILIZATION ¹⁾

St. BEER writes some curious and stimulating reflexions about growth: "...any organic seminal **programme** that inaugurates and controls growth 'knows when to stop'. This capability applies not only to the macrostructure, so that you and I are roughly the right size to be recognizably human: it also applies to the infrastructure of the **organism**: every limb, every **organ**, every parcel of tissue however delineated, from cranium to toe-nail, grows to a **limit**. During growth, further growth is by definition due to follow: **development** (except by massive intervention from outside) cannot be arrested until the plan is complete. To this extent, a partly grown **organism** is in an improbable **state**, and is driving towards its most probable **state** – adult completion. Growth can be regarded, that is to say, as an *entropic process*. The growth **process** stops when the genetic **information** is used up, actually having been finally and in sum exchanged for potentiality... Growth, then, is a **self organized activity** of a system in which that system 'learns to be what it is'" (1968, p.360-1).

In other words:

1. Growth is within each individual system the actualization **process** of an **archetypical algorithm**.
2. Growth leads inevitably to **organizational closure** and **autopoiesis**.
3. It leads as well to mature **homeostasis**, i.e. **dynamic stability**.
4. The original **archetypical** "seed" must contain an implicit potential (whatever this may mean) for **constraints** construction, probably operated through **interactions** and **connections** between its original **elements**.
5. It must contain coordinated **loops** of **self-reference** which guide the system along a typical **chreod**.

1478

GROWTH and STRUCTURATION ¹⁾

In his paper on the possibility of a general theory of growth, K. BOULDING underlines the necessary and unavoidable relation between growth and structuration.

He shows how the necessity to maintain a sufficient **input** of **resources**, as well as their **distribution** in a growing system implies also a growing **differentiation** of its **structures** and, for each functional **structure**, the need to subdivide (1956, p.71).

He uses as an example school buildings: "A one-room schoolhouse, like the bacterium, can afford to be roughly globular and can still maintain effective contact with its **environment**" (Ibid). It can receive, for example, light from its four sides. Should the school include various classrooms, it will have to be lengthened, in order to provide some light to every room. If it is still larger, internal **structures** for **communication** (lobbies, a telephone system, etc...) become necessary. It will possibly take the classical form of a comb, or create alternative internal subsystems providing light, power, heating, cooling, etc... The only alternative solution should be several separate buildings in a campus.

The alveolar or **fractal** aspect of many biological **structures** illustrates the same **phenomenon**.

1479

GROWTH (Autocatalytic) ²⁾

"A **positive feedback process** that augments the static **variety**, with the only **constraint** that the added systems belong to the same general type that "fits" the **template**" (F. HEYLIGHEN, pers. comm., p.15).

This concept seems to be specifically useful for **populations**. HEYLIGHEN gives as an example the **process** of crystallization, where the concept of **template** applies easily.

In the case of **living systems** the concept of basic type or **archetype** corresponds to the one of **template**: the number of members of a species increases, but they remain true to type, i.e. no new species does appear.

1480

GROWTH CENTER ²⁾

The apex or extremities of the system or some other limited sectors become its centers or poles of growth.

It seems that the possibility of more or less free **interactions** between an extremal **zone** of the system and its **environment** is a stimulating condition.

However, the **compatibility** of the new **structures** and **functions** abuilding with those already in existence is by no means guaranteed. This may then produce:

- a fission or split, which may lead to the **segregation** of a **part** of the system and, possibly to the genesis of a new system.
- an internal reorganization which may lead to an important modification of **objectives**, internal **structures** and **functions** or even of the very **identity** of the system.
- the suppression by the systems **controls** of the new **parts** or **elements**, seen as undesirable or dangerous.

1481

GROWTH CURVES ²⁾

Growth is a very general feature of **processes** and systems. It has however also quite diversified characteristics in different cases.

The following listing is a selection of the most useful growth curves related to specific types of processes:

1. Asymptotic: permanently slowing down growth
2. Chreodic: periodic (fluctuating) growth within a growth **trend**
3. Exponential: permanently accelerating growth (i.e. explosive)
4. Lineal: constant arithmetic proportional growth
5. Logarithmic: **exponential** growth defined by a characteristic exponent
6. Logistic: an accelerating growth phase preceding a decelerating growth phase, due to a **negative feedback**
7. Normal (Gaussian): statistical distribution (Bell shaped curve) that can also represent a growth and **decay** sequence
8. Periodic: fluctuating growth or dynamic **oscillations** around a median. Frequently superposed on another curve
9. Semi-logarithmic: growth expressed in percentages (**ratio scale**)

Without being a growth **phenomenon**, celestial bodies orbits are also described by geometric curves in the **time** dimension. they can be hyperbolic, parabolic or elliptic. In this case, they are periodical, but their **periodicity** may be variable and unstable

→ **Chaos; Criticality (self-organized; chaos, curve (Involving); Cycles; Fourier analysis; Power laws; Self similarity in the Weierstrass function; Vortex**

1482

GROWTH (Differential) ²⁾

The various **parts** of a system may grow at different **rates**. As a result a very considerable **variety** of **forms** may appear.

D'Arcy W. THOMPSON (1916) showed that at any time the **form** of an **object**, an **organism** or an **organization** is the necessary result of the laws of its growth, until that moment. K. BOULDING expressed this as follows: "Anything which is growing uniformly will become a sphere. That which grows more rapidly in one direction will become long and that which grows more quickly on one side than on the other will twist into some sort of spiral" (1956, p.72).

1483

GROWTH (Directional) ²⁾

That growth be generally unequal in different directions is a basic condition for differentiation.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

One cause of directional growth is expressed by C. ZELLER: "Growth becomes directional if, on one side of a minimal **aggregation** unit, free **elements** are more readily available than on the other sides" (1967, p.54).

ZELLER also states: "With the initiation of **asymmetric** growth, ... a plan of **development** of the **aggregate** is laid down" (p.55).

This is the **environmental** cause of directional growth. It is difficult to pinpoint internal conditions of the growing system that may lead to the same **trend**, but their existence is doubtless, at least in biological and **social systems**. Internal **asymmetric** growth is probably related to the different **levels** of **energy flows** and of spatial **substrate** available for **subsystems** at different times.

M. MARUYAMA's **models** of **deviation-amplifying processes** illustrate the subtle **interactions** of **rules**, as applied on **initial conditions**, which lead to directional growth.

1484

GROWTH (Divergent)²⁾

A mode of growth related to the **FIBONACCI series**, for example in vegetals.

Divergent growth is a radial movement from a center towards periphery. It reflects a logic of **space** occupancy through the **time dimension**.

The result is a progressive structural construction through **iteration**: The **time dimension** is reflected in **helical forms**. The growth ratio responds to the so-called **generative helix**, characterized by a **divergence** angle, which remains constant during growth.

In most cases, the subjacent **rules** of growth seem to respond to **FIBONACCI series** and produce spiraled **forms**, which probably result from intertwined **energy fields**, rooted at the physico-chemical **level**, in accordance with TURING's concept about "The chemical basis of **morphogenesis**" (1952).

The rate of growth, which is **nonlinear**, is under two **constraints**: one corresponds to **energy inputs** and the other to the limitation of available **space**. As a result, **space** occupancy takes place on a **space-time** curve akin to a geodesic. (In vegetals, converging towards the apex).

In plants, the limited **space** available for growth is defined by a fraction consisting of **two FIBONACCI series**: one as numerator, the other as denominator.

Divergent growth, as a mode of **space** occupancy, could probably be usefully researched in many other disciplines.

1485

GROWTH (Explosive or Exponential)^{1) - 2)}

The characteristic of a growth **phenomenon**, **process** or **rate** constantly submitted to a **positive feedback**.

Any system affected by this type of growth is quickly running toward its destruction, because it is using up evermore growing quantities of some specific **resource** obtained from its **environment**, until the moment the **resource** becomes scarce and insufficient to maintain the rapidly growing **structures** of the system.

According to K. BOULDING's (himself an economist) barbed comment: "Anyone who believes that exponential growth can continue indefinitely in a finite world is either a madman or an economist" (1973, p.92).

As stated by J. MILSUM: "The basic growth **process** is of necessity escalatory or **unstable**, at least over a reasonable working **range**" (1968, p.27).

Such **situations** are very dangerous as they are generally not clearly perceived until the terminal **runaway process** is well on its way and cannot anymore be stopped. A dramatic **collapse** becomes then unavoidable.

This type of **runaway** growth is frequently observed in some physical **phenomena**, in ecology, in man-made disasters, in financial panics and in economics, as for example hyper-inflations.

Their early detection and avoidance could be one of the most important contribution of cybernetics and systems to practical activities in general.

1486

GROWTH (Limits to)^{1) - 4)}

1. This is the title of the famous first report to the **Club of Rome** (1972), which concluded that the limitless demographic and economic growth of mankind was an impossibility and would necessarily lead to a crash within a (historically) very short **time**. (D.H. MEADOWS et al., 1972).

This work led to massive controversy, for a number of quite different technical, conceptual and political reasons. The technical ones were related to the construction of the **model**, based on the specific ways of use of FORRESTER's **systems dynamics**. More than 20 years later, this debate is still not settled (See D. MEADOWS et al: "Groping in the Dark", 1982, and subsequent comments).

The conceptual reasons are principally about the real possibilities to define which **data** are relevant, to obtain sufficiently reliable ones on a sufficient **time span**, and even the possibility to construct any such complex **model** with a real predictive power.

The political reasons are related to the premises selected by the authors of this **model** (and the subsequent ones) referring to the needs and hopes of different human groups in the world.

In any case, the basic concept is about the impossibility to pursue an illimited (and nowadays exponential) demographic and economic growth. MALTHUS may have been mistaken for two centuries, but he probably won't be forever.

See "Growth (explosive)"; "Growth (Logistic)"; "Growth and stabilization"; "Growth (Rate of)".

2. A deeper interpretation of limits to growth has been proposed by K. BERRIEN: "... systems... are limited in their **variability**; hence, **adaptations** also are limited. It is not possible for a system to adapt to everything. It is this limitation in **adaptability** that prevents a system from growing to infinite **size**. Thus, institutions as they grow, face, among other problems, one of internal **communication**... The system ceases to grow, partly because it is unable to adapt to the internal **integration** problems of further growth" (1968, p.80).

This may be the deepest available explanation for **hierarchy** in **sociality**: beyond some limits at a defined **level** of **complexity**, growth becomes impossible. It can however be resumed if a number of systems at that **level** integrate themselves into a system of higher **level** of **complexity**.

1487

GROWTH (Logistic)^{1) - 2) - 4)}

Logistic growth **processes** are characterized by the progressive limitation of growth due to a **saturation** factor, *which is directly proportional to growth itself*.

The acceleration of growth *precedes* the acceleration of the **saturation process**. Growth tends thus to look firstly **exponential or logarithmic**, but will generally slow more and more down as the growth **process** goes on. The alternative is destructive **runaway** or **explosion**.

In J.H. MILSUM's words: "... the decay of the growth **rate** essentially follows a mirror image **pattern** to the initial increase of growth **rate** until a **steady-state population** is reached, typically under a constant nutrition condition" (1968, p.43).

The implicit character of the **saturation process** at its beginning, makes it difficult to perceive before it is already in full swing. This is a dangerous **situation**, specially in relation to many growth **processes** triggered by man, for which the **saturation** factor is not yet perceived.

Serious problems could surface later on (climatic, demographic, ecological and the like). Besides, the most swift **processes** of growth are also the most exposed to violent braking **processes**.

1488

GROWTH (Nonlinear)²⁾

Any type of growth in which the **outputs** are not in an arithmetic relation with the **inputs**.

The relation can be logarithmic, exponential, logistic, asymptotic, etc...

For sound **predictability**, it is important to take the specific type of nonlinearity in account in any **extrapolation**; or to reckon one's uncertainty about the type of nonlinearity.

1489

GROWTH OVERSHOOTING^{1) - 2)}

The **process** by which a system overpasses grossly its optimal dimensions.

A system can remain **dynamically stable** only if two basic conditions are fulfilled:

- the **level** of its **energy** supply is permanently adequate, and
- the **waste** it produces must be disposed of and assimilated by the **environment** at a sufficient **rate**.

These conditions are not always present. When the **energy** supply is over-abundant, the system (specially **populations**) may grow in excess up to a non-permanently sustainable **level**. Worse still, this generally increases **waste** production and can make it unassimilable by the **environment**, in which case the system may asphyxiate in its **waste**.

The main problem here is that many systems also suffer of the effects of a **time-lag**: the nefarious **side effects** are not perceived until they become overpowering and in some cases an irreversible destructive **situation** develops.

This is probably a danger that presently threatens mankind under various disguises.

1490

GROWTH (Principle of autocatalytic)^{1) - 2)}

"Stable **configurations** that facilitate the appearance of **configurations** similar to themselves will become more numerous" (F. HEYLIGHEN, 1992, p.4).

HEYLIGHEN readily admits that this principle is self-evident. However, he adds that it "... describes as well biological **reproduction** as the **positive feedback** of **nonlinearity** characterizing most inorganic **processes** of **self-organization**, such as crystal growth. The principle simply states that it suffices for a **configuration** to be **stable**, and in some respect autocatalytic or **self-replicating** in order to undergo a potentially explosive growth" (Ibid).

In any case, autocatalytic growth is possible only if the following conditions are fulfilled:

- The substrate or **environment** must be able to supply the needed material and/or energetic **resources** for growth;
- A **template** for **self-replication** must be present.

Besides, growth remains unchecked only as long as the **environment** does not become overexploited or supersaturated.

1491

GROWTH (Semi-logarithmic)²⁾

A form of growth that remains constant over time in percentage terms.

The semi-logarithmic scale **representation** is very significant because it shows that an arithmetical growth, even when accelerating, can be merely a constant one in relation to the basic evolution of the **process** considered.

The **ratio scale** should be used to represent semi-logarithmic growth.

1492

GROWTH: Quantitative or qualitative^{2) - 4)}

According to D. KATZ and R.L. KAHN: "The basic type of system does not change directly as a consequence of expansion. The most common type of growth is a **multiplication** of the same type of **cycles** or **subsystems** - a **change** in quantity rather than in quality" (1969, p.98).

This mode of growth has been confirmed for numerous **populations** and **social systems**, in which the proportions of the different **groups** remain constant.

"Qualitative **change** does occur, however, in two ways. In the first place, quantitative growth calls for supportive **subsystems** of a specialized character, not necessary when the system was smaller. In the second place, there is a point where quantitative **changes** produce a qualitative difference in the functioning of a system" (Ibid). Indeed, problems caused by a growing **density**, by longer **communication** lines or **channels**, modified **morphological** relations, etc... do appear and impose the **emergence** of **subsystems** of **support**, **coordination** and **control**.

The present **multiplication** of new types of **subsystems** for specialized services in **human systems**, due to their enormous quantitative growth is a quite typical example.

1493

GROWTH RATE^{1) - 2)}

The relative speed of growth by time unit.

According to K. BOULDING, every system has an optimum or equilibrated rate of growth. He adds: "... (a) higher or lower growth rate may seriously disturb the functioning of the system, even to the point of its **collapse** and "death". (1956, p.74).

BOULDING gives some examples from botanics and economy. Such abnormalities are obviously very frequent and could be generally named "*disturbances of growth rates or rhythms*". They seem to be linked to **disruptions** of the **equilibrium** between the relative

growth of various **functions** and **structures** (or **subsystems**), induced in some cases by internal causes and in other by **environmental** factors.

This **phenomenon** has been reported in quite different fields as, for example, in human biology, physical and mental **lags** because of a deficient alimentation during childhood; or in **management**, a crisis of general disorganization provoked by an excessive rate of growth.

Referring themselves to GOETHE (the so-called "Budget Law") and Geoffroy de SAINT-HILAIRE ("Loi de balancement"), R.S. NAROLL and L.von BERTALANFFY write: "...in an **organism**, there is a characteristic and constant "**equilibrium**" between the **organs** and, as we may add, the chemical **components** as well. So **overdevelopment** of one **part** will be corrected by lack in an other **part**" (1956, p.79).

The subject is thus at the same time closely related to **allometric growth**.

K. BOULDING again writes: "Growth at any rate... cannot take place without the **organism** eventually becoming "large" and diseconomies of **scale** may set in. The ideal rate of growth, therefore, may properly be regarded as a diminishing **function** of the **size** of the **organization** and will eventually diminish to zero" (1956, p.39-40).

This affects **organisms** as well as **organizations**, and probably explains the very general transition of systems of many types from growth to **dynamic stability**. It could also be the basic reason why individuals of any type, limited in **size**, tend to socialize and form more **complex systems** on a higher **level of organization**.

1494

GROWTH-RATE PARAMETER²⁾

The factor which controls **growth rate**.

Since no growth **process** is independent of its **environmental** conditions and/or intrinsic characteristics, none can be **linear** at **long-term**. This must be reflected into growth equations if real **situations** are to be satisfactorily modelled.

Thus a growth-rate parameter must be introduced into the equation.

According to J. GLEICK: "In the physical systems from which these equations were borrowed, that parameter corresponded to the amount of heating, or the amount of friction, or the amount of some other "messy" quantity. In short, the amount of **nonlinearity**" (1987, p.63).

R. JENSEN uses as an example a very simple difference equation:

$$x_{n+1} = ax_n(1-x_n) \text{ or } x_{n+1} = ax_n - ax_n^2$$

He writes: "The **time-evolution** of x_n generated by this single algebraic equation exhibits an extraordinary **transformation** from **order** to **cha-**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

os as the parameter a , which measures the strength of **nonlinearity** is increased" (1987, p.170).

For x included between 0 and 1 and for different values of a , JENSEN distinguishes the following cases:

- for $a = 1$ - Growth followed by monotonic damping and extinction;
- for $a = 2,9$ Growth toward an **asymptotic stability** with a punctual **attractor** (variable according to the value of a);
- for $a = 3,2$ Growth followed by **fluctuations** around a **stable cycle limit**;
- for $a = 4,0$ Growth followed by apparently **random fluctuations (chaos)**.

For a clearer understanding, see reference.

1495

GROWTH REGULATION¹⁾

Numerous authors have observed that growth is in general in no way an anarchical **phenomenon** in systems.

The most frequent model is **logistic growth**.

C. WADDINGTON, for example, showed that growth goes with **fluctuations** around a basic **trend**, within a kind of guiding **channel** which he called a "**chreod**".

However the precise mechanism and fundamental cause of growth regulation are still ill understood.

All systems seem to count with internal **norms** relative to their global and maximal **dimensions** as well as those of their different **subsystems**. But it is quite difficult to pinpoint the **elements** or groups of **elements** which are the bearers of these **norms** and how they command their more or less strict observance.

Moreover, while **fluctuations** are a result of the need to maintain the global and local **equilibria** of internal **structures** and **functions**, they are also correlated to **environmental variations**, significant for the system (as for example the seasonal growth of plants or the acceleration or deceleration due to climatic **variations**).

See for ex.: **Circadian rhythms**

1496

GUESS²⁾

"A question which can be answered by "yes" or "no" (A. RAPOPORT, 1966, p.6).

This is a very useful notion for the evaluation of the **quantity of information**.

A. RAPOPORT explains: "It can be easily seen that a number from one to one hundred can always be guessed in seven guesses, while a number from one to one million can always be guessed in twenty guesses. To do this one needs to make guesses in such a way as to eliminate one half of the remaining **range**. In the case of a million, one starts with: "Is it less

than 500.000 ? If yes, "Is it less than 250.000 ?". If no, then is it less than 375.000 ?", etc. Since one million is less than 2^{20} , it will take at most 20 such **dichotomies** to determine the number" (p.6).

1497

GUIDANCE (SELF-) ⁴⁾

T. GOGUEN FRANTZ proposes what she calls "evolutionary guidance systems (EGS's)", which can help persons "to **design the organization** they ideally would like to become at some time in the future..." on the base of "an **image**, clear enough, attractive enough..." and eventually "**consensually agreed upon**" (1991, p.79).

FRANTZ adds (describing the **graph** shown in her paper): "EGS's must keep the **image** vivid for everyone and must keep it updated. For that reason iterative **cycles of information** are shown flowing from a past or present institutional **state** to the EGS and from it to a future **state** of the institution. Multiple **states** are

Figure: see entry **GUIDANCE (SELF-)**

Guidance (Self): an example

From T. GOGUEN FRANTZ: 1991, p. 78

shown for the EGS, because it co-evolves with the system it serves" (Ibid).

This is an interesting idea, which may be very helpful to psychically mobilize people. However, some caveats seem to be necessary. No EGS could suddenly appear out of the blue: it is unavoidably based on **values** and **norms** (how things *should be*), which are not neutral, being in the best case, culture-borne.

An EGS could however also be shaped by some ideologues (individuals or closed knitted **groups**), whose well known insulation from anything that may contradict their beliefs makes them good candidates for inquisition, intolerance and autocracy, at times even cloaked in a pretense of open mindness.

Systemic guidance should imply a maximum possible genuine **openness**, which is the only way to insure that the quota of **invisibility** is as low as possible.

True guidance should be based on mental devices for taking a clear conscience of one own's basic **values** and **norms**, and for their **evaluation**. This implies taking distance from oneself, one of the most difficult psychological exercise, for sure.

At least, some systemic concepts may help as for example **semantic** critique (KORZYBSKI) or the notion of **mindscapes** (MARUYAMA).

H

1498

HABIT ⁴⁾

Any **pattern** of **behavior** acquired through **imprinting**, **training** or **learning**, and more or less definitively fixed.

According to C.S. PEIRCE, repeated **inferences** are leading to the establishment of a habit (U. ECO, 1979, p.17).

Habit formation in turn is the way to **algorhythmization** and subsequent **automatization** of **behaviors**. G. BATESON states that it: "...is a major economy of conscious thought" (1973, p.115), as it applies to "... the solution of *classes* of problems" (p.245). Moreover, the necessary parsimony in the use of neural **circuits** implies that: "No **organism** can afford to be conscious of matters with which it could deal at unconscious **levels**" (p.116). This is true for man. On a lesser mental **level**, it is also true for animals, as shown by J.von UEXKÜLL and G. KRISZAT (1928, 1934), K. LORENZ and other **ethologists**.

Habit formation is a progressive **process**. It is easy during infancy, less so during adolescence and quite more difficult in adult age, probably because it must be a **process** of **connections** formation in the **brain's neural network** and in adult age, frequently a **process** of replacement of existing **connections**.

As to the unconsciousness of habits, BATESON observes "... that the "unconscious" includes not only repressed material but also most of the **processes** and habits of **gestalt perception**" as we are "... unable to say clearly how this **pattern** was constructed, nor what clues were used in our creation of it" (p.272).

1499

HABIT EXTINCTION ⁴⁾

The spontaneous or willful elimination of a habit.

A habit may spontaneously disappear if it is not more or less frequently reinforced. However, it seems that basic habits acquired early in life never disappear definitively, even if the **organism** is unaware of their survival.

The willful elimination of a habit requires a considerable effort of conscious deconditioning, and retraining if it is to be replaced by another habit. Such a **process** is generally impossible at the physiological **level**.

At the psychological and mental **level**, it is still quite difficult and can be painful as stated by G. BATESON: "... Any freedom from the bondage of habit must also denote a profound redefinition of the self" (1973, p.275).

The different degree of resistance of habits to **change** seems to be related to the relative paleontological antiquity of the different **brain structures**, as they were formed.

The study of habit formation and extinction in learning **automata** will probably teach us much about habits in **living systems**.

1500

HABIT FORMATION ⁴⁾

The progressive acquisition of fixed mental **patterns** and **behaviors** through **imprinting**, **training** or **learning**.

From the physiological viewpoint, recent research seems to indicate that habit formation and retention take place in "two fundamentally different **learning** and retention systems. These systems use different circuitry within the **brain**, store different aspects of experience and follow different **rules** of **storage**" (H.L. PETRI and M. MISHKIN, 1994, p.36). The **brain** seems to be a **network of networks**. This is important for the **understanding** of our normal as well as pathological mental **processes**.

Habit formation presents various aspects:

- 1) It is based on experimental recognition of repetitive **situations** or **patterns**.
- 2) it supposes the **perception** of at least a degree of coherent **complexity** (through appreciation of recognized **Gestalten** and their **contexts**).
- 3) it implies the progressive **stabilization** of specific and coordinated neural **feedbacks** in **nets**.
- 4) it becomes efficient by **compression** of **redundant data** into standardized **perceptions**, shaping of **mental maps** and of totalizing **concepts**.
- 5) it supposes the substitution of "... a deeper and more enduring change for a more superficial and reversible one" (1973, p.321).

In G. BATESON's words: "The **phenomenon** of habit formation sorts out the ideas which survive repeated use and puts them in a more or less separate **category**" (p.477).

This is also true for behavioral habits.

1501

HABIT INTERFERENCE (Principle of) ^{2) - 4)}

"Old **memories** interfere with the acquisition of new ones" (K. BERRIEN, 1968, p.81).

BERRIEN gives examples: "A tree that is bent by the prevailing winds to the east will snap off if forced in the opposite direction. An **organization** developed to sell automobiles is not likely to grow by gradually taking on the sale of road-making machinery" (ibid).

BERRIEN was probably unaware in 1968 of the **autopoiesis** and **organizational closure concepts**, which explain why habits tend to block the acceptance of novel ways or **behavior**.

1502

HABITAT ¹⁾

"The sum of **environmental** conditions in a specific place occupied by an **organism**, **population** or **community**, where it naturally grows and lives" (UNESCO - UNEP glossary of **environmental** education terms - 1983, p.16).

This term is mostly used in **ecology**, including human **ecology**.

1503

HABITUATION ¹⁾

A very simple form of **training** through which a **living system** subjected to repeated **stimuli** tends to produce diminishing **responses** (after W.R. ASHBY, 1960, p.189).

Habitation is primarily a property of **neural** systems. It "consists in the weakening of existing (wired-in) synaptic **connections** with repeated **stimulation**" (M. BUNGE, 1979, p.163).

According to ASHBY this **behavior** "...is to be expected to some degree in all **polystable systems** when they are subjected to a repetitive **stimulus** or **disturbance**" (ibid).

This of course, is true only if the **stimulus** or **disturbance** is non-destructive, or so dangerous that it elicits other types of **reactions** (as for example fighting or escaping).

It would be interesting to verify if **artificial organisms** could be trained in this way.

1504

HABITUS ⁴⁾

The structural and permanent basic result of **training** in the trained individual.

An example is the pianist, who becomes a good interpreter only after having acquired the basic automatism of piano play.

At a second **level**, improvisation or composition become possible only after the basic **codes** and styles of music have also been incorporated.

Of course both **levels** of **training** are different for other instruments as for example violin, or clarinet. They also differ in distinct types of music, as for example in jazz or in indian ragas.

More generally speaking, any trade is necessarily grounded in some specific habitus.

Habitus is transmitted within specific **socio-cultural fields**.

1505

HALTING PROBLEM²⁾ - 3)

TURING demonstrated by his **uncomputability theorem** that there is no effective mechanical procedure for deciding whether an arbitrary **program** will ever finish its computation and halt.

G. CHAITIN thus parallels TURING'S work with **GÖDEL's incompleteness theorem**: "Kurt GÖDEL, the Austrian logician and Alan TURING, the father of the computer, showed that it is impossible to obtain both a consistent and complete axiomatic theory of mathematics and a mechanical procedure for deciding whether an arbitrary mathematical assertion is true or false, or is provable or not" (1990, p.44).

CHAITIN himself connected both aspects of this intrinsic limit to logical systems **validation** through his concept of **algorithmic incompressibility**.

According to J. CASTI: "... since the two problems are logically equivalent, the fact that the Halting Problem has no solution implies that the **Decision Problem** is also unsolvable. So we run up against a brick wall in trying to get to the heart of things by following a set of **rules**" (1990, p.137).

Of course, more or less provisionally and satisfactory solutions of any practical **decision problem** still remain possible. But we should always be aware of their **limits**.

1506

HAMILTONIAN SYSTEM²⁾

A system whose study is amenable to Hamiltonian mechanics.

Hamiltonian systems are governed by Hamiltonian **dynamics** i.e. in R. THOM's words "A **dynamics** where there is no **energy** lost through **dissipation**" and as a result "the look of **trajectories** is not notably modified" (1993, p.41).

M. FARGE writes: "Hamiltonian mechanics deals only with **stable states**, or **close to equilibrium**, and describes only conservative, i.e. reversible **phenomena**, while turbulent **flows** are highly **unstable** and **dissipative**, i.e. **irreversible**; moreover classical **dynamics** always started from systems with few interactive **elements**, without a great number of **degrees of freedom**" (1992, p.212).

Only **homeostatic systems** are amenable to Hamiltonian mechanics, because in G. NICOLIS words they: "admit a **variety** of conservation laws, **constraining** their **evolution** very strictly". But "as a counterpart they present rather poor **stability** properties in the sense that their **evolution** remains strongly dependent on the **initial conditions**" (1981, p.188). In other words, they are tightly **deterministic**. **Dissipative, bifurcative** systems are **unstable** and non-Hamiltonian. Note the correlation with POINCARÉ's **3-bodies or n-bodies problem**.

Now that **deterministic chaos** and **dissipative structuration** have been discovered and researched, it becomes obvious that Hamiltonian systems and **dynamics** are rather abstract and theoretic **models** of not so common systems or very simplified ones.

1507

HAMMING DISTANCE²⁾

"A measure of dissimilarity between **patterns**" (P. DENNING, 1989, p.333).

This measure is expressed as the number of **bits** in which the considered **patterns** differ. DENNING offers a very simple example: "... the distance between 01100 and 10110 is 3 **bits**" (Ibid).

1508

HANDICAP²⁾⁴⁾⁵⁾

The relative **cost** advantage or disadvantage of producing a **signal** or an **output** in relation to the **level** of **resources** available to its **transmitter**.

This apparently abstract definition widely applies among animals and humans. "In 1982, evolutionary biologists W. HAMILTON and M. ZUK proposed a new handicap hypothesis that forged a **link** between the quality of individuals and their sexual **signals**... In essence, only males with genes for, say, parasitic resistance would be in prime condition and thus able to express the best sexual **signals**" (M. WALKER, 2000, p.23). WALKER observes that, in more subtle ways, this is even true for human males.

Based on this observation, A. ZAHAVI proposed what he calls the "handicap principle", which is in essence a quite general evolutive **selection mechanism** (Ibid).

In human societies at different **levels**, the validity of the handicap principle is also probable. Powerful **organizations**, with an abundance of available **resources**, are able to resist strong **perturbations**, and to promote themselves in a more efficient manner.

1509

HARDWARE⁵⁾

"The mechanical aspects of a computer, excluding the **set** of instructions given to the coomputer by the programmer (called Software)" (T.F.H. ALLEN & T.B. STARR, 1982, p. 269).

1510

HARMONIC ANALYSIS→ **Fourier analysis**

1511

HEBB'S RULE²⁾

"...a synaptic **connection** that is used often will increase its strength so that the probability that it will be used later on increases".

This rule, quoted by F. HEYLIGHEN (1990b), may seemingly be extended to any type of **learning network**, able to learn by experience. It is however ambiguous, since it may lead the **network** into a rut, as in Pavlovian and Skinnerian conditioning.

St. KAUFFMAN describes this situation: "... a difficulty with most versions of the Hebbian synapse is that the system tends to dig itself into a Hebbian hole deep in the solid **regime**. **Attractors** tend to become too deeply grooved into the system. This **embedding** may inhibit flexible **learning** by trapping the system too readily in suboptimal **responses**" (1993, p.229).

This could be called the *grooving* problem and its possible relation to **organizational closure** should be investigated. This could even be significant in **social systems**.

1512

HELIX^{1) - 2)}

The **trajectory** in **time** of a cyclical **process**.

The helix can be cylindrical, or conical.

A cylindrical **trajectory** corresponds to **dynamic stability** of the **function** or system thus modeled. The conical helix (i.e. the spiral) when opening, corresponds to an expansive **process**, that may eventually end up in a **run-away event**. The closing helix indicates a trend toward **asymptotic stability**.

Ch. LAVILLE showed that helices are brachystochronic **trajectories** in a **vortex**, i.e.: "... the **trajectory** corresponding to the highest velocity or the least energetic expense... joining the starting point and the terminal one" (1950, p.51).

This explains the relative predominance of helicoidal movements and **forms** in nature, in relation with the least possible production **level** of **entropy** in **dynamically stable systems**.

H.C. SABELLI states that the helix is a **representation** of dialectic movement: "... because **evolution** has two components: 1) a **reversible change** in which thesis and antithesis symmetrically negate each other and the synthesis represents a return to the thesis, following its definition as a negation of the negation; and 2) a non-reversible **process** for which all three stages represent a movement in the same direction" (1994, p.353).

→ **Vortex**

1513

HELLENIC SYSTEMS SOCIETY¹⁾

The Greek Systems Society was founded by M.DE CLERIS and a number of Greek systemists.

It has published a **Systems Handbook** in Greek.

It also organizes tutorials and international meetings, notably in Creta. It is member of the IFSR and of the European Systems Science Union.

1514

HERD EFFECTS ¹⁾²⁾⁴⁾

The protective effects for individuals resulting from congregation in considerable numbers.

Such effects can be observed in numerous different animal species: fish **shoals**, nesting birds, gregarious mammals, insects flights, etc...

Those individuals at the center of the herd are better protected because they are completely surrounded by individuals of the same species which are not dangerous to them. The peripheral individuals are more at **risk** because, on the outer ring, they are in direct contact with the **space** of possible predators. In most cases "insiders" and "outsiders" rotate, which is globally efficient for the whole flock.

Observing nesting birds, Diane BRUNTON (Yale University) discovered that the central area is at a disadvantage when the predator is airborne, thus able to make use of the third **dimension**. In that case, the central **density** of the flock offers increased opportunities to the predator.

(Source: The Economist, Oct. 18th 1997)

→ **Edge effect**

1515

HERD IMMUNITY ²⁾⁴⁾

The resistance to **propagation** of a contagious **process** in a **composite system** when the contagious **element** is insufficiently numerous.

C. WILLS writes: "If most of a herd is immunised against a disease, that disease can no longer spread easily, and the few unimmunised animals are also protected" (1996, p.41).

In more general terms, **avalanches** and other **percolation effects** in **composite systems** occur only if a **critical density threshold** of the perturbing **elements** is crossed.

Herd immunity is related to the degree of **diversity of elements** or **evenness** in the defined space.

1516

HERMENEUTICS ³⁾

The science of interpretation of texts and **symbols**. Originally hermeneutics was concerned with biblical scriptures and philosophical commentaries. It has however been widely extended during the last century, for ex. by DILTHEY (1922, 1935)

Hermeneutics is closely related to **semiotics**, the science of **signs** and their **meanings**

By extension, the science of the interpretation of human individual and social **behavior**.

What people think they themselves are doing, as well as what other people are doing is of course not necessarily the same as what they are "really" doing. The problem is obviously the **meaning** that should be given to the word "really", as it does not seem possible to establish perfectly objective **criteria** for describing "reality". This is specially true in human sciences, in which **values, norms, mental frames**, etc... can never be "**objective**".

J.Z. YOUNG shows himself somewhat skeptical about hermeneutics as a science when he defines it more modestly as "the study of the supposed fundamental significance of human thoughts, utterances, **actions** and institutions" and observes that "Hermeneutics was used originally by theologians for interpretations of the truths in the Bible" (1978, p.293).

Of course, the study of human conditions of **knowledge**...by humans is by its nature always relative and possibly questionable. It is however better than the mere naive uncritical **belief** of an **observer** who does not understand his own defined and limited mental and psychical conditions or, as said by Ortega y Gasset, his belief in his own **transparency** as observer (1965, p. 145)

The German philosopher Hans GADAMER (1900-2002) is generally considered to have founded Hermeneutics (J. GRONDIN, 1995, 1996, 1999). Much of his work has its roots in the pre-socratic greek philosophers, among them Heraclitos and Parmenides.

→ **Autogenesis, Ontological skepticism**

1517

HETERARCHICAL – HOLOGRAPHIC ORGANIZATION ⁴⁾

J. A. JOHANNESSEN who developed this **model** states the following **criteria** as requirements for a heterarchical or holographic organization:

1. The **whole** enclosed in its **parts**
2. **Double-loop learning (deutero learning)**, with **communicative competence**
3. Fewer **levels of management**
4. Liquidation of a centrally managed **command and control model**
5. Transition to a "flatter" organizational **structure**
6. Clearly defined **goals** leading to **action**, where the results, plans and **goals** can be evaluated explicitly
7. More emphasis on individual responsibility for contact and **communication**
8. More emphasis on the overall view
9. Organizational **design** favoring innovations and **autonomy**
10. The gathering of **information** a more distributed **process**
11. The transition from **data** processing to complete informative systems
12. Flexibility and freedom for the individual members of the **organization**
13. Involvement by all in the **planning process**

14. Creating the future, not predicting it

15. Cybernetic principles as the foundation for organizational **design**

16. Self-organizing, **autonomous small groups**

17. Global **information** can be taken out locally and local **information** can be taken out globally.

In holographic terms: each part of the organization contains enough **information** to recreate the **whole**" (1991, p.41-42).

1518

HETERARCHY ^{1) – 2) – 4)}

A decentralized arrangement of **nodes** in a **network**.

This concept was introduced by W. Mc CULLOCH who explained that the **relationships** among the **nodes** may be variable, and even contradictory.

Heterarchy can also be defined as a non-centrally distributed system of **components** with various interconnected focal **elements** in a hierarchical **organization**.

Heterarchy is quite different from the tree-like classical **hierarchy**. Not every **decision** must be here taken or controlled by the top power. Moreover, many **elements**, if not all, are multivalent and may, up to a point, play different **roles** in the system and replace each other.

According to G. WEINBERG, many attempts to use strictly **hierarchical models** are ill adapted to **complex systems** (and particularly, **human systems**), which are more like hybrids of **hierarchical** and heterarchical systems (1972, p.272).

1519

HETEROCHRONY ¹⁾²⁾

A differential **rate of growth** and/or **development** in a living **organism**.

Heterochrony can be understood in two different **meanings**:

- 1) The differential **growth rate** of different **organs** in a living being. For example, in the human species, the head grows more than the rest of the body at the embryonic and fetal stages, but this trend is reversed after the birth.
- 2) The different rate of embryonic development in different species. The German biologist Ernst HAECKEL (1834-1919), comparing embryos of different species during their development, came to the conclusion that, at least in vertebrates, different growth rates produced very different animals from quite similar embryos. His idea that "**ontogeny** recapitulates **phylogeny**" proved later on to be a too simple evolutive principle. (Ken McNAMARA, 1999, p.1-4)

In fact, **neoteny**, i.e. the conservation in adults of embryonic or juvenile biological **structures**, appears to be a truer evolutive **process**. It is also of course related with heterochrony.

1520

HETEROGENEITY^{1) - 2)}

Coexistence in a **complex system** of a number of **subsystems** of different types.

Any **complex system** must carry out a **variety of functions** in order to maintain its **activity**. If **complexity** results of the complementary **association** of numerous **components**, these **components** need necessarily be of different kinds. This may be observed easily in human as well as in biological systems.

Heterogeneity is a sine qua non condition of **complexity** because it allows the **emergence** of **synergies** and increases enormously the system's **variety**, which thus becomes **polyvalent**, its capacity of useful **interaction** with its **environment** being as a result, vastly enhanced.

Heterogeneity expresses itself at various **levels** in most (if not all) **complex systems**: the specialized **components** are generally themselves **complex systems**. J.G. MILLER did demonstrated this in a very thorough manner in his "**Living Systems**" (1978).

A. ANGIAL used the expression "unitas multiplex" which makes perfectly clear the idea of a complex multiplicity within a **whole**, but it never became of common use (1969, p.27).

Heterogeneity grows by **differentiation** processes, as for example:

- MARUYAMA's **deviation-amplifying mutual causal process**;
- BENARD's **dissipative structuration**;
- von FOERSTER and ATLAN's **order from noise**;
- PRIGOGINE's **bifurcations** originated by giant **fluctuations** in **systems far away from equilibrium**.

Its development needs a source of **energy** and an internal **variety** sufficiently wide to be moderately constrained. Unrestricted heterogeneity would lead back to **homogeneity** and to the systems demise. Excess of **constraints** would finally block it, which is another road to destruction.

Heterogeneity also presents a temporal **dimension**: The different **parts** or **subsystems** transform themselves along different **rhythms** and **cycles** in **time**, while these **rhythms** and **cycles** combine to produce a global and generally very intricate **behavior**.

Finally, space heterogeneity as an **environmental** condition favoured the appearance of heterogeneous systems. According to the German biophysicist H. KUHN : "The driving force for the **self-organization** of **matter** is seen in a specific **environmental structure** to be found on the surface of the earth. By this **structure**, which is **periodic** in **time** and heterogeneous in **space**, **evolution** is initiated and driven towards a continuously increasing degree of **complexity** correlated to a continuous expansion of the accessible living **space**" (1976, p.68).

According to S.R. REICE: "Spatial heterogeneity and **disturbance** are interdependent. **Disturbance** creates patches, but **patchiness** modifies and sets the extent of the **disturbance** – that is, the **disturbance** responds to the underlying heterogeneity of the **environment**. Different patch types generate different **frequencies** and degrees of **disturbance** and provide numerous opportunities for **recruitment**" (1994, p.434).

The whole subject is closely related to **percolation** and **criticality phenomena** in **composite systems**: **avalanches**, **flicker noise**, etc.

In a different meaning, M. MARUYAMA widely researched heterogeneity in cultures and states: "In any society, at any time there is heterogeneity of logics among individuals. It is possible to find individuals of any logical type in any culture at any time... Cultural differences consist in the way some logical type becomes dominant and influences individuals of other types. Beneath the homogeneous surface of a culture, there are all individual logical types, hidden, camouflaged or transformed" (1994, p.3).

As observed by MARUYAMA, heterogeneity is in some societies and cultures considered positive, and in others, negative. He argues that heterogeneity could "mean **interaction** for mutual benefit", a view held in some African cultures, as the MALINKE of Western Africa.

The use of the term "heterogeneous" seems subject to some misunderstandings. M. BUNGE writes: "There are no heterogeneous systems (e.g. systems composed of people and values, or books and theories)" (1993, p.214)

This should be correct if we would give to "heterogeneous" the **meaning** of "foreign to", or "not coherent with", or "without **structural** and **functional** relations". An hypothetical living being, constructed from **elements** and **organs** from different and unrelated animals would be heterogeneous in this sense... but could not function, nor survive.

1521

HETEROGENEITY and DECOUPLING^{1) - 2)}

The subdivision of a system into functional **subsystems** is useful in order to isolate the various **subsystems** from many disturbances.

Each **subsystem** must take charge only of some quite specific **disturbances**, related to its **function**, but protects the system as a **whole** against them with an enhanced efficacy.

Such a **decoupling** thus allows for a significant increase of the **global efficiency** of the system.

This acquired superiority of very **heterogeneous** systems over the less differentiated ones is generally obvious and explains possibly the universal trend towards the **emergence** of

more and more **complex systems**, whose **flexibility** and **adaptiveness** is considerably enhanced by heterogeneity. This applies equally to individual systems and to **populations**.

As noted by C. HOLLING, decoupled heterogeneity also enhances systems **resilience**. (1976, p.80-82).

1522

HETEROGENIZATION (Self-)⁴⁾

"The incorporation of many ways of living, working and thinking into yourself" (M. MARUYAMA, 1994, p.38)

MARUYAMA states: "It can occur in material, behavioral, psychological or logical areas. Everybody practises it, at least in the material sphere". He gives as an example, eating French, Italian or Chinese food, at times.

However, he adds: "But self-heterogenization in logics or **mindscapes** types occurs much less frequently" (Ibid).

This would cover the incorporation of different views or feelings in one's own **mindscape**, and could become indispensable for executives of multinational firms transferred from one country to another, whose culture is different.

1523

HETERONOMY^{1) - 2)}

"Condition of a system controlled from outside" (E. SCHWARZ – Glossary, 1993, p.7).

This condition is antinomic to **autonomy**. But of course, no system is either entirely **autonomous**, nor heteronomous. It is this last case, it would simply be a **part** of the **environment**.

1524

HETEROPOIETIC¹⁾

Characteristic of a system or **artefact** designed by men, with some **purpose**.

Heteropoietic systems have an **algorithmic** character, or in other words, they have a very limited **autonomy**, or none at all.

In particular, they are unable to maintain themselves or to modify spontaneously their **activity**. They need to be activated, steered and controlled from outside.

They are not **self-reproducing**, neither as a **whole**, nor as to their **components**. **Machines** in general are heteropoietic.

1525

HETEROSIS^{1) - 4)}

Superior qualities produced by the cross-breeding of different genetic lines in plants or animals.

R.L. MEIER tried to extend the **concept** to social sciences and in this case defined heterosis as "Hybrid vigor as a consequence of acculturative **processes**" (1961, p.110).

Such **processes** consist of "Selective combination of **elements** from both the cultures so that a distinct hybrid is formed, the most prominent example being that of England after the Norman invasion" (p.111).

The numerous challenges produced in *individuals* by a different **worldview** and the need to find adequate adaptive **responses** may be considered as the means for heterosis in clashing cultures.

The subject, unfortunately has not been much researched.

1526

HETEROSTASIS I ⁵⁾

"The artificially induced stimulation of the body **mechanisms**" (H. SELYE, 1975, p.467).

This is the original concept of SELYE, quite different from KLOPF's one (see hereafter).

SELYE explains: "Natural **homeostatic mechanisms** are usually sufficient to maintain the normal **state** of resistance. When faced with unusually heavy demands, however, ordinary **homeostasis** is not enough. The "thermostat of defense" must be raised to a higher **level**. For this **process**, I proposed the term *heterostasis* (from the Greek *heteros* = other) as the establishment of a new **steady state** by treatment with **agents** which stimulate the physiologic **adaptive mechanisms** through the development of normally dormant defensive tissue reactions. Both in **homeostasis** and in **heterostasis**, the *milieu interieur* participates actively" (p.86).

This biological **model** implying **cooperative** help by some outside **element** or system, could probably be translated to psychology and the social sciences (in **groups**, **organizations**, **enterprises**, and **cultures**) with quite more than an **analogical meaning**. Unfortunately, the subject seems to have been generally ignored.

1527

HETEROSTASIS II ^{1) - 2) - 5)}

The "maximal condition" that may be reached by a system (After A. Harry KLOPF, using the neuron as an example - 1972, p.5).

The author understands by "maximal condition" (of a neuron) the difference between "the amount of depolarization (pleasure) minus the amount of hyperpolarization (pain)". He explains: "The solution to the mind-body problem is an identity theory. A neuron undergoing depolarization *is* elementary pleasure; a neuron undergoing hyperpolarization *is* elementary pain. The subjective **event** of the experience of pleasure or pain is identical to the objective **event** of neurons undergoing depolarization or hyperpolarization, respectively" (p.6).

These thesis, quite **behavioristic** and **reductionist** and, besides, semantically expressed in a way contrary to the **non-identity principle**, should be closely scrutinized.

KLOPF generalizes his concept of heterostasis to the **set** of all **living** and **meta-living systems** and concludes his study with the following synthesis: "The evolutionary **process** has established an equivalence between that which has **survival** value and that which is a source of pleasure. Thus, **living systems**, in pursuing heterostasis, participate in three broad categories of actions:

1. self-preserving **behavior** (**maintenance of homeostasis**);
2. species-preserving **behavior** (reproduction);
3. **stimulation-preserving behavior** (**knowledge** acquisition and play).

Recognition that these **categories** represent **subgoals**, pursued only as means to an end (Heterostasis), renders certain aspects of human **behavior** more understandable" (p.64).

1528

HETEROSTAT ^{2) - 4) - 5)}

"A system that seeks (moves toward) a maximal condition while not necessarily ever achieving it" (H. KLOPF, 1972, p.9).

According to KLOPF: "The primary **goal** of animals, including man, is the achievement of a maximal condition (*of excitation*), not the achievement of a **steady-state** condition... The **variable** to be maximized is that of the amount of neural polarization being experienced (which is) defined to be equal to the amount of depolarization (pleasure) minus the amount of hyperpolarization (pain) (p.5)

The author adds the following comments: "Nervous systems are so structured that **homeostasis** is a necessary (but not sufficient) condition for the **maintenance of heterostasis**. This explains why **organisms** vigorously pursue **homeostasis** even while it is not their primary **goal**. That **homeostasis** is a **subgoal** suggests that **survival** may not be as central a concern of **living systems** as has been previously assumed" (p.5).

From a more general viewpoint he considers that "The nature of heterostats is such that they do not cooperate as **parts** of larger heterostatic systems unless they have more positive than negative **reinforcement** to do so" (p.57).

The present example of the difficult ordering of various supra-national systems seems to confirm KLOPF's opinion. It seems thus possible that the growing severity of global planetary **messes** may exert finally a favourable influence.

1529

HETEROSTAT (Elementary) ²⁾

A. Harry KLOPF describes as follows his concept of the "elementary heterostat": (a neuron, an individual in a society, and, generally an active **component** in a **complex system**, that may itself be considered a **homeostat**): "An elementary heterostat derives its power from the

special way in which it utilizes **feedback information**. In the case of **positive feedback** (for example, excitation delivered to a neuron), not only does the **input** enhance the **output** but also the **input enhances the effectiveness of recently active positive feedback loops**. In the case of **negative feedback** (for example **inhibition** delivered to a neuron), not only does the **input** diminish the **output** but also the **input enhances the effectiveness of recently active inhibitory feedback loops**.

In this way, the heterostat not only accomplishes **short-term** modifications in its **behavior** but it also accomplishes **long-term** modifications, thus encoding causal relations and providing a basis for intelligence" (1972, p.61-62).

1530

HEURISTICS ^{2) - 3)}

1. Any kind of conceptual device designed to think about a problem, to uncover so-called **facts**, to better understand **phenomena** and to accelerate the discovery of proofs and **laws**. (from the Greek "eurisko": I Found; famous through ARQUIMEDES' well known exclamation "Eurêka", I found out)

2. "Step-by-step procedures which in a finite number of steps insure that a satisfactory solution to the problem is reached" (J.van GIGCH, 1978, p.204).

van GIGCH compares **algorithms** and heuristics: "An **algorithm** guarantees that the optimum solution is reached. The heuristic leads to a satisfactory solution, not necessarily optimum. Both consist of a finite number of steps... It is important to note the difference between heuristics and **rules** of thumb. A **rule** of thumb usually has no analytical foundation and has been developed on the basis of **intuition** and long-time experience... Heuristics to replace them, will probably start from the **rule** of thumb and develop on the basis of a solid and rigorous analysis of the problem and the factors involved. Heuristics are **methods** "to reduce search" (p.205).

M. BODEN's opinion is different: "Most heuristics are pragmatismal rules-of-thumb, not surefire **methods** of proof. Although there is a reasonable chance that they will help you solve your **problem**, they can sometimes prevent you to do so" (1990, p.53).

Heuristics are used to explore a defined extension of possibilities within a **set** of **generative rules**, i.e. by defining a specific **search space** and **paths** of exploration.

M. BODEN gives as an example the **rules** of chess: "Here the **search space** consists of all the board **states** that could be reached by any series of legal moves. Each legal move involves a specific **action** defined by the **rules** of chess" (p.77).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

However, M. BODEN also observes: "It is one thing to say that people use heuristics to solve **problems**. It is another thing to say that all the challenges facing creative thinkers can be met by applying ordered heuristics to strictly defined **search trees**, in the way that traditional **A.I.** problem-solvers do" (p.111). Heuristics could thus be limitative to *very* original creative thinkers, whose **creativity** could be in producing wider embracing heuristics.

We may be led in this way to "... the need for heuristics for changing heuristics" (p.210).

An interesting generalization of heuristics has been proposed by D.B. LENAT in his program EURISKO (or AM). According to him the same exploration **process** can be used at successive **hierarchic levels** (p.211).

Heuristics include the discovery of satisfactory **rules of inference** and the **selection** of the shortest ones. It follows: "... mainly **intuitive**... principles and depends on the type of theory" (after the A.I. Dictionary of the "Österreichische Gesellschaft für **Artificial Intelligence**", p.15)

According to J.W. SUTHERLAND, "... many of the higher-order **paradigms** ... serve as heuristics, a priori '**masks**' we can wear to lend some tentative **order** to otherwise ill-structured (effectively indeterminate) **phenomena**. As opposed to a theory, per se, which depends for its utility on its apodictical quality (i.e., its ability to be empirically validated), the heuristic makes no pretense to rectitude or allegorical alignment with some specific real-world entity. Rather, it serves merely as a synthetic **construct** which is usually a combination of two distinct **components**:

"A *metatheoretical* component which serves to provide an initial and quite broad **boundary** for analysis...

"The second **component** of a proper heuristic is *algorithmic* in nature: it really involves the specification of the '**rules**' we will use in disciplining subsequent analysis, setting in the broadest way the **criteria** of investigation and **truth**" (1973, p.182-3).

In a quite different sense, statistical **correlations** between some **variables** can be used as a base to search for their significance, as shown by R. MARGALEF (1980, p.118). This could be called "statistical heuristics".

I.G. BLOOR describes the uses of heuristics in **decision-making processes**. He writes: "Two basic versions exist: one where the **method** is unknown or unstructured (**trial and error**) and the **objective** or end solution is fixed, and the other where the **method** is proven or known and the **goal** or solution is unknown... The technique may be used where source **data** do not easily fit into a mathematical or similar **model**" (1987, p.18).

1531

HEXAGONAL SPACE FILLING²⁾ - 4)

W. CHRISTALLER (1933) and A. LÖSCH (1945) gave numerous examples of a tendency to hexagonal occupation of the geographic **space**. As stated by M.L. WOLDENBERG: "These writers recognized that the most efficient shape in terms of accessibility to the center of an area is the circle. Circles, however, cannot be packed into a space without leaving interstices. Hexagons are the polygons which allows the closest packing in an area, consistent with minimizing movement **cost** to a point". Moreover "... the overlap between circles emanating from centers is a minimum for an hexagonal lattice of centers" (1969, p.24).

The existence of a mathematical **set** of the various possible types of **nested hexagonal hierarchies** in the occupancy of space has been demonstrated by LÖSCH. The nested **subsets** can be trapezia, pentagons or hexagons (*ibid.*, p.25).

Natural geographic irregularities may deform or even suppress the hexagonal space filling net, but it is striking to see that **dissipative structures** observed by BENARD and related to **energy** dissipation in **emergent systems** tend also to take hexagonal forms.

This is perfectly consistent with both classical and Prigoginian **thermodynamics**. As noted by C. JOSLYN, hexagonal packing "... can be shown to maximize ... **energy flow** and **thermodynamic entropy production**" (1991, p.641).

Either we witness a **dynamic equilibrium**, with stable hexagonal space filling (sustained by a **stable energy flow**), or observe the progressive **emergence** of a new **structure** as a result of the "flooding" of the system by massive and sustained **energy** supplements, which lead the system to a higher **level of organization**, i.e. of **entropy production**.

→ **Density of occupancy; Foraging theory; Isotropy; Substrate**

1532

HIERARCHIC LEVEL²⁾

A specified level in a vertical or tree-like **structure** or **organization**.

Any complex system is hierarchically organized, in correspondance with the **regulations** and **controls** of its various **functions**, which need to be coordinated and harmonized in order to secure the **survival** of the system.

Hierarchic levels would seem to have historically appeared first in **living systems**, but even possibly in prebiotic ones.

1533

HIERARCHIC MODELS VS. PARALLEL ONES²⁾

Since long time, and still on-going, there is a controversy between the proponents of hierarchic or parallel models or **organization**, in general.

A specific case, i.e. "**Cognitive systems architectures**" has been considered by Marta OLIVETTI BELARDINELLI (1998, p. 11-26). She advocates for an "**integration** of perspectives". Historically the hierarchic view has been dominant, at least in western thinking. This was probably a result of the search for short-cuts in the **management** of complex situations of all kinds, as the hierarchic ordering leads easily to unconscious or conscious **algorithms** of treatment ("Act according to the **rules** and so, avoid problems")

It should however be observed that:

1- Any hierarchical **order** has been constructed in a historical **dimension**

2- The hierarchical view, when strongly established, tends frequently to block needed **adaptation**

In turn the parallel way implies the possibility of unlimited **adaptability**. In OLIVETTI BELARDINELLI's words: "There maybe some justification for claiming the superiority of hierarchical structuring, which relies on **input-specific** systems with differentiated processing, interconnected according to a **structure** compatible with the classical architecture of the **nervous system**. However, the limitations imposed by this type of structure on the explanation of **adaptation processes** seem far more serious than those characteristic of **connectionism**, that is, regarding the **optimization** of **processes** as **complexity** increases"(p. 17)

In short, hierarchic structures and **models** could represent the more or less **periodic** summing-up of the stabilized results of adaptation processes through parallel **activity**.

→ **Bottom up; Parallel distributed processing; Top down**

1534

HIERARCHIC ORGANIZATION OF THE SYSTEM²⁾ - 4)

"The type of ordering in which individual **elements** of the system are systems of lower **order**, and/or the system under study appears as an **element** of a higher-order system" (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.55).

According to these authors: "Any given system can be adequately described provided it is regarded as an **element** of a larger system... The problem of presenting a given system as an **element** of a larger system can only be solved if this system is described as a system" (p.270).

The authors refer to this as the "paradox of hierarchy" and state that it "essentially represents a statement of **interdependence** of the solution of two problems: 1) the **description** of the system as such, and 2) the **description** of the system as an **element** of a larger system" (p.271).

This looks like a practical application of **GÖDEL's incompleteness theorem!**

These notions are however somewhat ambiguous and questionable, when applied to real **situations**. For example, many consider that the member countries of the European Community are the **subsystems**, while the real future functional **subsystems** of the E.C. (i.e. its supra-national institutions) are still a-building, a **process** in many cases obstructed by some national negotiators or pressure **groups**, generally representative of the national **subsystems** whose power would suffer limitations from the new community **subsystems** (see "**Hierarchic emergence**").

From a more formal viewpoint, as stated by G. KLIR "Hierarchical organizations are important not only for reducing descriptive **complexity** of systems, but they play also a significant role in reducing computational **complexity** of some systems problems... If the partitioning of hypotheses can be arranged hierarchically on several **levels**, the reduction of computational **complexity** may be phenomenal" (1993, p.49).

1535

HIERARCHIC STRUCTURE

→ **Structure (Hierarchic)**

1536

HIERARCHIC SYSTEM ^{1) - 2)}

"A system composed of **subsystems** that, in turn, have their own **subsystems**, and so on" (H. SIMON, 1958, p.64).

H. SIMON states: "By a hierarchic system, or hierarchy, I mean a system that is composed of interrelated **subsystems**, each of the latter being in turn hierarchic in **structure** until we reach some lowest **level** of elementary **subsystems**. In most systems in nature, it is somewhat arbitrary as to where we leave off, the partitioning and what **subsystems** we take as elementary" (Ibid).

SIMON notes how the physical **concept** of "elementary particle" has evolved within the two last generations. Other examples, biological or astronomical, show that an "elementary **subsystem**" is largely a matter of definition by the **modeller**.

He also stresses that the relations among **subsystems** are quite more complex than an univocal and common **dependence** from an upper **level** or rigid **control** over inferior **levels**.

Hierarchic systems are indeed made of co-regulated **subsystems** and a **meta-level's** role is (or should be) more of **regulation** and **cohesion** than of domination.

→ **HORA and TEMPUS parable**

1537

HIERARCHIES (Connexions between various types of) ^{1) - 2)}

B. WALLISER classifies hierarchies within four types (see infra: "**Hierarchies (Typology of)**")

According to him these "four types of hierarchies may be distinguished from each other in different ways:

- qualitative and **structural** hierarchies, are based on an **embedment** principle by which the higher **level objects** are the inferior **level sets**, while **functional** and genetic hierarchies are sequential, based on an influence principle, where the **objects** of the superior **level** are of the same nature as those of the inferior **level**;
- qualitative hierarchies include **objects** on a similarity base, which do not necessarily have direct relations (material or logical) amongst them, while the other hierarchies include **objects** which generally are strongly interactive because of their proximity or sequentiality;
- genetical hierarchies are explicitly related to a **diachronic** viewpoint and exist only because of this temporality, while the other hierarchies correspond to a **synchronic** vision and remain invariable during a given **period**, even in case dynamic **phenomena** take place within them" (1991, p.74).

He adds: "Some hierarchies may be superposed in the sense that, with a similar arborescent **structure** among **objects**, the relations may be understood in two different ways. Thus, the qualitative hierarchies coincide with the other ones if the **classification criteria** of the **objects** are precisely their membership of the same **set**, their functional **complementarity** or their common origin (for example: phylogenetic **classification** of animals). Likewise, **structural** and **functional** hierarchies merge when an integrated **subset** is "represented" by one of the **elements** which assume a leadership (as in an enterprise organizational chart). Finally, **functional** and genetical hierarchies fuse if the **objects** submitted to some other of superior **level** have been generated by it (parental authority in a family).

"Some hierarchies are also **embedded**, if the **objects** in some type of hierarchy are already hierarchies pertaining to some other type. It is thus possible to have a qualitative hierarchy which uses as **classification rule** for the **objects** the similarity of their hierarchical **structure**, of their hierarchical **regulation** (centralized or decentralized **organization**) or their hierarchical generation. It is likewise possible to find some **functional** hierarchy composed of

objects made of a **structural** hierarchy (f. ex. **regulations** in an oil refinery made of men and machines). Finally it is possible to observe some genetical hierarchy in which each generated **object** is in turn a **structural** or **functional** hierarchy (ontogenesis **process**)" (p.74).

1538

HIERARCHIES (Properties of) ²⁾

According to B. WALLISER: "The properties of hierarchies may be studied from three viewpoints:

"- their **organization** is arborescent, the **nodes** being formed from **homogeneous** or **heterogeneous objects** and the characteristic relations connect every **object**, in principle in an exclusive way, to some immediately superior **object**. Moreover the **tree** is generally characterized by its depth (number of **levels**) and its extension (average number of descendants per **object**);

"- their workings result of the **complementary** or alternative **behavior** of the different entities, and of the concrete **interactions** between **levels** (**interactions** of various types and **frequencies**). The global **structure** is sometimes related to some **environment**, itself hierarchical, with **communication** at each **level**;

"- their **evolution** includes the initial upbuilding which quite naturally takes place by successive **levels**, but also includes either the ulterior rebuilding related to the modular modification or replacement of the **elements**, or a **re-structuration** or reordering of the **network** of their **relations**" (1991, p.75).

1539

HIERARCHIES (TEMPORAL) ¹⁾²⁾

The general ordering of natural **phenomena** (but also probably of the social ones) seem to result of **trade-offs** between **rhythms** of different **periodicities**. B.T. WERNER writes: "Fast **variables** become slaved to low variables and lose their status as independent dynamical variables" (1999, p. 103)

This corresponds to **power laws** and to HAKEN's **slaving principle**.

1540

HIERARCHIES (Temporally embedded) ²⁾

B. WALLISER emphasizes the temporal aspect of hierarchies in evolving **situations**: "...the "temporally **embedded** hierarchies" offer **short, medium and long term phenomena**, defined by corresponding different velocities of variations: the slow **variable** "frames" the quick ones and these become "integrated" into the slow one" (1991, p. 75).

This is very significant, because it implies an integrated theory of **cycles**. See: "**KONDRA-TIEV cycle**".

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1541

HIERARCHIES (Typology of)^{1) - 2)}

B. WALLISER establishes in the following way a typology of hierarchies:

"- **Qualitative hierarchies** in which various **objects** are classified according to the similarity of their properties in some **homogeneous** subcategory, various of which become in turn grouped in a larger **category**. This leads from a particular **level** to a more general one through various steps, by way of a subdivision **link**.

"- **Structural hierarchies** in which various **objects** are collected according to their spatial proximity in some **homogeneous subset**, various of which become in turn integrated into a wider **set**. This leads from some micro-level to a macrolevel through various **strata**, by way of a subagency **link**.

"- **Functional hierarchies** in which various entities are submitted to the deciding authority of a superior **regulating** entity, various of which are themselves coordinated by a higher entity. This leads from an infra **level** to a supra **level** through various "**echelons**" by way of a subordination **link**.

"- **Genetic hierarchies** in which various entities come from an original common entity by temporal filiation, various of these latter themselves coming from an older one. This leads from a former to a later **level** through successive generations by way of a sequential **link** (1991, p.72-3).

WALLISER shows in his paper how these four basic types of hierarchies show up in the most varied systems and gives numerous examples.

1542

HIERARCHY^{1) - 2)}

An asymmetric vertical **order** in a system through which **elements** or **subsystems** of a lower **level** of **complexity** are regulated or controlled by one or several others of successively higher **level**.

The hierarchy **model** itself, as an **isomorphism**, generally pervades any specific hierarchized system, i.e. the **subsystems** themselves, down from **level** to **level**, are true to the hierarchical type.

M.D. MESAROVIC, D. MACKO and Y. TAKAHARA developed a general "Theory of Hierarchical, Multilevel Systems" (1970) in which they study the concept of hierarchy, the basic types of hierarchies, the **levels** of **complexity** and establish a mathematical theory of **coordination** in unconstrained or **constrained** systems. As stated by these authors: "The requirements for proper functioning of a system on any **stratum** appear as conditions of **constraints** on the **operation** on the lower **strata**" and "... for a proper functioning of the system on a given **stratum**, all the lower **strata** have to function correctly" (p.41).

According to J.C. LUGAN a **cybernetic** hierarchy of systems can be established wherein **information** rich systems tend to control **energy** rich ones (1993, p.46).

According to J.A. GOGUEN and F.J. VARELA: "The idea of hierarchy is often presented from the point of view of the **interdependence** of different **levels** of systems **descriptions**. Particular instances of hierarchical **structures** including **multilevel cooperation** can be found. GOGUEN presents a general theory of hierarchical systems of interdependent **processes**. Its basic ideas are **interconnection**, **behavior** and **level**, and its theoretical framework is categorical algebra" (1979, p.35).

The most obvious **function** of hierarchies is the **coordination** one, which is quite visible in **living systems**. However, in human **organizations** this **role** can be obscured when **coordination** is managed by ill-informed and authoritarian **controllers**. Another important **function** for the higher **strata** in hierarchies is **adaptation** and **creativity** in case of important **changes** in the **environment**.

From the basic viewpoint of the nature of hierarchy, and according to D. BOHM and F.D. PEAT it is a result of "... the **activity** of the generative principle within the **generative order**" (1987, p.164).

According to this view, hierarchy results of the progressive **morphogenesis** of **complexity**. Remains to be seen how this **generative order**, which seems to be at work in all **complex systems**, organizes **morphogenesis**.

A **complex system** generally shows various hierarchic **levels**, the lower ones being **embedded** into the higher ones. A. KOESTLER emphasized the "double-faced" aspect of **elements** in a hierarchy: they function as **wholes** in relation to lower **levels** and as **elements** of **wholes** at a higher **level**.

A good example of hierarchy is found in any complex **living system**, as shown by J. G. MILLER (1978).

The **concept** of hierarchy implies **asymmetric dependence** relations. It is in this sense that, as stated by D. WILSON, the taxonomic Linnean hierarchy is "... a system of **nested classes** whose members are individual **organisms**" (1969, p.4).

1543

HIERARCHY AS A NETWORK²⁾

B. WALLISER in no way opposes the **concepts** of hierarchy and network and he connects them in the following way:

"The notion of hierarchy evokes the image of an arborescent **structure** where various **objects** do have "vertical" relations, oriented toward an **object** on a superior **level**, various of these superior **objects** being in turn oriented toward another one, at a still superior **level**. It seems opposed to the image of a reticular **structure**, wherein **objects** have "horizontal"

relations, sometimes very intricate, where **loops** do appear in such a way that no precedences seem to exist. However, even in a hierarchy, **objects** which are connected to another one of superior **level**, may have direct relations with each other. The nature and intensity of these relations may even contribute to the definition of the successive **levels**" (1991, p.71).

St. BEER exemplifies such networks (which he calls "hierarchical stochastic networks", showing that they are more satisfactory **representations** of complex **organizations** that the classical "tree", because they show that hierarchic **levels** can be somewhat **fuzzy** and allow for some leeway in personal or institutional **relationships** (1968, p.194, fig.16).

1544

HIERARCHY (Classificational)²⁾

"A **function** which assigns to each **object** the appropriate **label**... from a **set** of **labels** (R.C. CONANT, 1974, p.9)

CONANT writes that each **label**: "...depends upon and carries **information** about the constellation of characteristics" and adds that: "To select the proper **label** the classificational hierarchy must be provided with $\log_2 N$ **bits** of **information**, on the average, about the characteristics of the **objects** (less if the **labels** are not equally probable)" (Ibid.).

1545

HIERARCHY (Distributive)²⁾⁴⁾⁵⁾

A multi-centered type of hierarchy that admits regional **dominance** around local centers.

This **model** comes from geography. It has been used for ex. for the study of AIDS propagation. If some **phenomenon** should diffuse from a unique center, such a **process** would be very slow. However a pathogen can easily "jump" from one point to another, sometimes very distant, and become there the focus of a new **diffusion** center.

The **model** is quite general and can be applied to the diffusion of a new **technology**, or of a new religious creed, or a forest fire, or a financial panic.

It is closely related to the **concepts** of **composite system** and **percolation**.

1546

HIERARCHY (Emergent)^{1) - 2) - 4)}

The **emergence** of a system of a superior **level** of **complexity** goes with a deep reshaping of the internal as well as reciprocal **organization** of the newly associating **components**. The following aspects are specially noteworthy:

1) the **components** lose a part of their **autonomy** when they enter in reciprocally conditioning **interrelations**;

2) their **control** over their own **elements** is somewhat reduced, specially when these **elements** start to participate as such in macro-interactions;

3) the new emerging **interrelations** require a **coordination** at their own **level**, which implies the shaping of a superior hierarchical **level**;

4) the **functions** of the **components** do not become the **functions** of the **emergent** system, which may need, demand or provoke their weakening or even their elimination;

5) certain constitutive **elements** of the **components** may escape from their **control** and integrate themselves directly to the **emergent functions** of the new system;

This type of **situations** is more common than generally believed.

The moulting **processes** that lead to the adult insect seem to be true to this **model**. It is also probably the case of embryonic reorganizations during the pregnancy and quite certainly of the present **emergence** of the supranational systems.

1547

HIERARCHY (General)²⁾

Prof. M. KALAJDIEVA (Institute of Control and Systems Research of Sofia, Bulgaria) proposed the following postulates for a general concept of hierarchy. she writes:

POSTULATES OF GENERAL HIERARCHIE

1. A general hierarchie GH is an *one-dimensionally orientated multi-dimensional structure* of constructs (structures), up to infinite-dimensional.

2. Each general hierarchie is represented by two coupled GHs – one GH with an *inverse general hierarchie* having exactly the same structure, but defined with the opposite orientation of its direction.

3. *Deadlocks* are tolerable within a GH, only if they can be represented as cycles *interruptible* at a defined place under defined conditions.

4. A theoretical contextual difference is made between *elements* and *nodes* of a hierarchie. Many methods of modeling GHs rely on this separation.

5. The nodes of a GH may have both multiple outgoing and in-going connections. This particular feature is *polyhierarchie*. A general hierarchie having the feature of polyhierarchie is called *polyhierarchie* GH or shortly – *polyhierarchie*.

6. A general hierarchie *need not be connected* in all its parts. The mutual belonging of several parts possess individual identic or similar contextual characteristics, stating that number of (dis)connected structures are (parts of) one and the same general hierarchie.

7. The contextual characteristic is called *invariant characteristic (IC)*. The contextual ICs are described (defined) in *natural language*; their variety is *unrestricted*. There are nine

primary ICs: *direction, aspect of decomposition, element, node, connection, (algorithm of, rules of) decomposition, polihierarchie, polythematics, measure*. They might be independent of one another or not depending on the context of GH design and analysis. Four secondary ICs are derived from the system of the primary nine *composition, inverse hierarchie, level and step*.

8. General hierarchie(ies) may be modified (re-arranged) by

a) *Operations* which build by construction set up an *algebra* in the special mathematical sense of this term. They are *addition, subtraction multiplication and division*. Basic elements of the algebra are of two kinds of bases:

- 1st order base of algebra containing constructs of 2 nodes bound with 1 connection (or 2 connections bound with 1 node);

- 2nd order base of the algebra containing constructs of 1 nodes, all its subnodes and bound with as many connections.

b) Altering the *values or meanings* of invariant characteristic(s). Such changes may also change the degree of abstractness of modeling complex objects in GH(s) or change the context of modelled constructs, e.g. for comparative study.

c) *Special operations* typical only for the set of general hierarchies and bound to the context of the GH(s): *normalize* GH(s) on one and the same level, *haul up* and *haul down* across level (steps).

1548

HIERARCHY (Law of Requisite)^{1) – 2)}

"The lack of regulatory capability of a single **regulator** can be compensated for, to some degree, by conceptualizing the **regulator** as a hierarchical **multilevel structure** system".

This law, thus formulated by G. KLIR (1991, p.183) is due to A. AULIN (1989). KLIR comments: "In general, the weaker the regulatory abilities of available **regulators**, the more hierarchy is needed to achieve the same regulatory **performance**, if it is possible at all" (Ibid).

AULIN's law should be pondered not only for *engineered regulators*, but also for natural ones. (See Ch. FRANÇOIS, 1983, on "**controls**"). We urgently need discovering the higher **level regulators** in **ecosystems** and **socio-systems**.

1549

HIERARCHY (Organic)²⁾

According to R.C. CONANT, this class of hierarchies: "... is meant to include all hierarchical **"organisms"**, in a broad sense, which have a dynamic, physical existence and for which the **concept of survival** (in the face of threats from the **environment**) is relevant"...

But "... 'conceptual' hierarchies such as **language** and music are not included" (1974, p.11).

1550

HIERARCHY Theory²⁾

At the 1998 Conference of ISSS in Atlanta, J.M. WILBY described as follows the state of the art in hierarchy theory: "(it) is one of several possible **systems approaches**...used in the study of **complexity**...in the observing of complex **situations**. The theory is systemic in itself, dealing with the **issues** central to systems science, e.g. the importance of the **observer**, and the **flows** of **matter, energy, and information** through systems".

Hierarchy theory has been applied in such diverse **fields** of study as ecology, biology, linguistics, business, philosophy, mathematics and physics" (1998 Abstracts, p. 190)

"...an ongoing research...aims to determine the utility and validity of hierarchy as a systems approach for: 1) the analysis of existing **complex systems** and problem situations; 2) the **planning** of interventions in existing complex situations, and 3) the **design** of future systems

"Outcomes of the overall research will include the construction of a set of principles for hierarchy theory, the evaluation and design for a **methodology** for hierarchy theory, and the critical **evaluation** of hierarchy theory..." (Ibid)

This research is going on at the Lincoln School of Management at the University of Lincolnshire and Humberside, U.K.

1551

HIPPOCAMPUS¹⁾⁵⁾

One of two ridges along each lateral ventricle of the **brain**.

Hippocampus is a part of the limbic system, which is the seat of emotions and manages them. It is essential for the creation of **long-term memory** through the establishment of so-called **mental maps**. It has been observed that the taxi-drivers in a great city have a particular development of the hippocampus. On the contrary, damage to the hippocampus leads to considerable spatial desorientation. It also impairs the acquisition of **short-term memory**.

It seems moreover that the passage from short-term to long-term memory is obtained by "replays" by the hippocampus (also during sleep) that finally "etch" the lived experiences deeper into the cortex (Rita CARTER, 1998)

The hippocampus is the bio-physiological **structure** basically responsible for the implicit memory, called "retention" by HUSSERL, that allows us to understand as integrated **whole** a sonata, for instance, or any other phenomenon extended in **time**.

→ **Brain (Triune)**

1552

HISTORICAL DETERMINISM^{1) - 3)}

The global influence of former **states** of a system on its present and future **states**.

This is not Marxian historical determinism.

Neither is it the rigorous **monocausal determinism** of classical mechanics, nor **statistical determinism**. It corresponds to BOLTZMANN's after-effects ("Nachwirkungen"), i.e. the **effects** of the accumulated and registered or recorded **events** in the past of the system.

However, in **complex systems** this kind of "memory" does not lead to strict determinism, but merely to **sensibility to initial conditions**. This in turn endows the system either with **ergodic behavior**, or with **chaotic** characteristics.

D. RUELLE writes: "I think that history systematically generates **events** that cannot be predicted and have important **long-term** consequences" (1981).

V. VOLTERRA, starting from BOLTZMANN's equations, showed that they implied "the **initial conditions** of the system, under the form of an integral (or more generally a function) which represented the whole **information** related to the past of the system, unlike the classical vectorial form that represented only the present **state**. In this way, the system was not anymore deterministic in a strict Laplacian sense: its present is not anymore sufficient to determine its **evolution**; which is determined by its past as a whole" (G. ISRAEL, 1992, p.268).

We thus have a historical systemic determinism, with precise and specific characteristics.

J. HOLLAND in turn, observes that: "... future **populations** can only develop via **reproduction** of individuals of the current population. In particular, the population must serve as a summary of observed sample values (**performances**)" (1992, p.13).

Of course, "populations" can be of very different types: biological individuals, genes, techniques, **bits of information**, **memes**, etc...

Thus, while **innovations** open new possible futures, they are possible only on the base of the "presently remembered" (or registered) past.

→ **Present (Everlasting); Time binding; Time perception**

1553

HISTORICAL DIMENSION in systems¹⁾

Any **nonlinear irreversible system** has its own history. This is a consequence, in I. PRIGOGINE words of: "...**symmetry breaking dissipative structures** in which the system has the "choice" between various possibilities. The type of initial **fluctuations** determines the specific **dissipative structure** which will be realized. Once realized this **dissipative structure** is stable against the type of **fluctuations** considered. Successions of **instabilities** of this type

may occur, involving a kind of primitive **memory** or, so to say, a historical dimension. The present **structure** of the system can only be understood in terms of the succession of **instabilities** through which it was originated" (1973, p.71). Thus, wide **fluctuations** and the resulting **bifurcations**: "... introduce in a sense "history" in physics" (1978, p.46).

This is also explained in the following way by G. NICOLIS; "A **bifurcation** is really a moment when a **decision** is taken as... the system is confronted with multiple **choices**. It thus becomes sensible to **random effects** that, by way of statistical **fluctuations**, will finally favour one of the accessible **states**. Once channelled on one specific branch of **states**, the system will follow a course closely determined by this **critical choice**. In some sense, it then becomes a *historical object*, which will forever keep the record of former **events** that prevailed at the successive **bifurcation** points encountered. In sum, in addition to **deterministic elements**, **concepts** like **randomness** and history play a primordial role in **evolution**" (1984, p.12).

NICOLIS calls this "the insertion of **time** within **matter**" (Ibid).

1554

HISTORICITY¹⁾

A basic characteristic of any system as evolving in **time**.

Historicity is now firmly established as a systemic **process**. It has been confirmed by the Prigoginian **dissipative structuration model** as well as by the **deterministic chaos** one. The latter insists on the importance of a very precise - and quite difficult to obtain - good **knowledge** of the **initial conditions** and their ulterior evolutive **transformations**.

On the other hand, **sensibility to initial conditions**, as a basic characteristic of **deterministic chaos**, results in a new understanding of **irreversibility**, because it introduces the need for a better knowledge of the past of any system.

1555

HISTORIOGRAPHY: a critical view¹⁾²⁾⁴⁾⁵⁾

"The narration of a series of socially significant **events**". (A FUENMAYOR and R. FUENMAYOR, 1999, p. 69)

These authors - adscribed to **Interpretive Systemology** (University of Los Andes, Mérida, Venezuela) add "... significant according to certain more or less hidden **criteria**- among which a pseudo-causal thread is strung (the thread corresponds to the criteria which makes the events significant)".

They explain this disquieting comments as follows: "Historiography assumes that the **sequence of events** occurs on a culturally fixed stage. Thereby, historiography disregards that the events are what they are in terms of the cultural **context** that gives them **meaning**...

"The historical question is not simply: "Which events have led us to the present?" but, "What has been the series of cultural **contents** (which have made what has happened significant) that have led us to experience reality (including **history**) in the way we do at present?"

"Our history -ours, as a particular society- is not simply the history of the events in which our forefathers participated, but the history of how we come to appreciate **reality** and transform it (and both appreciation and **transformation**-are inseparable) in the manner we do today. It is the history of how we arrived at that cultural context that we now wish to impose on past events".

This is of course why history is rewritten by each generation and also written differently in different places.

However, in such **interpretive systemologic** terms, this sinks history into irremediable relativism. While this must certainly be taken into account, different insights in systemic terms seem possible, at a **meta-level** critique and also using **systemic models**, as for example **autopoietic social reproduction**, **dissipative structuration** and **emergence**, **dynamic stability** and the like.

As to the marxist view of **historical determinism**, it could probably be usefully reconsidered in the light of **thermodynamics** of **dissipative structuration**.

Two different- but closely interdependent- **processes** became active during the 19th and 20th centuries.

The first one was the ever more massive injection of **energy** (mainly fossil) in the **production process**. This trend became first active in England. Later on it propagated to Western Europe, and finally to the whole world (a process still running its full course presently)

The second one, i.e. technological **progress**, entered in a **positive feedback loop** with the first one. In fact, most of the present artificial devices are depending on the more or less massive use of energy. They were translated from laboratories to fields and factories only when they become efficiently amplified by a suitable energy **source**.

The whole process became mirrored in the **emergence** of a generalized societal structuration, unavoidably needed for practical use. Impressive examples are the material, informative, professional, bureaucratic and legal superstructures that made possible the massive use of the motorcar and the aircraft.

The global **sociosphere** in the making would have been impossible without the simultaneous (and even previous) development of the **technosphere**. The way this latter did build up- and specially the capitalistic (and later on the state-controlled) **concentration** of production tools was a more or less unavoidable consequence of the progressive construction of a close-knited technosphere.

→ **Historical determinism; Historical dimension in systems; History (Systemic); Saint Mathews principle**

1556

HISTORY DETERMINED ¹⁾

"Attribute of systems whose **behavior** is specified or can be understood better by looking into their past history" (K. KRIPPENDORFF, 1986, p.35).

According to KRIPPENDORFF: "In contrast to **state determined** systems, **predictability** of the future **states** of such systems improves when relying not only on their current **state**, but on a finite **sequence** of **states** preceeding it" (Ibid). He notes the relation to "higher-than-first-order **Markov chains**" and argues "that all history determined systems are incompletely observed **state determined** systems and that the recourse to history has **heuristic** value" (Ibid).

1557

HISTORY (Systemic) ^{1) - 3)}

L.von BERTALANFFY expressed his belief in the possibility of theoretical history: "Sociology is essentially concerned with a temporal cross-section as human societies are; history with the "longitudinal" study how societies become and develop... It seems history can learn from the system theorists, not ultimate solutions but a sounder methodological outlook... The construction of conceptual **models** in history is not only permissible but, as a matter of fact, is at the basis of any historical interpretation as distinguished from mere enumeration of **data**, i.e. chronicle or annals" (1962, p.15).

However, historic systems (i.e. human **groups** in general, states, cultures) are **nonlinear** in their **evolution**, and thus both globally **deterministic** and, at critical moments, probabilistic. Thus, merely **homeostatic models** would be insufficient and, in many cases, downright unsatisfying. S. GOONATILAKE, following P.M. ALLEN, sees history as a sequence of **bifurcations**. (1991, p.162).

Indeed, as stated by L. D. KIEL: "(In) human history... in many cases, the most significant **events** were those when existing **symmetries** dissolved and were replaced by new **patterns** of **interaction** and modes of **organization**" (1993, p.35).

The obvious and progressive acceleration of history (emphasized and thoroughly investigated by F. MEYER, 1954) seems to be related to the also progressive acceleration of the use of **energy**, which – after a slow **growth** since the paleolithic era – took an exponential **rhythm** since the 18th Century. It is thus a **thermodynamic process** of **dissipative structuration** in a **system far-from-equilibrium**, submitted to wild **fluctuations**.

This compiler believes that history needs a general **model** applicable to any human organized congeries and to their **transformations** through **time**. (Ch. FRANÇOIS, 1986 – See "**Socio-historical system**").

From another viewpoint, systemic history could become a useful tool for **sociognosis**, i.e. a better self-understanding of societies- a kind of collective consensual and Socratic "gnôti seauton", analogical to **autognosis**.

Some specific difficulties should however be considered. Each historian has his own **reference frame**, related to his cultural surroundings. IBN KHALDUN for ex., had necessarily as a 14th Century moslem historian, an approach and worldview very different from A. TOYNBEE or F. BRAUDEL in the 20th Century.

As a result, even if **methodology** could become definitively established, for example in systemic terms, every generation within every **culture** will easily want to revise past history in its own terms.

History tends to develop as a succession of evolving **interpretations**. This is a kind of extension of DILTHEY's "Entwicklungsgeschichte" ("developmental history"), as applied to philosophy (1922-1938), sections xvii-xviii)

Moreover, specific interpretations of history in a culture tend to become **autopoietic** in that culture.

1558

HOG CYCLE

A succession of more or less **periodic** gluts and shortages triggered by unrealistic **forecastings** based on spurious **extrapolations** (of the type "more of the same")

The expression alludes to the known fact that, if there are few hogs (or any other commodity) on the market, they will fetch a high price.

This will induce many farmers to breed hogs, which results in a future glut of hogs and, inevitably, in a crash of their sales value.

"Extrapolating from the present, (farmers) get the future wrong" (Economist 23.03.96, p.13)

The hog cycle is a good example of a **forecasting** trap.

Extrapolation from a **short term trend** is practically always wrong, because there are longer **trends** that supersede the shorter one. However, as this can also be true of the longer **trends** themselves, even the anticyclic view does not offer a very high degree of **probability**, and still less any certainty.

1559

HOLARCHY ¹⁾⁴⁾

"A **behavior** that is partly a **function** of individual nature and partly a function of the nature of the **embedding system**" (K. BAUSCH- Glossary- Pers.comm., 2002)

A hierarchized (i.e. **multi-level**) system with a number of **components** at each level, connected with components of the upper and lower levels.

The term was introduced by KOESTLER (1969, 1978)

Holarchies are characterized by the **embedding** (or embedment) of groups of elements at a superior level, where they are considered as individual **elements**, or **subsystems** in relation to a still higher embracing **level**. They can be representd as inverted trees, generally with a **fractal** architecture.

The holarchic **model** applies to biological and **social systems**, but not to **congeries**, nor in general to **colonial systems**, to composite systems affected by critical episodes, or to **ecosystems**.

A Csanyi's **zero-system** may become holarchical when stabilized.

In a recent paper, F. PICHLER elaborated on the holarchical model corresponding to "self-regulating open **hierarchic order**"(SOHO), using it in relation to **multi-agents systems**, that can be considered on their way to become holarchic. (2000, p. 80-84)

The **concept** seems to be more meaningful for **groups** and societies than for individuals. Any human group must adapt to specific environmental conditions and consequently develops a behavior adequate at the same time to its necessities and to the **constraints** of its **environment**.

This is why some authors have written about "islands cultures", "cultures of rice", "desert cultures", etc.

In such cases any individual behavior remains circumscribed within the general behavioral **rules** of the **whole** group.

The concept could also possibly be used for more specific groups: each enterprise, or administrative service, or even sport or entertainment groups seem to develop this type of behavior.

→ **Holon**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1560

HOLISM^{1) - 3)}

"A descriptive and investigative **strategy** which seeks to find the smallest number of explanatory principles by paying careful attention to the **emergent** properties of the **whole**, as opposed to the **behavior** of the isolated **parts**, as chosen by the **observer** in a **reductionist** strategy" (T.F.H. ALLEN & T.B. STARR, 1982, p.270).

The term and the **concept** were introduced in 1926 by the South African general and statesman Jan SMUTS. The term was derived from the Greek: "holos" = **whole**.

SMUTS wrote: "The idea of **wholes** and **wholeness** should... not be confined to the biological domain: it covers both inorganic substances and the highest manifestations of the human spirit. Taking a plant or an animal as a type of a **whole**, we notice the fundamental holistic character as a unity of **parts** which is so close and intense as to be more than the sum of its **parts**; which not only gives a particular conformation or **structure** to the **parts**, but so relates and determines them in their synthesis that their **functions** are altered; the synthesis affects and determines the **parts**, so that they **function** towards the **whole**; and the **whole** and the **parts** therefore reciprocally influence and determine each other, and appear to merge more or less their individual characters: the **whole** is in the **parts** and the **parts** are in the **whole**, and this synthesis of **whole** and **parts** is reflected in the holistic character of the **functions** of the **parts** as well as of the **whole**" (1926-1973, p.86).

M. BUNGE describes as follows the characteristic theses of holism, "the **ontological** view that stresses the integrity of systems at the expense of their **components** and the mutual **actions** among them":

"1. The **whole** precedes its **parts**.

"2. The **whole** acts on its **parts**.

"3. The **whole** is more than the sum of its **parts**.

"4. **Wholes** emerge under the **action** of **agents** that transcend both the **actions** among the **components** and the **environmental** influences.

"5. Totalities cannot be explained by analysis: they are irrational.

"6. The **whole** is better than any of its **parts**" (1979, p.39-40).

BUNGE sharply criticizes these thesis, reproduced however by him in a somewhat caricatural form (see hereafter)

According to ALLEN and STARR, both holism and **reductionism** seek to explain **emergent behavior** by invoking a lower **level** of **organization** (p.270).

Thus, both **strategies** admit the existence of **hierarchies** in systems.

J.A. GOGUEN and F.J. VARELA however observe: "Most discussions place holism/**reductionism** in polar opposition. This seems to stem from the historical split between empirical sciences viewed as mainly **reductionist** or analytic, and the (European) schools of philosophy and social sciences that grope toward a **dynamics** of totalities" (1979, p.40).

However: "It seems that both these directions of analysis always coexist, either implicitly or explicitly, because these descriptive **levels** are mutually interdependent for the **observer**. We cannot conceive of **components** if there is no system from which they are abstracted, and there cannot be a **whole** unless there are constitutive **elements**" (p.41).

These authors give the excellent example of harmony and melody, which are at "... a **level** of **organization** above that of the notes themselves" (ibid).

Finally: "**Reductionism** implies attention to a lower **level**, while holism implies attention to a higher **level**. These are intertwined in any satisfactory **description**; and each entails some loss relative to our cognitive preferences, as well as some gain" (p.42).

M. BUNGE holds a dim view on holism, which he carefully distinguishes from **systemics**, as holism "recognizes the existence of systems with specific characters (**emergent** properties), but treats them as totalities or **black boxes**". According to him holism "... refuses to analyse them and to explain the formation and the **collapse** of **wholes** in function of their **components** and the **interactions** between them" (1995, p.16). He also indicts holism as "responsible for the backwardness of the non-physical sciences. It has contributed precious little to serious systemics, precisely because: (a) it has not engaged in the study of the links that hold any system together, and (b) rather than constructing conceptual systems (theories) to account for **concrete systems**, it has spent itself in attacking analytical or atomistic approach and praising totality as such. Whatever **truth** there is in holism - namely that there are totalities, that they have properties of their own, and they should be treated as **wholes** - is contained in systemism, or the philosophy underpinning systemics" (p.410).

The most equilibrated view has been offered by G. KLIR who considers that present systems thinking: "... represents a synthesis of the **reductionistic** thesis and the holistic antithesis" (1993, p.36).

The French philosopher B. PASCAL anticipated (1670!) this view: "I consider impossible to obtain **knowledge** of the **parts** without knowing the **whole**, nor to know the **whole** without particular **knowledge** of the **parts**" (Quoted by R. VALLÉE, 1995, p.11).

The concept of **Gestalt**, as referring to the **perception** of **wholes**, also is another conspicuous root of holism.

Some view holism itself as a kind of **reductionism**. K. BAUSCH for ex. defines it as "A reductionist descriptive and investigative strategy for generating explanatory principles of **whole** systems" (Glossary, Pers.comm., 2002)

Indeed: "Attention is focused on the **emergent** properties of the whole rather than on the **behavior** of the isolates **parts**" (ibid).

Of course, holistic models should be paired with classical reductionist ones as both aspects are complementary and necessary for comprehensive **explanations**.

As a very simple illustration, while H₂O has specific properties as a whole, its constitution can be understood only by knowing the chemical and physical characteristics of H and O that allow them to combine.

1561

HOLISM (Law of Requisite)¹⁾²⁾

M. MULEJ and S. KAJZER introduced the Law of Requisite Holism in 1998 (see T. ECIMOVIC et al., 2002)

The Law "demands the author/s of the definition of a system representing the **object** under their consideration and/or **control** to clearly state what part of **attributes** of the object is included into his/her/their system, being the mental picture of the object under consideration and/or control" (2002, sect. 4.1)

The authors add: "He/she/they must do his/her/their best to fight oversimplification as well as too much **complexity** and complication, by using all available **knowledge** and **skills** as well as by **ethics** of **interdependence**" (ibid)

This means that the holistic **model** must not leave anything significant outside, nor overburden the model with irrelevant **elements**.

Of course, the crux of the matter are the **criteria** to be used to focus the holistic model in this way. Moreover, a very serious problem is that the **modeller** may easily be unaware of the insufficiency of his/her knowledge or may hold a prejudiced view. The authors explains possible ways to produce a holistic model that be satisfactorily focused, covering the **issue** as a **whole** and including all significant **relationships**.

Other authors, as for example J. WARFIELD and R. CARDENAS, or H. LINSTONE and I. MITROFF, and J. GHARAJEDAGHI have contributed interesting **methodologies** that should be used to construct models in accordance with the Law of Requisite Holism.

→ **Generic design; Unbounded Systems Thinking; Underconceptualization**

1562

HOLISTIC APPROACH^{1) - 3)}

"The view that an integrated **whole** has reality independent of and greater than its **parts**" (UNESCO, 1986, p.5).

"Independent" should be replaced by "distinct" in order to take BUNGE's objection into account.

The UNESCO – UNEP "Glossary of environmental education terms" comments that: "... the **environment** can only be understood by viewing it as a general complex of its **parts**" and that this can be done by way of a "thorough and comprehensive analysis of **interrelations** between the natural **environment**, social, cultural, technological and other factors" (p.5).

This applies obviously to any kind of **environment**, and must be extended to the system considered *and* its **interactions** with its specific **environment**. But it is in no way contradictory to more specific and precise research in some areas, provide both **viewpoints** become correlated.

1563

HOLOGRAM⁵⁾

A photography including diffraction **patterns** from which a three-dimensional image can be obtained.

Holograms are recorded by using lasers on photographic plates. "Holos" is the Greek equivalent for "**Whole**". As the Greek root "gram" means "write", then hologram, in D. BOHM words is thus "an instrument that "writes the **whole**" (1980, p.145).

Taking **dynamics** into account, BOHM describes the global **universe** as a "holomovement". This would give a kind of temporal dimension to some **objects** containing still traces of their past. Compare with "**aura**" and "**homeokinesis**".

Indeed, as stated by R. ROSEN: "In the hologram,... every point of the hologram contains **information** about *every* point of the **object**, so that the ripping a piece out of a hologram causes at worst a blurring or loss of **resolution**, but not the irretrievable loss of **information** pertaining to the **object**... For this reason, holograms are in fashion nowadays as **brain model paradigms**" (1974, p.173).

S. GOONATILAKE observes: "Using... holograms in three dimensions, enormous **interconnections** are possible. A cubic-centimetre hologram would allow for a trillion (10^{18}) **connections** alone, by interconnecting a million optical **elements**" Moreover: "Volume for volume the hologram therefore has an **interconnection** potential 100.000 times that of the **brain**. It appears that neural **connectionist** architecture using optical technology will not only increasingly dominate the future, but has the potential for reaching, if not surpassing, biological devices" (1991, p.110).

The holographic **analogy** is usefully applied to any system in which **parts** contain general **information** about the system as a **whole**. Possible examples are the **brain** and the administrative **organization**.

1564

HOLOGRAM (Non-local Quantum)¹⁾²⁾³⁾

This still very enigmatic concept- at least for this editor- has been discussed by E. MITCHELL (2000, p. 295-310) and a number of authors quoted in MITCHELL's bibliography (Ibid. p. 310-12), mainly since 1992.

Non-locality seems to imply a general sub-atomic cosmic **organization**, that could be a kind of **hologram**.

Self similarity could be distributed at the different **levels** of cosmic organization and manifest a global property (or global properties) also present at the quantum level and in our **brains** through quanta **processes**.

This would be the summing-up of basic **hologologies** between **levels**, as revealed by **WEIRSTRASS self-similar renormalization equation** and **fractals**.

This would imply a permanent **trade-off** in-between **bottom-up** and **top-down processes**, also at work in our ways of **perception**, **representations** and **understanding** of "**reality**", whatever this ambiguous term may mean.

MITCHELL writes: "Non-local **information** can now be seen as a ubiquitous and useful property of the cosmos rather than a unique **attribute** of particles (and human animals)"(2000, p. 298). This could possibly explain how we become able to construct **information spaces** (GERNERT, 2000, p. 255) more or less elaborated in accordance to our cerebral competence. It seems also to be compatible with MATURANA'S behavioral theory of **auto-poietic knowledge**.

The non-local hologram could also possibly bridge the temporal **dimension**.

All in all, the subject is fascinating and evokes many sidelines, but needs surely much more experimental work (in physics, and in **brain** research: for instance) and conceptual creation (without indulging in excessive **metaphorical** or empty **abstractions**)

Quantum holograms could also, according to MITCHELL, provide a scientific ground for parapsychology.

1565

HOLOGRAPHY as a metaphor³⁾

A way to represent a **whole** as a **network** of **connected** and more or less **redundant elements**, allowing simultaneously for specialization and a global **coherent behavior**.

The **brain** is now widely supposed to have an holographic **organization**.

A. HAUAN, J.A. JOHANNESSEN and J. OLAISEN characterize this **metaphor** as follows: "... the **whole** is enclosed in its **parts**: More specifically, if a holographic picture is broken into pieces, any single piece, when enlarged, will display all images of the original picture, al-

though maybe somewhat blurred. As a consequence, the "**whole**" could conceivably be reconstructed through a thorough analysis of any of the constituents **parts**" (1992, p.1057).

The **metaphor** implies that, within a system, any **element** should have (and in biological and cultural system, *have* indeed, as genes, **memes**, or **mindscapes**) at least a kind of historical imprint of the global **identity** of the system.

The holographic metaphor is as old as 19th Century's Arnold BÖCKLIN's "Public opinion" engraving that shows a gigantic dragon made of a multitude of similar dragonlets collectively **self-organized** in the suited way to ensure **self-similarity** between the micro- and the macro **level**.

1566

HOLOMOVEMENT²⁾³⁾

"A global and perpetual enfolding-unfolding dynamical dialogue where everything is connected to everything" (E. SCHWARZ's **explanation** of D. BOHM's **concept**)(1999, p. 140)

This somewhat ghostly global **model** of **reality** is tempered by the following comment: "In some instances, particularly at our normal **scale** of functioning (**mesoscale**), the holomovement may constitute relatively autonomous sub-**totalities** like the **objects** around us. In that case the usual way of considering separated objects interacting through external forces is a sufficient approximation (Ibid)

And "In the extreme case of non-**separability**, only the **whole** is true. There exist intermediate cases, like in particle physics experiments, where the **implicate order** can manifest itself by non-separable and non-local **effects**. For example, the particle-wave **duality** which appears as a paradox in the conventional interpretation of **quantum** mechanics, become limpid in the implicate-explicate model: the localized manifestations (quanta) belong to the **space-time** explicate order, whereas the wave-like effects are **reflections** of the **holistic** non-separable non-local implicate order. The wave or particle problem becomes the wave and particle double sided reality"

"Several other dilemmas, like **continuity/discontinuity**, **causality/non-causality**, **order/disorder**, **being/becoming**, **observer/observed**, mind/body, can be made intelligible with the double order model"(Ibid, p. 141)

Remains to find the **epistemologic** value of this model (What does it say about the ways of our **understanding**). And in the view of this editor, **ontological skepticism** is not eliminated by this mind-stretching **Weltanschauung**.

What would EINSTEIN have said? He, who did not believe in "spooky action at a distance"

→ **Reframing**

1567

HOLON ¹⁾ – 2) – 3)

"Any stable biological or social sub-whole which displays **rule**-governed **behaviour** and/or structural **Gestalt**-constancy" (A. KOESTLER, 1969, p.211).

KOESTLER gives the following explanations:

"1.1 The **organism** in its structural aspect is not an **aggregation** of elementary **parts**, and its functional aspects not a chain of elementary units of **behaviour**"

"1.2. The **organism** is to be regarded as a multi-levelled **hierarchy** of semi-**autonomous** sub-wholes, branching into sub-wholes of a lower **order** and so on. Sub-wholes on any **level** of the **hierarchy** are referred to as *holons*."

"1.3. **Parts** and **wholes** in an absolute sense do not exist in the domains of life. The *concept* of the **holon** is intended to reconcile the atomistic and holistic approach."

"1.4. Biological holons are **self-regulating open systems** which display both the **autonomous** properties of **wholes** and the dependent properties of **parts**. This **dichotomy** is present on every **level** of every type of **hierarchic organization**, and is referred to as the "Janus phenomenon".

"2.1 **Hierarchies** are "dissectible" into their constituent branches, on which the holons form the **nodes**; the branching lines represent the **channels of communication and control**."

"2.2 The number of **levels** which a **hierarchy** comprises is a measure of its "depth", and the number of holons on any given **level** is called its "**span**" (SIMON).

"3.1. Functional holons are governed by fixed **sets of rules** and display more or less flexible **strategies**."

"3.2. The **rules** – referred to as the system's *canon* – determine its **invariant** properties, its **structural configuration** and/or **functional patterns** (Ibid).

(For many more details, see reference)

The concept of "holon" has been sometimes misinterpreted, which led to unnecessary controversy. The holon is more than the sum of its **parts** because it includes the **interrelations** among these. But it is also less than this sum, because by entering in combination the **elements** lose some of their individual properties (or at least, they remain virtual and occult until the holon is destroyed). In order to make the point clearer, G. WEINBERG (1975, p.43) proposed the two following and somewhat paradoxically *complementary laws*:

"Composition Law:

The **whole** is more than the sum of its **parts**

"Decomposition Law:

The **part** is more than a fraction of the **whole**"

1568

HOLONOMY and HETERONOMY ¹⁾ – 3)

Holonomy is "the law of the **whole**". (→ "**Heteronomy**".)

D. BOHM writes: "Holonomy does not totally deny the relevance of **analysis**... Indeed, 'the law of the **whole**' will generally include the possibility of describing the 'loosening' of aspects from each other, so that they will be relatively **autonomous** in limited **contexts** (as well as the possibility of describing the **interactions** of those aspects in a system of **heteronomy**). However, any form of relative **autonomy** (and **heteronomy**) is ultimately limited by holonomy, so that in a broad enough **context** such forms are seen to be merely aspects, reelevated in the holomovement, rather than disjoint and separately existent things in **interaction**" (1980, p.156-7).

The perspective is finally neither **top-down**, nor **bottom-up**.

D. Mc NEIL insists that a **General Theory of Systems** should be holonomic, "i.e... contain a complete **representation** of itself, regardless of the **echelon** of **order** at which it is applied; for example, all of the central aspects of a **general theory of systems** must be represented in every subatomic system, mechanical system, social system, cosmological system, and every system in between. It must be **self-referential**, applicable to itself, and protean, able to change its own **form**" (1993, p.9).

While this author gives some interesting examples of such aspects, as for instance "**toroids**" and "**fluxes**", this remains still quite a tall order. One also wonders how this could be possible, in accordance with **GÖDEL'S incompleteness**.

The protean character however seems to exist, e.g. the various general formulation of the general theory: for instance SABELLI's **theory of processes**; HAKEN's **Synergetics**; PRIGOGINE's "total" **thermodynamics**; D. Mc NEIL's own's **dynamic systemology**; J.L.LE MOIGNE "**Système Général**" and others, less embracing.

1569

HOMEBOX ⁵⁾

A set of ordered and interacting **segmentation** genes which commands the also ordered **differentiation** and **development** of animals.

Such genes are called homoetic because each one is associated with some specific way of biological **structuration**, as for example producing a leg.

Homeoboxes are a very general feature of biological **organization**, from small invertebrates to insects and vertebrates, conveying a quite similar basic plan. They provide potential **positional information**.

Stephen DAY writes: "The amount of **positional information** builds up during the **development** of the **embryo**. Eventually the positional information is so complex that very small groups of **cells**, destined to become a particular part of the body, can be distinguished" (1999, p.4)

The homeobox is thus a basic "social **organizer**" proper to complex biological systems. A parallelism with **pheromones** in insect societies and **values** in human societies could be usefully researched.

Note: Some authors write "Homoeobox" in lieu of "homeobox" or "homeobox"

Homeoboxes, as specific ordered sequences of bases in developmental genes sequences, are now being closely studied (E. H. DAVIDSON & al, 1995).

It would be interesting to try to investigate the possible uses of this **model** to study psycho-sociological **constraints** in the **growth** and **stabilization** of all kind of societies, including the human ones.

→ **Regulation (Developmental)**

1570

HOMEBOX COMPLEX ⁵⁾

A distinctive DNA segment, consisting of some 60 amino acids, which is used by some group of genes to determine the basic body plan of a living **organism** (adapted from P. CORNING, 1988 b, p. 10).

The homeobox is a very archaic biological feature that has been conserved through the whole of **evolution**. It is present in the fruit fly (*Drosophila*) as well as in the human being.

According to CORNING it is "a microscopic example of a combination of labor that is oriented to the production of a combined emergent result" (See also De Robertis et al, 1990)

It is thus, from the systemic viewpoint, also an example of **emergence** of **complexity** through **synergy**.

The human genome research is of course closely related to the practical significance of the Homeobox Complex.

1571

HOMEOKINESIS ¹⁾ – 2) – 4)

The persistence of **coherence** among the **elements** of a system through its **transformations**.

D. Mc NEIL, who introduces the concept (pers. comm.), gives as an example the **transformations** of a hurricane whose "shape persists as a **stasis** amidst **flux**... despite continual transfusions, diffusions and exchanges of its substance, retaining its **identity**, regardless of whether its constituent molecules remain the same". Another example is a tree, or indeed any living being.

It seems to correspond to the **organizational closure** property in **autopoietic systems**.

Homeokinesis may also characterize the slow, but coherent historical **transformations** of natural **languages**, and even possibly of systems of **meanings**, **values** and **norms** in cultures.

1572

HOMEOMORPHISM²⁾

"The **transformation** between two geometrical figures A and B such that there is a continuous one-one correspondence *in both directions* between each point of A and a matching point of B" (T.A. & W. MILLINGTON, 1966, p.237).

This is the basic **topological transformation**, which is also very significant in **chaos theory**.

(Not to be confused with "Homomorphism" – see hereafter)

1573

HOMEORHESIS^{1) – 2)}

The condition of a **flow process** which remains canalised within **limits** in a growing system.

This neologism was created by C. WADDINGTON who explains: "Whereas the **process** of keeping something at a stable, or stationary **value** is called **homeostasis**, ensuring the continuation of a given type of **change** it is called **homeorhesis**" (1976, p.140).

In E. JANTSCH terms: "Homeorhesis ... (characterizes) the preservation, not of a **stationary state** (as in **homeostasis**), but of a **flow process**. **Disturbances** are counteracted so as to bring back the **process** not to where it was when disturbed, but to where it would have progressed if left undisturbed. Many biological and social **growth processes** are homeorhetic" (1975, p.92).

Growth of a system is normally homeorhetic, because it is the only way to maintain its identity. The system turns **homeostatic** (i.e. acquires **dynamic stability**) when it reaches its full **development**, in accordance with its **archetype**.

1574

HOMEOSTASIS^{1) – 2) – 4)}

The capacity of a system to maintain its **morphology**, its functionality and **internal states** at some definite **level** through **fluctuations** within established maxima and minima, in spite of changing external conditions.

Under the heading "**Constancy** of internal milieu", P. VENDRYES writes: "The coupling of **storage** and **control** has immense consequences for physiology, for through these mechanisms an **organism** maintains the **constancy** of its internal milieu. This happens despite incessant variations which can take place externally. This **maintenance of constancy** is a vital condition for **cells**, in which life **activities** take place. The intra-cellular milieu, while different from the internal milieus of the **organism**,

maintain continuous exchanges with them, and they also are kept constant. Claude BERNARD was the first to recognize this **constancy**, which was to be discussed later by CANNON (1932) in America under the term "Homeostasis" (1989, p.146)

Very numerous biophysical, biochemical and physiological examples of homeostasis have been discovered since BERNARD's, CANNON's and VENDRYES' work, as for example the **adjustment** of the pupil to the intensity of light, the **stabilization** of the cardiac **rhythm**, the **level** of glucose in the blood, etc...

Homeostasis can also be observed more generally in human systems (families, enterprises, **organizations**, nations, etc.) in which cases the term "**dynamic stability**" is more readily used. In some cases, as for instance, in G. BATESON's **double-bind**, homeostasis may become pathological.

Still, the homeostasis **concept** is somehow **mechanicist**: L.von BERTALANFFY wrote: "Although the homeostasis **model** transcends older **mechanistic models** by acknowledging directiveness in **self-regulating** circular **processes**, it still adheres to the **machine** theory of the **organism**" (1962, p.8).

Homeostasis can be maintained only within the **limits** of the **theorem of minimum entropy production** which, in PRIGOGINE words asserts that: "(in the **linear** region) a system evolves towards a **stationary state** characterized by the **minimum entropy production** compatible with the **constraints** determined by the **boundary** conditions" (1985, p.5). There is however a **nonlinear region** where a **bifurcation** takes place after ever widening **fluctuations**. In this **region**, the homeostasis **concept** is no more valid. This is generally a very important caveat, specially for social systems.

H. MATURANA and F. VARELA's concept of **organizational closure** is clearly related to homeostasis. It offers a model of an internal iterative **mechanism of maintenance** of the system's **identity** allowing for **circuits** of specific **states**. However, **organizational closure**, at its high **level of abstraction**, minimizes (or even in some authors, ignores completely) the challenging role of the **environment**.

Homeostasis is normally a result of a **set** of complex adaptive conditions, as for example arterial pressure, breathing **rhythm**, body temperature, etc..., among interacting **processes**, alternating according to necessities.

Of course, even a homeostatic system has a limited **tolerance** to **changes** in external conditions. Human systems are however able to enhance this **tolerance** by modifying their **environment**, at least up to a certain point.

Homeostasis is, at least, a property of biological, ecological and **social systems**, and probably of many physical systems.

W. KÖHLER writes: "W. CANNON ...prefers to give the name *homeostasis* to the fact that certain *steady states* are so obstinately preserved or re-established in the **organism**. **Equilibria**, he adds, are found in simple **closed systems**, where known forces are balanced. Again, he says, the word homeostasis *does not imply something set and immobile, a stagnation*" (1969, p.61).

(Let us remember how necessary it is to distinguish **open, closed and isolated systems** from each other – see corresponding entries).

L.von BERTALANFFY interpretes CANNON in the following way: "Homeostasis according to CANNON, is the ensemble of organic **regulations** which act to maintain the **steady state** of the **organism** and are effectuated by **regulating mechanisms** in such a way that they do not occur necessarily in the same, and often in opposite, direction to what a corresponding external **change** would cause according to physical laws. The simplest example is homeothermy" (1962, p.6).

Shortly, homeostasis is a dynamical property entailing an uninterrupted **sequence** of transient quasi-**equilibria** around an **optimum**, and not a static **equilibrium** that could be reached once and for all.

KÖHLER states: "From the point of view of physics it is, therefore, simply impossible to state it as a **rule** that **transformations in organisms** occur in the direction of **equilibria**" (ibid.).

It should however be noted that the final **state** of a system, when it becomes unable to produce adaptive **fluctuations**, is a static **equilibrium** (rigor mortis), in any case absolutely transient, since it is immediately followed by a **process** of decomposition and scattering of the **elements**.

As noted by St. BEER: "One of the key features of any **viable system**, and a sure index of its submission to **control**, is that it can maintain a homeostatic **equilibrium**... And this is surely true also of the industrial, social and economic systems with which managers have to deal" (1968, p.289).

In relation to homeostasis in **social systems**, we find in the MERRIAM – WEBSTER Dictionary the following definition: "A tendency toward **maintenance** of relatively **stable** social conditions among **groups** with respect to various factors (as food supply and **populations** among animals) and to competing tendencies and powers within the body politic, to society, or to culture among men" (1961, p.1083).

However, some of the greatest question marks of our time are: Are our contemporary societies still homeostatic, at least up to a point? Will they become homeostatic again in the future? And if not, what could be the outcome of our present **instabilities**?

HOMEOSTASIS: its ways and costs¹⁾

Homeostasis is obtained through **regulation**.

W.D. GROSSMANN and K.E.F. WATT explains: "A **feedback loop** is the classical example of homeostasis. Two types of homeostasis exist. One happens within the existing **structures** and is actually generated by these **structures**, in particular by **feedback processes**" (1992, p.10).

Repeated **feedback processes** implies the existence of a **regulator**.

The same authors pursue: "The other is a reaction by the system which causes a **change** in the systems **structures**" (Ibid).

This case corresponds to the progressive institution of the **regulator**.

Still: "The capability for homeostasis is enhanced, the shorter the **time-lag** from the moment the system experiences a **perturbation** or threat to its **viability**, to the moment it respond appropriately... The speed with which systems can respond depends on the availability of **resources** to perform the **response**" (Ibid). This corresponds to VENDRYES' concept of "**reserve**".

Homeostasis does not of course come free. The different needed types of **regulations** have an **energetic cost**.

H. ODUM expresses it this way: "Some **energy** must go into **storages** which may be necessary for **structure** or for smoothing out fluctuating power supplies. Some **energy** must go into the work of gathering **input flows**, and some **energy** must insulate and control the relation of other **circuits**. Special **energies** overcome special **limiting factors**, such as material shortages, poisons or the seasonal **fluctuations**. Finally, special **energies** may be required to pump out excess **wastes**. (1971, p.88).

However, homeostasis is merely the **behavior** of **dynamically stable systems**, generally mature ones. Systems in course of **differentiation**, **dissipative structuration**, **bifurcation**, **emergence**, etc... are definitely *not* homeostatic, and the use of the concept in these cases lead to gross misunderstandings. This point was already made by L.von BERTALANFFY in his book "General Systems Theory" (1968)

Two other concepts complement homeostasis. One, which did not become widely accepted, was W. CANNON's **heterostasis**. The other one is C. WADDINGTON's **homeorhesis**, applied to systems in their period of **growth** towards maturity.

1576

HOMEOSTASIS²⁾⁵⁾ (A critical view in relation to chaos)

In biology, homeostasis should possibly be relativized.

Marc BUCHANAN writes: "Homeostasis holds that when the body is pushed out of balance, it will compensate as to maintain **equilibrium**. In a sense, this does happen in the heart - it is the dynamic behind the long range anticorrelations discovered by PENG and his colleagues. But in the homeostatic view, the healthy **state** of the body tries to remain in a **static equilibrium**. So the heart rate should stay constant, as should blood pressure and other physiological **variables**".

This is probably a too narrow understanding of homeostasis. In opposition to **constancy**, homeostasis equals "**fluctuations** within **limits**".

Within such **limits** "the **fluctuations** are highly irregular, though far from **random**" (1998, p.25).

"But why should health be equated with irregularity? For one thing, it could make the **organism** more adaptable. A **chaotic system** is poised in a **state** in which it is very sensitive to small influences. That make it easy for the heart to respond quickly and flexibly to changes in the demands of the body" (Ibid)

Thus, with a closer look, homeostasis is a **chaotic phenomenon**, i.e. only **deterministic** in a broad sense.

1577

HOMEOSTAT²⁾

A device created by W.R. ASHBY to demonstrate some properties of the **ultrastable systems**.
